Duration of symptoms: Although UC can present acutely, symptoms are usually present for weeks to months.

Exacerbations and remissions: They are characteristic features. Relapses are provoked by emotional stress, intercurrent infection, gastroenteritis, antibiotics, or NSAID therapy.

Q. Write short note/essay on extraintestinal manifestations of ulcerative colitis.

Extraintestinal manifestations (*refer* **Table 5.57** and **Fig. 5.15**).

Risk of carcinoma colon: The incidence is high, especially in patients with total colitis, disease of more than 10 years duration and early age of onset.

Signs:

- Tenderness on palpation directly over the colon, especially in the left iliac fossa.
- Signs of proctitis include tender anal canal and blood on rectal examination.
- *Signs of toxic megacolon:* It is a serious complication and its signs include severe pain and bleeding, and signs of peritonitis, if there is associated perforation.

Investigations

Q. Write short essay/note on investigation of ulcerative colitis.

They are required for confirmation of the diagnosis, know the distribution and activity, and identify complications.

Laboratory findings

- **Anemia:** Decrease in hemoglobin may be due to blood loss or malabsorption (nutritional deficiencies) of iron, folic acid, or vitamin B_{12}. It may be associated with raised platelet count.
- **Raised ESR and acute-phase reactants** [C-reactive protein (CRP)], are nonspecific serum inflammatory markers and are observed during exacerbations. They are sometimes used to monitor the activity of disease.
- **Total WBC count:** Moderate leukocytosis is observed in active disease, but a marked leukocytosis suggests an abscess or another suppurative complication.
- **Hypoalbuminemia:** Reduced serum albumin concentration may be due to protein-losing enteropathy, inflammatory disease, or malnutrition (poor nutrition).
- **Stool examination**
  - *Stool microscopy and culture:* To exclude infective pathology and *C. difficile* toxin.
- Blood cultures in patients with septicemia.
- **Serological tests:** These are supportive and not used independently as markers for diagnose IBD.
  - ***Anti-Saccharomyces cerevisiae* antibodies (ASCA):** These are antibodies to yeast. They are observed in 40–70% of patients with Crohn's disease and in less than 15% of patients with ulcerative colitis. Presence of raised ASCA immunoglobulin A (IgA) and IgG titers is highly specific for Crohn's disease.
  - **Perinuclear antineutrophil cytoplasmic antibodies (pANCA):** They are detected in 10–20% of colon-predominant Crohn's disease, and in 55–70% of patients with ulcerative colitis.
  - **Antigoblet cell autoantibodies:** Found in 30–40% cases of ulcerative colitis and Crohn's disease.

- **Other tests:**
  - **Fecal lactoferrin:** It is a very sensitive and specific marker for detecting intestinal inflammation.
  - **Fecal calprotectin:** Its levels correlate with inflammation and helpful in predicting relapses.

Endoscopy

Endoscopy with mucosal biopsy is the gold standard investigation for ulcerative colitis.

Colonoscopy: For mild-to-moderate disease and patient not having an acute flare, colonoscopy is preferable to flexible sigmoidoscopy because it can assess the disease extent and activity. Colonoscopy helps in assessing the extent and activity of ulcerative colitis.

Sigmoidoscopy:

- **During early phase of the mild disease:** (1) Uniform continuous involvement of the mucosa, (2) diffuse mucosal erythema/hyperemia, (3) loss of the normal mucosal vascular pattern, granularity, and edema, and (4) exudate of mucus, pus and blood on the mucosa.
- **As the disease becomes severe:** Mucosa becomes more friable, bleeds easily on touch, and may ulcerate. Pseudopolyps represent epithelial regeneration and may develop after recurrent attacks in patients with long-standing disease.

Biopsy

Histological changes develop more slowly than clinical features. Biopsies help in diagnosis and to know the disease extent. Rectal biopsy shows mucosal inflammation and histological abnormalities are most severe in the distal colon and rectum.

Chromoendoscopy: Used for diagnosis of dysplasia in patients with long-standing UC.

Radiological features

- **Plain abdominal X-ray:** Useful to exclude toxic dilatation of colon.
- **Barium enema in ulcerative colitis:**
  - Earliest change in UC: Fine mucosal granularity
  - Later, the mucosa shows thickening and superficial ulcers. Deep ulcers appear as 'collar-button' ulcers, which indicate that the ulcer has penetrated the mucosa.
  - Haustral folds may be normal in initial phase of the disease, but later become edematous and thickened.
  - Long-standing disease may show loss of haustration, pseudopolyps, narrowing and shortening of the colon.
- **CT scan:** It is not so helpful when compared to endoscopy and barium enema in UC. CT scanning shows: mild mural thickening (<1.5 cm), inhomogeneous wall density, no thickening of small bowel, increased perirectal and presacral fat and target appearance of the rectum.

Biochemical abnormalities

- Electrolyte abnormalities
- Abnormal liver function tests

Q. Discuss severity staging of ulcerative colitis.

Q. Write short essay/note on management of ulcerative colitis.

Q. IM16.16 Describe and enumerate the indications, pharmacology, and side effects of pharmacotherapy in UC, including immunotherapy.

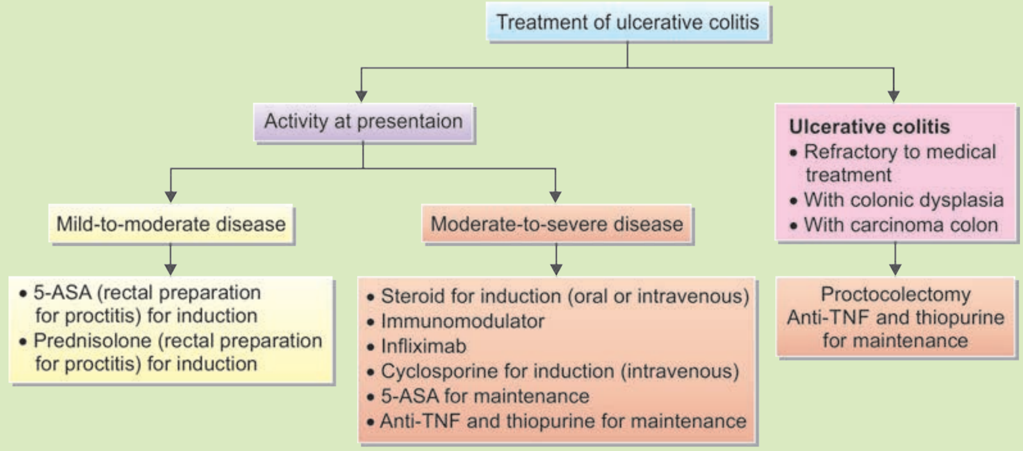
Treatment (Flowchart 5.10) of Ulcerative Colitis

Whenever possible, IBD should be approached by a multidisciplinary team consisting of physicians, surgeons, radiologists, and dietitians. IBDs are life-long conditions and have psychosocial implications. Truelove and Witts' severity index of ulcerative colitis is presented in **Table 5.49**.

TABLE 5.49: Truelove and Witts' severity index of ulcerative colitis.

Features	*Mild*	*Moderate*	*Severe*
Bowel movements (number per day)	Fewer than 4	4–6	6 or more plus at least one of the features of systemic upset (marked with * below)
Blood in stools	No more than small amounts of blood	Between mild and severe	Visible blood
Pyrexia (temperature greater than 37.8°C)*	No	No	Yes
Pulse rate greater than 90 bpm*	No	No	Yes
Anemia*	No	No	Yes
Erythrocyte sedimentation rate (mm/hour)*	30 or below	30 or below	Above 30

FLOWCHART 5.10: Algorithm for treatment of ulcerative colitis.



Treatment of ulcerative colitis
Activity at presentaion
Ulcerative colitis
• Refractory to medical treatment
• With colonic dysplasia
• With carcinoma colon
Mild-to-moderate disease
Moderate-to-severe disease
• 5-ASA (rectal preparation for proctitis) for induction
• Prednisolone (rectal preparation for proctitis) for induction
• Steroid for induction (oral or intravenous)
• Immunomodulator
• Infliximab
• Cyclosporine for induction (intravenous)
• 5-ASA for maintenance
• Anti-TNF and thiopurine for maintenance
Proctocolectomy
Anti-TNF and thiopurine for maintenance

(5-ASA: 5-aminosalicylate agents; TNF: Tumor necrosis factor)

Medical Management of UC

- Aims of medical therapy (**Box 5.14**)
- **`5-Aminosalicylate (5-ASA) agents (Table 5.50):**
  – Available as oral tablets or topical (enema/suppository) preparation (for rectal and sigmoid disease).
  – These agents include 5-aminosalicylic acid (5-ASA) or mesalazine alone, or combination of 5-ASA with a carrier which releases 5-ASA after splitting by bacteria in colon (sulfasalazine, olsalazine, and balsalazide).
  – Topical mesalazine is the initial preferred agent in mild-to-moderate. Ulcerative proctitis/proctosigmoiditis, for induction as well as maintenance of remission. It acts as a topical anti-inflammatory within the lumen of the intestine, controls acute exacerbation, maintains remission, and prevents relapses. Maintenance therapy may decrease the risk of colorectal cancer.
  – Patients who are unwilling or unable to tolerate topical mesalazine can be started an oral 5-ASA medication. Oral 5-ASA should also be added in those patients who do not show remission after 4 weeks of topical therapy.
  – For patients with left-sided or extensive mildly-to-moderately active UC a combination of an oral 5-ASA agent plus rectal mesalazine is used. **Sulfasalazine** and high dose **mesalazine** are the most frequently used oral agents. Sulfasalazine is the combination of a sulfapyridine (acting as a "carrier" that allows 5-ASA to be delivered into the colon) with 5-ASA (active agent). Side effects include: nausea, dyspepsia, hair loss, headache, worsening diarrhea, and hypersensitivity reactions.
  – Sulfa-free aminosalicylate preparations (e.g., olsalazine and balsalazide): They deliver higher amounts of the active ingredient of sulfasalazine (5-ASA, mesalamine) to the site of active disease in the bowel and have limited systemic toxicity.
  – Remission is usually within 2–4 weeks of therapy. If remission is not induced with oral/topical ASA combination within 2–4 weeks, then a topical steroid (Budesonide) is added.

Box 5.14: Aims of medical therapy in ulcerative colitis.

- Treat acute attacks and reduce inflammation
- Prevent relapses and maintain clinical remission
- Detect carcinoma at an early stage
- Select patients for surgery

TABLE 5.50: Various oral 5-ASA (5-aminosalicylate agents) preparations used in ulcerative colitis.

Preparation	***Dosage***
Azo-bond	
Sulfasalazine	3–6 g (acute) 2–4 g (maintenance)
Olsalazine	1–3 g
Balsalazide	6.75–9 g
Delayed-release	
Mesalamine	2.4–4.8 g (acute) 1.6–4.8 g (maintenance)
Controlled-release	
Mesalamine	2–4 g (acute) 1.5–4 g (maintenance)
Delayed and extended-release	
Mesalamine	1.5 g (maintenance)

Corticosteroids

- Oral or parenteral corticosteroids are beneficial in inducing remission in moderate-to-severe ulcerative colitis.
- They have no role in maintaining remissions. During clinical remission, steroids should be tapered according to the clinical activity.

Local Treatment

- Topical applications of steroid are also beneficial for distal colitis and as an adjunct in patients with involvement of rectal involvement associated with involvement of proximal colon.
- Hydrocortisone or prednisolone enemas, suppositories or foam may control active disease. Budesonide-MMX uses colonic release technology to extend the application of budesonide throughout the colon.
- **Duration of treatment:** 3–6 weeks.

Systemic Treatment

- **Oral:** Active UC that is unresponsive to 5-ASA therapy is treated with oral prednisone at doses of 40–60 mg/day for 3–6 weeks.

- **Parenteral:**
  - **Intravenous:** Hydrocortisone 300 mg/day or methylprednisolone, 40–60 mg/day are given as a constant infusion in severe cases.
  - **Intramuscular or subcutaneous injection:** Long-acting corticotrophin is used in the treatment of relapses.
- **Tapering of dose:** Steroids once started are gradually tapered and withdrawn, normally at a rate of no more than 5 mg/week.

Antibiotics

No role in the treatment of active or quiescent UC.

Immune Modulators

Indications:

- Patients who remain symptomatic despite 5-ASA therapy.
- Patients who have moderate-to-severe ulcerative colitis.

Drugs

1. **Azathioprine and 6-mercaptopurine (6-MP):**
   - *Usefulness are as follows:*
     - Patients who require two or more corticosteroid courses within a year.
     - Relapse of disease as the dose of prednisolone is reduced below 15 mg.
     - Relapse within 6 weeks of stopping corticosteroid.
   - *Dosage:* Azathioprine 2–3 mg/kg/day and 6-mercaptopurine 1.5 mg/kg/day.
   - *Disadvantage:* Slow clinical response and may not be evident for as long as 12 weeks.
   - *Side effects:* These include allergic reactions, pancreatitis, myelosuppression, infections, hepatotoxicity, and malignancy (lymphoma).
2. **Methotrexate:** It is a folic acid antagonist useful in patients who do not respond to azathioprine.
3. **Cyclosporine (CSA):** It inhibits both the cellular and humoral immune systems. CSA blocks the production of IL-2 by T-helper cells. CSA prevents activation of T cells by inhibiting calcineurin and indirectly inhibits B cell function by blocking helper T cells.
4. **Tacrolimus:** It is a macrolide antibiotic with immunomodulatory properties similar to CSA.

Biologics

Used to treat moderately to severely active ulcerative colitis that has responded inadequately to conventional therapy including corticosteroids and mercaptopurine or azathioprine, or who cannot tolerate, or have contraindications for, such therapies. Common side effects include headaches, nausea, vomiting, diarrhea, skin rash, weight gain from fluid retention, muscle aches, etc. Another important side effect is reactivation of TB. Hence, prior screening for dormant/active TB is mandatory. Screening is using Mantoux test or Quantiferon-TB Gold assay (in WHO—BCG Vaccine countries).

Drugs

1. **Ant-TNF agents: Infliximab** (given IV) is the most commonly used agent. Antitumor necrosis factor (anti-TNF) therapy can prevent or reduce rates of colectomy. Other agents include adalimumab and golimumab (both given subcutaneously).
2. **Vedolizumab**—MAB against aplha-4/beta-7 integrin. Preferred in elderly (>65 years), and those with history of malignancy or infectious complications.
3. **Ustekinumab**—MAB against interleukin 12/23.

Small Molecule Drugs

Tofacitinib—oral small molecule Janus kinase inhibitor, used for treating adults with moderate to severe UC who have failed or are intolerant to anti-TNF agent-based therapy.

General supportive measures

- *Parenteral nutrition:* It is necessary in seriously ill patients and parenteral broad-spectrum antibiotics may be required in septicemia.
- Correction of dehydration and electrolyte imbalance
- Antispasmodic medications and antidiarrheal (loperamide) for mild diarrhea (to be avoided in severe colitis).

Surgical management (Table 5.51)

- Surgery involves removal of the entire colon (colectomy) and rectum and is a curative procedure. It is indicated UC does not responded adequately to medical therapy. Emergency colectomy may be necessary for toxic megacolon.
- Elective surgical procedure is either panproctocolectomy with ileostomy, or proctocolectomy with ileal-anal pouch anastomosis.

Follow-up

- Extensive colitis of more than 10 years duration: Colonoscopy with multiple biopsies is recommended every 3 years to assess for dysplasia or malignant changes.
- UC for more than 20 years*:* Colonoscopy is recommended every 2 years. Biopsies from entire colon and samples from suspicious areas. If the biopsy shows high-grade dysplasia, total colectomy is performed.

Q. IM16.17 Describe and enumerate the indications for surgery in inflammatory bowel disease.

TABLE 5.51: Indications for surgery in ulcerative colitis.

Intractable/ extensive colitis	Toxic megacolon	Colonic perforation
Severe colonic hemorrhage	Colon cancer prophylaxis	Colon dysplasia/ cancer
Frequent relapses	Chronic damage to bowel-strictures	

Crohn's Disease

Q. Discuss the etiology, pathology, clinical features, investigations, and management of Crohn's disease.

Etiology and Pathogenesis

Refer etiology and pathogenesis of IBD.

Pathology

Gross

- **Site (Fig. 5.14):** It can involve any area of the gastrointestinal (GI) tract from mouth to anus. Unlike UC, rectum is spared in CD. Most commonly involved sites are:
  - Terminal ileum and right side of colon (40–55%)
  - *Small intestine/bowel disease alone (30–40%):* Terminal ileum alone or ileum and jejunum.
  - Colon alone (15–25%)

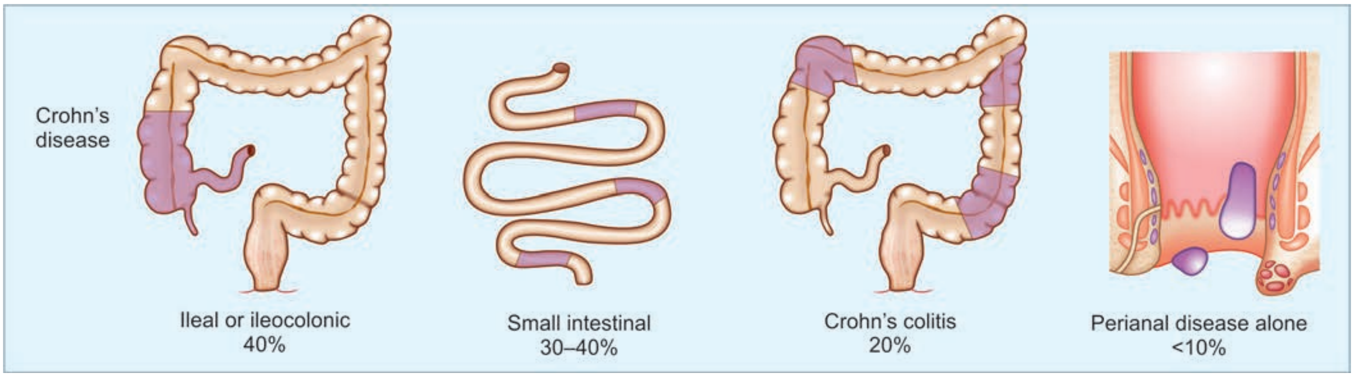


FIG. 5.14: Patterns of distribution in Crohn's disease.

- **Number of lesions:** Usually, the lesions are **multiple.**
- **Skip lesions:** The intestinal involvement is **discontinuous in which inflamed segments of intestine are** sharply demarcated/**separated by apparently normal** intervening bowel/**intestine** in between**.**
- **Intestinal wall:** The involved intestinal wall shows **fibrotic thickening and is rubbery** and appears like a hosepipe and produces a characteristic radiological sign known as the "**string sign**".
- **Transmural inflammation:** Inflammation involves all layers of the bowel wall.
- **Mucosal lesions***:* The earliest lesion is the **aphthous ulcer** which becomes deeper, transmural, and discrete. Multiple lesions may coalesce longitudinally to form linear or **serpentine** (snake-like**)** ulcers and produce characteristic "**cobblestone"** appearance. Later the ulcer becomes deeper and form linear clefts or **fissures.** Similar to UC, pseudopolyps may also form in CD.
- **External surface:** The fat may encircle around the antimesenteric serosal surface producing a pattern known as **creeping fat**.
- **Adhesion and fistulae:** Involved loops of bowel are often adherent to each other. **Fissures** frequently develop between mucosal folds. They may extend deeply to become **fistula tracts or sites of perforation**. These fistulas may also penetrate from the bowel into other organs, including the bladder, uterus, vagina, and skin.

Microscopic features

- **Chronic inflammation** by **lymphocytes, plasma cells, and macrophages**
- **Mucosal ulcerations:** They are small, superficial (aphthous ulcers).
- **Crypt abscesses:** Clusters of neutrophils within a crypt and are often associated with crypt destruction**.**
- **Noncaseating granulomas**

Clinical Features of Crohn's Disease

Symptoms due to involvement of small intestine or ileum and right colon (ileocolitis). CD present with one of two patterns of disease: (1) penetrating fistulous pattern or (2) fibrostenotic obstructing pattern. The clinical manifestations depend on the site of disease.

- Crohn's disease is a chronic disease with exacerbations and remissions.
- Major symptoms include abdominal pain (typically in the right lower quadrant), diarrhea, and weight loss (due to malabsorption and patients avoid food because eating provokes pain).
- Ileal Crohn's disease may cause subacute or acute intestinal obstruction and patients present with recurrent episodes of colicky abdominal pain, abdominal distention, nausea, vomiting, and excessive borborygmi.
- Sparing of rectum and the presence of perianal disease are observed in about 30% of patients in the form of fistulas, abscesses, fissures, and skin tags. It presents with pain, discharge, and fever (if there is an abscess).

Physical examination

- Signs depend on the location and severity of the disease process.
- Abdominal tenderness in the right lower quadrant (classical), accompanied by fullness, guarding, or a mass depending on the severity of inflammation.
- Palpable mass per abdomen and rectally reflects adherent loops of intestine and abscess.
- Features of malabsorption such as weight loss and anemia (iron, folic acid, and vitamin B_{12} malabsorption)
- Sodium, potassium, water, magnesium and zinc deficiency may develop due to chronic diarrhea.
- Stool usually does not show frank blood, mucus or pus unless colon is involved.
- Oral ulcers

Investigations

- **Anemia:** Anemia may result from chronic disease, blood loss or nutritional deficiencies of iron, folate, or vitamin B_{12}. It may be normochromic normocytic or macrocytic or hypochromic anemia depending on the deficiency/cause.
- **Leukocytosis:** Modestly raised leukocyte count indicates active disease, but a marked leukocytosis suggests an abscess or other suppurative complication.
- **Raised ESR (erythrocyte sedimentation rate) and C-reactive protein:** They are nonspecific serum inflammatory markers and may be used to monitor the activity of disease.
- Abnormal liver function tests
- **Hypoproteinemia/hypoalbuminemia:** Indication of malnutrition.
- **Malabsorption:** Ileal disease results in malabsorption of vitamin B_{12} (reduced serum vitamin B_{12} level) and Schilling test is done to determine the malabsorption of vitamin B_{12}.
- **Serologic markers:** They are supportive but may not independently used for the diagnose IBD.
  - **Anti–*Saccharomyces cerevisiae* antibodies (ASCA):** These are antibodies to yeast, are present in 40–70% of patients with Crohn's disease (positive in only 10–15% cases of ulcerative colitis).
  - **Perinuclear antineutrophil cytoplasmic antibodies (pANCA):** They are present in 20% of patients with CD (colon predominant disease), and in 55% of patients with ulcerative colitis.
  - Antigoblet cell autoantibodies in 30–40% cases of Crohn's disease.
  - Antiglycan antibodies in about 40–50% cases (e.g., antilaminaribioside, antimannobioside antibodies).
- **Stool examination:** Stool microscopy and culture to exclude infectious causes of diarrhea.
- **Sigmoidoscopy and colonoscopy in Crohn's disease:**
  - Segmental inflammation with normal mucosa between (skip lesions).
  - Discrete, aphthous, or deep ulcers and occasionally connected to one another, forming longitudinal stellate, serpiginous, and linear ulcers.
  - Perianal disease (fissures, fistulas and skin tags) or sparing of the rectum.
  - Strictures are common.
  - Biopsy of involved region (e.g., colonic mucosa, ileal mucosa, anal skin tags, and perianal inflammatory lesions) shows typical noncaseating granulomatous inflammation (tuberculosis must be excluded) and infiltration by lymphocytes and plasma cell.
  - Wireless capsule endoscopy (WCE) allows direct visualization and identification of inflammation in the entire small bowel mucosa. However, it should be avoided in the presence of small bowel strictures.

Radiological findings in Crohn's disease

Barium meal follow thorough and barium enema

- *Early radiographic findings in the small bowel:*
  - Thickened folds and aphthous ulcerations
  - Cobblestone appearance of mucosa resulting from longitudinal and transverse ulcerations.

- *More advanced disease:*
  - Transmural inflammation leads to decreased luminal diameter and limited distensibility.
  - Rigidity of involved segments and multiple strictures.
  - As ulcers progress deeper, they can lead to fistula formation. Radiographic "String sign" is due to long areas of transmural inflammation and fibrosis, producing narrowing of lumen of involved small intestine.
  - *Segmental nature of CD:* It results in wide gaps of normal or dilated bowel between involved segments (skip lesions).
  - Inflammatory masses and abscesses may be found.
  - Fistulous tracts

High-resolution ultrasound and spiral CT scanning

It helps in defining thickness of the bowel wall and intra-abdominal abscesses.

Radionuclide scan

Using gallium-labeled polymorphs or indium-labeled leukocytes identify intestinal and colonic disease and localize extraintestinal abscesses.

Q. Discuss Crohn's disease severity index.

Crohn's Disease Activity Index

Clinical and laboratory variables	*Weightage*
Number of liquid or soft stools each day for 7 days	× 2
Abdominal pain/graded from 0–3 on severity each day for 7 days	× 5
General well-being subjectively assessed from 0 (well) to 4 (terrible) each day for 7 days	× 7
Presence of complications* *One point each is added for each set of complications: ➢ The presence of joint pains of frank arthritis ➢ Inflammation of the iris or uveitis ➢ Presence of erythema nodosum, pyoderma gangrenosum, or aphthous ulcers ➢ Anal fissures, fistulae or abscesses ➢ Fever (>100°F) during the previous week	× 20
Taking Lomotil or opiates for diarrhea	× 30
Abdominal mass (0 as none, 2 as questionable, 5 as definite)	× 10
Absolute deviation of hematocrit from 47% in men and 42% in women	× 6
% deviation from standard weight	× 1

Remission of Crohn's disease is defined as a CDAI of less than 150. Severe disease was defined as a value of greater than 450.
Response defined as a fall of the CDAI of greater than 70 points.

Treatment (Flowchart 5.11)

Medical Management of Crohn's Disease

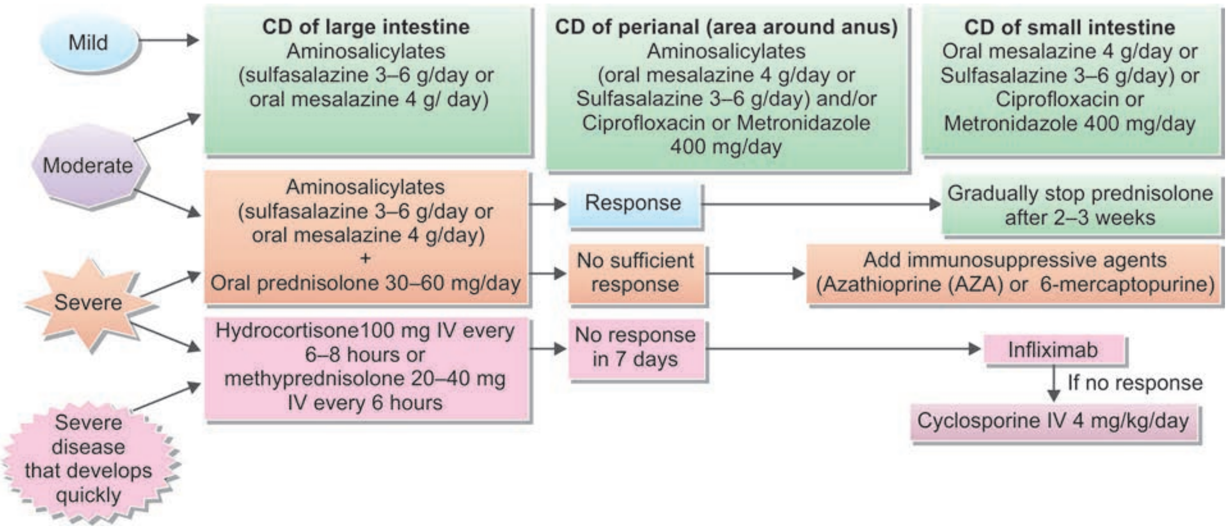
General Considerations

- Stop cigarette smoking
- Diarrhea can be controlled with loperamide, codeine phosphate, or co-phenotrope.
- Long-standing diarrhea may be due to bile acid malabsorption and is treated with bile salt sequestrants (e.g., cholestyramine).
- *Anemia:* Due to vitamin B_{12}, folic acid, or iron deficiency, should be treated accordingly.

Induction and Maintenance of Remission

- **Glucocorticosteroids:** Used to induce remission in moderate and severe Crohn's disease. Oral prednisolone 30–60 mg/day, which is gradually tapered and withdrawn. Mild-to-moderate ileocecal, CD should be treated by controlled-release steroids such as budesonide (9 mg by mouth once a day).
- **Aminosalicylates:** 5-ASA (e.g., mesalazine 4 g/day or sulfasalazine 3–6 g/day) as maintenance in mild-to-moderate ileocolonic disease. However, they are not effective for maintaining remission.
- **Antibiotics:** Ciprofloxacin and metronidazole 400 mg are used in abscess and perineal Crohn's disease.
- **Nutritional therapy:** Dietary antigens may stimulate the immune response in the intestinal mucosa. Bowel rest and total parenteral nutrition (TPN) are effective in inducing remission but are not effective as maintenance therapy. Enteral diets with a low fat and a low linoleic acid content (not palatable) may induce remission are similar to steroids.

FLOWCHART 5.11: Treatment approach to Crohn's disease.



Mild
Moderate
Severe
Severe disease that develops quickly
CD of large intestine
Aminosalicylates (sulfasalazine 3–6 g/day or oral mesalazine 4 g/ day)
CD of perianal (area around anus)
Aminosalicylates (oral mesalazine 4 g/day or Sulfasalazine 3–6 g/day) and/or Ciprofloxacin or Metronidazole 400 mg/day
CD of small intestine
Oral mesalazine 4 g/day or Sulfasalazine 3–6 g/day) or Ciprofloxacin or Metronidazole 400 mg/day
Aminosalicylates (sulfasalazine 3–6 g/day or oral mesalazine 4 g/day) + Oral prednisolone 30–60 mg/day
Response
Gradually stop prednisolone after 2–3 weeks
No sufficient response
Add immunosuppressive agents (Azathioprine (AZA) or 6-mercaptopurine)
Hydrocortisone100 mg IV every 6–8 hours or methyprednisolone 20–40 mg IV every 6 hours
No response in 7 days
Infliximab
If no response
Cyclosporine IV 4 mg/kg/day

- **Immunosuppressive agents:** Azathioprine (AZA) and its metabolite 6-mercaptopurine (6MP) and newer drugs (e.g., mycophenolate mofetil) suppress the proliferation of T- and B-lymphocytes. They are effective in inducing and maintaining remission and have steroid-sparing properties.
- **Biologic therapy:** Anti-TNF therapy is reserved for moderate-to-severe Crohn's disease that failed to respond to other therapies (infliximab, adalimumab, and peg certolizumab) and in CD with refractory perianal and enterocutaneous fistulas. Vedolizumab an integrin antibody is preferred in elderly and in those with malignancies or infectious complications. Another monoclonal antibody (mAb) ustekinumab (anti-IL-12/23) is used when standard anti-TNF therapy fails.

Maintenance of Remission

- Aminosalicylates
- Azathioprine, 6MP, and mycophenolate mofetil

Surgical Management (Table 5.52)

- **Small intestine:** Strictures can be widened (stricturoplasty)/ minimal resection and anastomosis.
- **Colorectal:**
  - Subtotal colectomy and ileorectal anastomosis, if rectum is spared.
  - Pancolectomy with ileostomy, if whole colon and rectum are involved

Assessment of severity of Crohn's disease is presented in **Table 5.53.**

TABLE 5.52: Indications for surgery in CD.

Small intestine	***Colon and rectum***
➤ Stricture and obstruction not responding to medical therapy ➤ Severe hemorrhage ➤ Refractory fistula ➤ Abscess	➤ Intractable/fulminant disease ➤ Perianal disease not responding to medical therapy ➤ Refractory fistula ➤ Colonic obstruction/perforation ➤ Colon dysplasia/cancer

TABLE 5.53: Severity of Crohn's disease.

Mild–moderate	***Moderate–severe***	***Severe/fulminant***
CDAI 150–220	***CDAI 220–450***	***CDAI >450***
Ambulatory Able to tolerate oral alimentation without manifestations of dehydration Systemic toxicity (high fevers, rigors, and prostration) abdominal tenderness painful mass Intestinal obstruction, or >10% weight loss	Failed to respond to treatment for mild–moderate disease or Has more prominent symptoms of fever, significant weight loss, abdominal pain or tenderness, intermittent nausea or vomiting (without obstructive findings), or significant anemia	Persistent symptoms despite treatment with corticosteroids/ biologics as outpatients Or Has high fevers, persistent vomiting, intestinal obstruction, significant peritoneal signs, cachexia or Abscess

(CDAI: Crohn's disease activity index)

Toxic Megacolon

Q. Give a brief account of toxic dilatation of colon (toxic megacolon).

Definition: Toxic megacolon is defined as a transverse or right colon with a diameter of greater than 6 cm, with loss of haustration.

Causes

- **Ulcerative colitis:** One of the most significant complications of UC. It can be triggered by electrolyte abnormalities, narcotics, antidiarrheal (diphenoxylate and loperamide) antispasmodics medications (reduce gastrointestinal motility), and barium enema.
- **Other rare causes:** (1) Diarrheas are due to *Clostridium difficile,* (2) *Campylobacter jejuni* gastroenteritis, (3) Shigellosis, (4) Chagas' megacolon, and (5) amebic colitis.

Clinical Features

- Features of severe colitis
- High fever, tachycardia, dehydration, electrolyte imbalance, and leukocytosis
- **Physical examination:** Patient is toxic and ill, postural hypotension, colonic dilatation, abdominal tenderness over the involved colon, and absent or hypoactive bowel sounds.
- **Plain radiograph of abdomen:** Shows colonic dilatation with transverse colonic diameter greater than 6 cm. Air may be observed in the wall of the colon.

Treatment

- *Medical therapy:* About 50% of cases will resolve with medical therapy alone
  - – Nil mouth, and nasogastric suction
  - – Intravenous fluids to replace water and electrolyte abnormalities
  - – Broad-spectrum antibiotics (e.g., ampicillinsulbactam) plus metronidazole
- Urgent colectomy may be necessary when there is no improvement with medical therapy

Complications

Perforation is the most dangerous of the local complications.

Complications of Inflammatory Bowel Disease

Q. Write short note on the complications of inflammatory bowel disease.

It may be local and systemic (extraintestinal).

Local Complications (Tables 5.54 and 5.55)

Conditions that mimic inflammatory bowel disease (ulcerative or Crohn's colitis) are presented in **Table 5.56**.

Extraintestinal Manifestations (Table 5.57 and Fig. 5.15)

Q. Write short note/essay on extraintestinal manifestations of inflammatory bowel disease.

TABLE 5.54: Local complications of Crohn's disease.

- ➢ **Fistula formation:** It may develop between loops of intestine and surrounding structures such as urinary bladder, vagina, and abdominal or perianal skin. Perforations and peritoneal abscesses are common
- ➢ **Stricture formation:** May produce intestinal obstruction
- ➢ **Iron-deficiency anemia** with colonic disease
- ➢ **Malabsorption:** Extensive involvement of the small intestine may result in loss of **protein and hypoalbuminemia, generalized nutrient malabsorption, or malabsorption of vitamin B_{12}, and bile salts**
- ➢ **Fibrosing strictures** in the terminal ileum are common
- ➢ **Acute complications:** Perforation abscesses and hemorrhage
- ➢ **Development of carcinoma** is rare**.** Risk of carcinoma colon is increased in patients with longstanding colonic disease
- ➢ Gallstones and **urinary oxalate stones**
- ➢ **Systemic secondary amyloidosis** rare

TABLE 5.55: Local complications of UC.

- ➢ **Toxic megacolon:** In fulminant cases, the inflammation and inflammatory mediators can damage the muscularis propria and disturb neuromuscular function. This may lead to colonic dilation and toxic megacolon, which may lead to perforation
- ➢ **Colorectal cancer:** Longstanding ulcerative colitis may develop colorectal cancer than the general population
- ➢ Hemorrhage leading to blood loss
- ➢ Electrolyte disturbances due to diarrhea

TABLE 5.56: Conditions that mimic inflammatory bowel disease (ulcerative or Crohn's colitis).

Infective

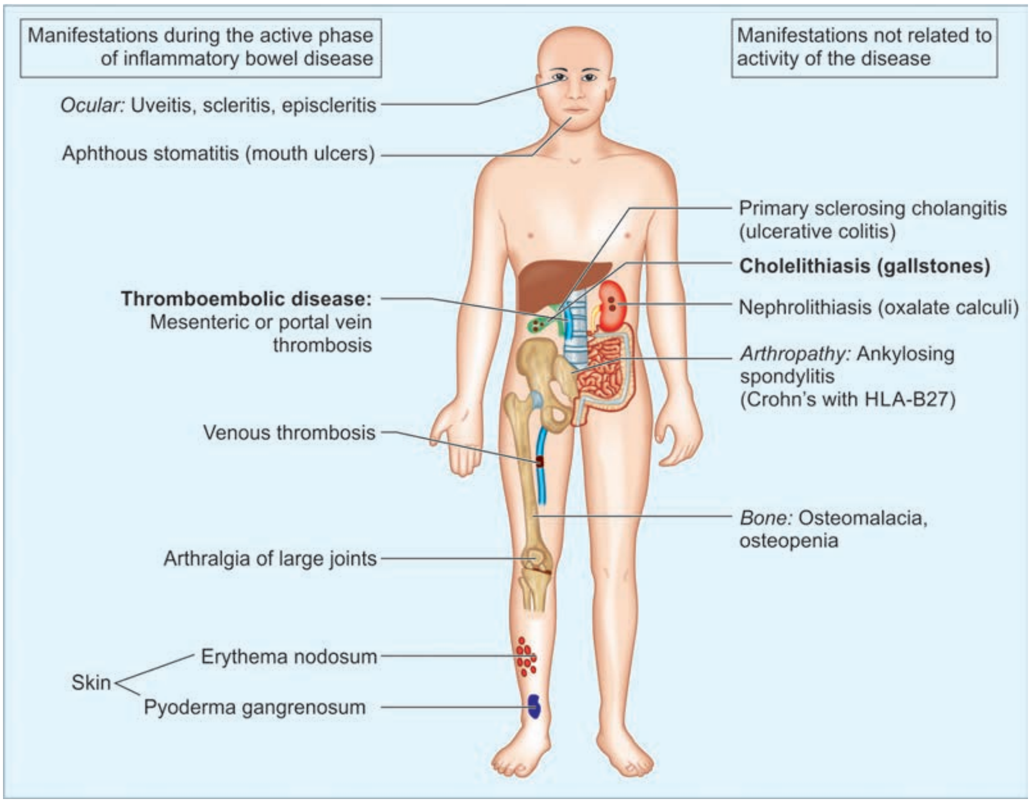
- ➢ **Bacterial:** *Salmonella*, *Shigella*, pseudomembranous colitis, *Campylobacter jejuni*, gonococcal proctitis, *Chlamydia proctitis E. coli* O157
- ➢ **Viral:** Herpes simplex proctitis, cytomegalovirus
- ➢ **Protozoal:** Amoebiasis

Noninfective

Ischemic colitis, collagenous colitis, radiation proctitis, Behcet's disease, diverticulitis, carcinoma colon, and NSAIDs

TABLE 5.57: Extraintestinal manifestations of IBD.

Complications	*Crohn's disease*	*Ulcerative colitis*
Ocular: Uveitis, scleritis, and episcleritis	+	+
Arthropathy: Pauciarticular, polyarticular, and ankylosing spondylitis	+	+
Skin: Erythema nodosum, pyoderma gangrenosum	+	+
Primary sclerosing cholangitis	+	+
Thromboembolic disease	+	+
Renal: Nephrolithiasis	+	+
Bone: Osteomalacia, osteoporosis	+	–
Oral ulcers	+	–
Vitamin B_{12} deficiency	+	–



Manifestations during the active phase of inflammatory bowel disease
Manifestations not related to activity of the disease
Ocular: Uveitis, scleritis, episcleritis
Aphthous stomatitis (mouth ulcers)
Primary sclerosing cholangitis (ulcerative colitis)
Cholelithiasis (gallstones)
Thromboembolic disease: Mesenteric or portal vein thrombosis
Nephrolithiasis (oxalate calculi)
Arthropathy: Ankylosing spondylitis (Crohn's with HLA-B27)
Venous thrombosis
Bone: Osteomalacia, osteopenia
Arthralgia of large joints
Skin
Erythema nodosum
Pyoderma gangrenosum

FIG. 5.15: Systemic complications of inflammatory bowel disease.

Differences between Ulcerative Colitis and Crohn's Disease of the Colon (Table 5.58)

Q. Write short note on the differences between ulcerative colitis and Crohn's disease of the colon.

PROBIOTICS AND PREBIOTICS

Q. PE24.5 Discuss briefly about probiotics and prebiotics.

Probiotics

Definition: Probiotics are defined as live microorganisms which are beneficial to its host. Throughout their journey in the digestive tract, they need to be intact, so they can reach the intestines where they act to give their beneficial effects to the body.

Nature

- **Bacteria:** Probiotics are usually bacterial components of the normal intestinal flora of human beings (e.g., *lactobacilli* and *Bifidobacterium infantis*). They produce lactate and short-chain fatty acids (e.g., acetate and butyrate) as end products of metabolism.
- **Yeast:** *Saccharomyces boulardii* is yeast.

Preparation

- **Yogurt:** It is commonly used probiotic in which is milk fermented by bacteria that convert lactose into lactic acid.

TABLE 5.58: Differences between ulcerative colitis and Crohn's disease of the colon.

Characteristics	*Ulcerative colitis*	*Crohn's disease*
Pathological features		
Involvement of bowel	Continuous involvement	Segmental involvement (skip lesions)
Inflammation	Restricted to mucosa and submucosa	Transmural
Noncaseating granulomas	Absent	Common
Crypt abscess	Common	Uncommon
Goblet cell depletion	Seen	Absent
Strictures, fissures and fistulae	Uncommon	Common
Mesenteric and lymph nodal involvement	Absent	Common
Clinical features		
Rectal bleeding	Common	Uncommon
Abdominal pain	Less common	More common
Abdominal masses	May be palpable	Not usually palpable
Fistulae, fissures and perianal skin tags	Uncommon	Common and characteristic
Small bowel involvement	Uncommon	Common
Rectal and colonic involvement	Common	Rare
Recurrence after surgery	Not common	Common
Toxic dilatation	Relatively common	Uncommon

- **Freeze-dried bacteria:** Probiotics are also available as freeze-dried bacteria (in capsule, tablet, or powder form). Their composition varies and most of them contain *Lactobacillus acidophilus* often with bifidobacteria. Other strains include *Bacillus coagulans*, *L. paracasei*, and *L. johnsonii*.

Limitations: Problems with quality control and formulation restrict the clinical availability of some probiotics.

Uses

- **Malnutrition:** Helps in normalizing the nutritional status of malnourished children. WHO suggested the use of yogurt in nutritional recovery.
- **Lactose intolerance:** Yogurt is preferred.
- **Prevention and treatment of antibiotic-associated diarrhea:** Probiotics containing *Saccharomyces boulardii* yeast may be useful to some extent.
- Irritable bowel syndrome (IBS) and colitis
- Improve immune function/immunity
- Necrotizing enterocolitis in neonates
- Speed treatment of certain intestinal infections
- Prevent and treat eczema in children
- Prevent or reduce the severity of colds and flu
- Prevent and treat vaginal yeast infections and urinary tract infections
- *Reduce bladder cancer recurrence:* Probably reduces the development of carcinoma of colon.

Prebiotics

Definition

Prebiotics are referred to as dietary fiber or carbohydrates that act as the food of probiotics. This is why it triggers bacterial growth and activity in the intestinal microflora. Therefore, it promotes good health of the host.

- Chemical substances (usually oligosaccharides) which beneficially nourish and act as a fertilizer to promote growth of the host's intrinsic probiotic bacteria. They encourage their growth.
- Prebiotics are special form of dietary fiber.
- Prebiotics are not digested (nondigestible) by the small intestine and nonmetabolized by nonprobiotic gut flora such as *Bacteroides* species and *Escherichia coli* present in the host.
- Synthetic prebiotics are oligosaccharides containing fructose or galactose, known as fructose oligosaccharides (FOS) and galactose oligosaccharides (GOS), respectively. Lactulose is also a prebiotic.
- These oligosaccharides are enriched with the combination of inulin.
- They may be added to foods, or combined with a probiotic.

Potential Uses of Prebiotics

See **Box 5.15**.

Box 5.15: Potential uses of prebiotics.

- Relief of constipation
- Reduce intestinal pH
- Restore intestinal bacterial balance
- Increase in the absorption of calcium and magnesium
- Effect on blood cholesterol level
- Reduction of fasting glucose level in type 2 diabetes patients
- Reduce risk on colorectal cancer
- Effects on the immune system
- Better intestinal flora in infants
  - Lactulose: Useful in hepatic encephalopathy
  - Prevention of osteoporosis: Prebiotics may increase calcium absorption
  - Chronic constipation

Synbiotics

- Synbiotics refer to the combination of the prebiotics and probiotics within a single product.
- Prebiotics are targeted to act on the large intestines while the probiotics are most effective in doing its role in the small intestine.
- The two agents have been said to act synergistically. So, the term synbiotics is used.

MISCELLANEOUS TOPICS

Gardner's Syndrome

- Condition in which familial adenomatous polyposis (FAP) is associated with predominant extraintestinal manifestations.
- Autosomal dominant disorder
- *Adenomatous polyps:* Numerous in colon and few in the stomach and duodenum

- *Extraintestinal lesions:* These include:
  - **Osteomas of mandible, skull, and long bones**
  - **Epidermal cysts, desmoid tumors, thyroid tumors, etc**.

Treatment: Prophylactic total colectomy.

Peutz-Jeghers Syndrome

- It is a rare autosomal dominant syndrome.
- Median age of presentation is 11 years
- It is characterized by:
  - **Multiple GI hamartomatous polyps:** Involves the entire GIT but are most common in the small intestine. Usually, present in the dozens.
  - **Mucocutaneous hyperpigmentation:** The melanotic pigmentation is seen in the mouth, buccal mucosa, and genitalia region.
- Peutz-Jeghers syndrome is associated with an **increased risk** of **several malignancies.** These include cancers of the colon, pancreas, breast, lung, ovaries, uterus, and testicles.
- **Genetics:** Inactivation (loss-of-function mutations) of the *STK11/LKB1* gene (tumor suppressor gene) detected in about 70% of affected families. The **hamartomas are not preneoplastic precursor lesions**.
- **Clinical presentation:** Abdominal pain, rectal bleeding, anemia, intestinal obstruction, and intussusception.
- **Diagnosis and treatment:** Intraoperative enteroscopy (IOE) and remove all small intestinal polyps by double balloon enteroscopy (DBE).

Indications, Contraindications and Complications of Upper Gastrointestinal Endoscopy (Table 5.59)

Q. IM16.12 List indications, contraindications, and complications of upper gastrointestinal endoscopy.

TABLE 5.59: Indications, contraindications, and complications of upper gastrointestinal endoscopy.

Diagnostic indications	**Therapeutic indications**
➢ *Upper gastrointestinal bleeding:* Past or present; acute or chronic patients with splenomegaly or suspected chronic liver disease: For presence and grading of esophagogastric varices ➢ Upper abdominal distress that persists despite an appropriate trial of therapy ➢ Dysphagia or odynophagia ➢ Esophageal reflux symptoms that are persistent or recurrent despite appropriate therapy ➢ Persistent nausea and vomiting of unknown cause surveillance for malignancy, abnormal CT scan or barium meal gastric or esophageal ulcers ➢ Familial adenomatous polyposis adenomatous gastric polyps Barrett's esophagus ➢ Occult gastrointestinal bleeding ➢ After caustic ingestion to assess for acute injury dyspepsia over 55 years of age or with alarm symptoms atypical chest pain ➢ Weight loss ➢ Duodenal biopsies in the investigation of malabsorption and to confirm a diagnosis of celiac disease prior to commencement of gluten-free diet	➢ Treatment of bleeding lesions ➢ Sclerotherapy or banding of varices ➢ Removal of foreign bodies ➢ Removal of selected polypoid lesions or superficial neoplasms ➢ Placement of feeding or drainage tubes ➢ Dilation of stenotic lesions ➢ Palliative treatment of stenosing neoplasms ➢ Drainage of pancreatic pseudocysts **Contraindications** ➢ **Absolute contraindications** – Severe shock – Possible visceral perforation ➢ **Relative contraindications** (can be performed by experienced hands) – Recent myocardial infarction, unstable angina, and cardiac arrhythmia – Severe respiratory disease – Atlantoaxial subluxation **Complications** ➢ Cardiorespiratory depression due to sedation ➢ Aspiration pneumonia ➢ Perforation

Indications for Colonoscopy (Table 5.60)

Q. List indications for colonoscopy.

Protein-losing Enteropathy

Q. Write short note on protein-losing enteropathy.

It is characterized by excessive loss of protein into the gut lumen, sufficient to cause hypoproteinemia.

Causes (Table 5.61): Most common in diseases with mucosal ulceration.

Clinical features: Peripheral edema and hypoproteinemia.

Investigations: Liver function tests are normal liver function and no proteinuria. Diagnosis can be confirmed by measuring fecal clearance of α1-antitrypsin or ^{51}Cr-labeled albumin after intravenous injection. Other investigations depend on the underlying cause.

Treatment of the underlying disorder, with nutritional support and measures to control peripheral edema.

TABLE 5.60: Indications for colonoscopy.

Diagnostic	***Therapeutic***
➢ Unexplained rectal bleeding ➢ Unexplained lower gastrointestinal symptoms and signs, such as recent onset constipation or feeling of incomplete evacuation, especially in the elderly ➢ Polyp and cancer screening or follow-up ➢ Inflammatory bowel disease ➢ Stricture or colonic narrowing (with and without inflammatory bowel disease) ➢ Diverticular disease ➢ Infectious colitis ➢ Radiation colitis ➢ Ischemic colitis ➢ Endometriosis ➢ *Pneumatosis cystoides intestinalis*	➢ Polypectomy ➢ Foreign body removal ➢ Dilation of strictures in colon or terminal ileum ➢ *Therapeutic:* Hemostasis ➢ Tumor resection (palliative) ➢ Colonic decompression (volvulus and pseudo-obstruction)

TABLE 5.61: Causes of protein-losing enteropathy.

With erosions or ulceration of mucosa: Crohn's disease, ulcerative colitis, cancer of esophagus, stomach or colon, radiation damage, and lymphoma
Without erosions or ulceration of mucosa: Menetrier's disease, celiac disease, bacterial overgrowth, eosinophilic gastroenteritis, systemic lupus erythematosus, and tropical sprue
With obstruction of lymphatics: Intestinal lymphangiectasia, lymphoma, Whipple's disease, and constrictive pericarditis

Generalized Abdominal Distension (Box 5.16)

Q. List causes of abdominal distension.

Box 5.16: Causes of abdominal distension (7Fs).

Fat, fluid (ascites), flatus (obstruction/ileus), fetus (pregnancy), feces (constipation), full bladder, fatal neoplasm (organomegaly)

Causes of Oral Ulceration

Q. List causes of oral ulceration and aphthous ulcer.

Aphthous Ulceration

Aphthous ulcers are superficial and painful ulcers which can develop in any part of the mouth. Recurrent ulcers are common in women prior to menstruation. The cause is unknown. Other causes of oral ulceration are presented in **Table 5.62**.

TABLE 5.62: Causes of oral ulcers.

➢ **Aphthous:** Idiopathic Infection, premenstrual ➢ **Infection:** Fungal (candidiasis), viral (herpes simplex, HIV), bacterial (e.g., syphilis, tuberculosis) ➢ **Drugs:** Nicorandil, NSAIDs (nonsteroidal anti-inflammatory drugs), methotrexate, cytotoxic drugs, Stevens–Johnson syndrome ➢ **Neoplasia:** Carcinoma, leukemia, Kaposi's sarcoma	➢ **Gastrointestinal diseases:** Crohn's disease, celiac disease ➢ **Dermatological conditions:** Lichen planus, dermatitis herpetiformis ➢ **Systemic diseases:** Systemic lupus erythematosus, Behçet's syndrome, vitamin deficiencies ➢ Traumatic ulcers

CHAPTER

6

Hepatobiliary System

FUNCTIONS OF LIVER

Q. Enumerate important functions of liver.

Important functions of liver are listed in **Box 6.1**.

LIVER FUNCTION TESTS

Q. PE26.9 Interpret liver function tests.

Liver Biochemistry

No single test alone can be used to assess liver function.

Q. PA25.1 Describe bilirubin metabolism, enumerate the etiology and pathogenesis of jaundice, distinguish between direct and indirect hyperbilirubinemia.

Box 6.1: Important functions of liver.

- Protein metabolism and urea formation
- Carbohydrate metabolism includes gluconeogenesis, glycogenolysis, and glycogenesis
- Lipid metabolism
- Bilirubin formation from hemoglobin degradation
- Metabolism of vitamins and minerals
- Hormone metabolism
- Drug and alcohol metabolism
- Cholesterol metabolism
- Bile acid formation and bile secretion
- Synthesis of plasma proteins including coagulation factors
- Immunological function—removal of gut endotoxins and foreign antigens
- Maintains core body temperature
- Maintains pH balance and correction of lactic acidosis

Serum Bilirubin

- Normal values of total serum bilirubin are between 0.3 and 1.3 mg/dL, with 95% of a normal population falling between 0.2 and 0.9 mg/dL (almost all unconjugated). Bilirubin is a degradation product of hemoglobin and hem-containing proteins. Bilirubin metabolism is summarized in **Figure 6.1**.
- Total serum bilirubin = Conjugated (direct) + unconjugated (indirect) bilirubin.

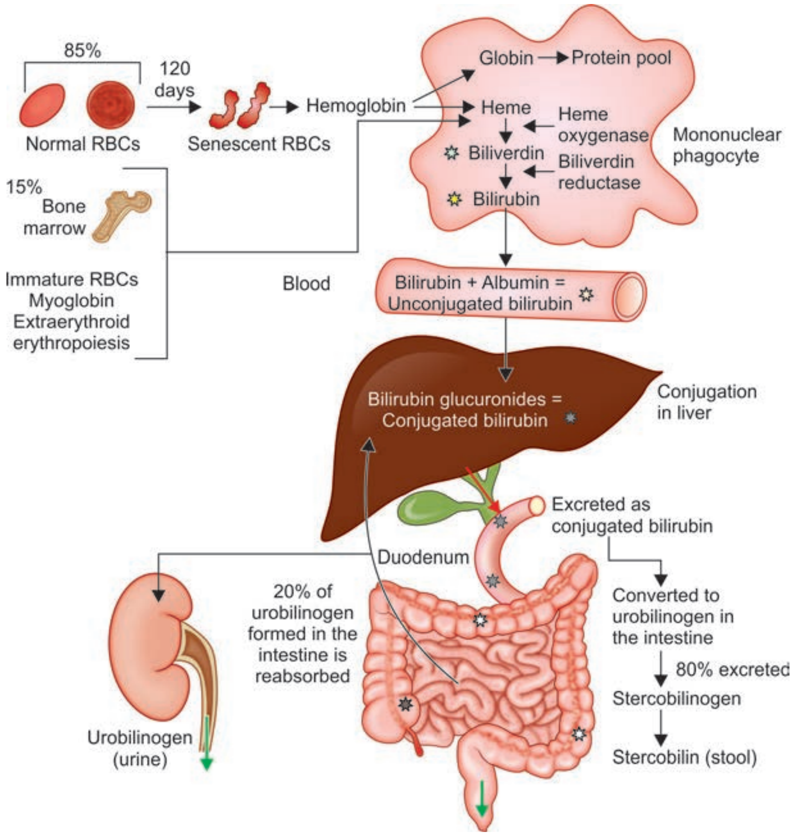
Type	*Bilirubin level*	*Causes*	*Bilirubinuria, liver function test (LFT)*
Unconjugated hyperbilirubinemia	Usually <6 mg/dL	➢ Hemolytic anemia ➢ Ineffective erythropoiesis ➢ Gilbert's syndrome	➢ Absent ➢ LFT otherwise normal
Conjugated hyperbilirubinemia	Higher levels	➢ Parenchymal liver diseases ➢ Biliary tract obstructions	➢ Present ➢ LFT deranged

- The presence of conjunctival icterus suggests a total serum bilirubin level of at least 3.0 mg/dL level below which is called **anicteric jaundice**, but does not allow differentiation between conjugated and unconjugated hyperbilirubinemia.
- Tea or cola-colored urine may indicate the presence of bilirubinuria and thus conjugated hyperbilirubinemia.
- **Fluctuating hyperbilirubinemia** is observed in gallstones, carcinoma of ampulla of Vater, chronic hepatitis, hemolytic anemias, and Gilbert's syndrome.

Serum Enzymes

Enzymes that reflect damage to hepatocytes—aminotransferases (transaminases):

- These enzymes are present in hepatocytes and leak into the blood with liver cell damage. These include two enzymes, namely: (1) aspartate aminotransferase (AST/SGOT) and (2) alanine aminotransferase (ALT/SGPT).



85%
120 days
Normal RBCs
Senescent RBCs
Hemoglobin
Globin
Protein pool

Blood
Bilirubin + Albumin = Unconjugated bilirubin
Bilirubin glucuronides = Conjugated bilirubin
Conjugation in liver
Excreted as conjugated bilirubin
Duodenum
20% of urobilinogen formed in the intestine is reabsorbed
Converted to urobilinogen in the intestine
80% excreted
Stercobilinogen
Stercobilin (stool)
Urobilinogen (urine)

FIG. 6.1: Bilirubin metabolism.

- Present in hepatocytes and leak into the blood with liver cell damage.
- **Normal value:** 10–40 U/L.
- Poor correlation between the degree of liver cell damage and level of aminotransferases
- **Aspartate aminotransferase:** Mitochondrial and cytoplasmic isoenzymes. High concentration also in heart, muscle, kidney, and brain. Raised in hepatic necrosis, myocardial infarction, muscle injury, and congestive cardiac failure.
- **Alanine aminotransferase:** Cytosolic enzyme. More specific for liver injury.

AST: ALT ratio:

- AST: ALT >1: Chronic viral hepatitis and nonalcoholic fatty liver disease (NAFLD).
- AST: ALT ratio >2:1 is suggestive, while a ratio >3:1 is highly suggestive of alcoholic liver disease. A low level of ALT in the serum in alcoholic patients is due to an alcohol-induced deficiency of pyridoxal phosphate.

Causes of Elevated Serum Aminotransferases (Tables 6.1A and B)

TABLE 6.1A: Chronic mild elevations (<150 U/L).

ALT > AST		*AST > ALT*	
Hepatic	***Nonhepatic***	***Hepatic***	***Nonhepatic***
➢ α1-antitrypsin deficiency ➢ Autoimmune hepatitis ➢ Chronic viral hepatitis (B, C, D) ➢ Hemochromatosis ➢ Medications and toxins ➢ Steatosis and steatohepatitis	➢ Celiac disease ➢ Hyperthyroidism	➢ Alcohol-related liver injury ➢ Cirrhosis ➢ Wilson's disease	➢ Hypothyroidism ➢ Macro-AST ➢ Myopathy ➢ Strenuous exercise

(ALT: Alanine aminotransferase; AST: Aspartate aminotransferase)

TABLE 6.1B: Acute severe elevations (>1,000 U/L).

ALT > AST		*AST > ALT*	
Hepatic	***Nonhepatic***	***Hepatic***	***Nonhepatic***
➢ Acute bile duct obstruction ➢ Acute Budd–Chiari syndrome ➢ Acute viral hepatitis ➢ Autoimmune hepatitis ➢ Hepatic artery ligation ➢ Ischemic hepatitis ➢ Medications/toxins ➢ Wilson's disease	None	Medications or toxins in a patient with underlying alcoholic liver injury	Acute rhabdomyolysis

(ALT: Alanine aminotransferase; AST: Aspartate aminotransferase)

Enzymes that reflect cholestasis

These include three enzymes: (1) alkaline phosphatase (ALP), (2) 5'-nucleotidase, and (3) ϒ-glutamyl transpeptidase (GGT).

Alkaline phosphatase:

- Many distinct isoenzymes—liver, bone, kidney, placenta, small intestine, origin can be determined by electrophoretic separation.
- **Normal serum level:** 3–13 KA units (80–240 IU/L).
- Raised levels of liver-derived ALP are not totally specific for cholestasis.
- **Low levels:** Wilson's disease, with fulminant hepatitis and hemolysis, possibly because of reduced activity of the enzyme owing to displacement of the cofactor zinc by copper. Ratio of ALP to total bilirubin of <2 is quite specific for Wilson's disease.
- **Raised serum ALP levels:**
  - <2.5 times: Hepatocellular jaundice
  - >4 times:
    - Obstructive jaundice (intrahepatic or extrahepatic obstruction)
    - Infiltrative liver diseases, e.g., cancer, metastases, and amyloidosis
    - Bone lesions with rapid bone turnover, e.g., Paget's disease
    - Primary biliary cirrhosis

ϒ-glutamyl transpeptidase (GGT)

- Microsomal enzyme is present in liver, renal tubules, pancreas, and intestine
- Identify the source of isolated elevation in serum ALP (GGTP is normal in bone disease)
- Screening test for alcoholism: If ALP is normal, raised serum γ-GT is a good guide to alcohol intake of more than 60 g/day. (Detection of alcohol abuse in patients who deny it).
- **Elevated GGT levels:**
  - Biliary obstruction
  - Alcoholism
  - Liver parenchymal damage
  - Nonalcoholic fatty liver
  - Other causes: Chronic obstructive lung disease, diabetes mellitus, hyperthyroidism, obesity, and renal failure.
  - Patients taking phenytoin, barbiturates, and antiretroviral therapy—nonnucleoside reverse transcriptase inhibitors and abacavir.

5'-nucleotidase:

- Microsomal enzyme has similar significance as that of GGT.
- 5'NT levels are not increased in bone disease but are increased in hepatobiliary disease.

Carbohydrate deficient transferrin (CDT)

- The proportion of transferrin with zero, one or two sialic acid chains increases with alcohol consumption but also in the carbohydrate deficient glycoprotein syndrome, leading to the so-called carbohydrate deficient transferrin.
- CDT is a marker of chronic alcohol abuse and current assays can be used in detecting an alcohol consumption of 40–60 g of ethanol per day, consumed for 2–3 weeks or longer

- Some of the uses of CDT include long-term monitoring for early detection of relapse drinking during medical treatment, permitting early intervention.
- Other tests have recently been proposed for detection of alcohol abuse include mitochondrial acetaldehyde adducts, beta-hexosaminidase or phosphatidyl ethanol (PEth).

Lactate dehydrogenase (LDH): Not useful in diagnosis of liver diseases

- Moderate elevations: Ischemic hepatitis and hepatic metastasis.
- ALT/LDH ratio >1.5 suggests ischemic hepatitis while ratio <1.5 is seen with paracetamol toxicity.

Biosynthetic Function of the Liver

Tests that measure synthetic function of the liver.

Plasma Proteins

Serum Albumin

- It is **synthesized exclusively in liver** and used as a marker of synthetic function.
- **Normal serum albumin level:** 4–5.5 g/100 mL and albumin has a half-life of around 20 days.

Significance

- **Low levels:** Serum albumin is an **excellent marker of hepatic synthetic function**. Hypoalbuminemia is observed in chronic liver diseases such as cirrhosis and chronic hepatitis and usually reflects severe liver damage and decreased albumin synthesis. A **falling serum albumin level in liver disease is a bad prognostic sign.**
- **Apart** from chronic liver disease, it may be observed in chronic inflammation, sepsis, expanded plasma volume, and renal or gastrointestinal (GI) loss.

Serum Globulins

- **They** constitute a group of proteins made up of ϒ-globulins (immunoglobulins) synthesized by B lymphocytes and α- and β-globulins synthesized primarily by hepatocytes.
- **Normal serum globulin level:** 1.5–3.5 g/100 mL.
- **Significance:** ϒ-globulins are **increased in chronic liver disease** (e.g., chronic hepatitis and cirrhosis). Increase in the concentration of specific isotypes of ϒ-globulins (immunoglobulins) is helpful in the recognition of certain chronic liver diseases (**Table 6.2**).
- **Cirrhosis:** Plasma proteins show decrease in albumin and increase in ϒ-globulin.

TABLE 6.2: Specific types of elevated immunoglobulin and its associated conditions.

Specific type of immunoglobulin	*Condition in which it is raised*
IgG	Chronic hepatitis, autoimmune hepatitis (AIH), and cryptogenic cirrhosis
IgA	Alcoholic liver disease
IgM	Primary biliary cholangitis

Coagulation Factors

- **Liver produces all the coagulation factors, except factor VIII.**
- Vitamin K is required for the activation of coagulation **factors II, VII, IX, and X.**
- The coagulation factors have short half-life time. Thus, measurement of the clotting factors is the **single best measure of hepatic synthetic function** and useful in both the diagnosis and assessing the prognosis of acute parenchymal liver disease.
- **Prothrombin time:**
  - Prothrombin time depends on factors I, II, V, VII, and X.
  - Normal value is 11–12.5 seconds.
  - Prothrombin time collectively measures factors II, V, VII, and X.
  - Causes of prolonged prothrombin time are listed in **Box 6.2**.

Box 6.2: Causes of prolonged prothrombin time.

- Severe liver damage: Acute hepatitis (e.g., viral hepatitis), cirrhosis
- Deficiency of vitamin K
  - Obstructive jaundice that reduces vitamin K absorption
  - Fat malabsorption
  - Poor intake
  - Antibiotic therapy which produces destruction of vitamin
  - Producing commensals
- Disseminated intravascular coagulation
- Drugs and toxins: Warfarin, rivaroxaban, apixaban, edoxaban, dabigatran, viper envenomation, anticoagulant rodenticide poisoning

- *Unlike the serum albumin, the prothrombin time allows an assessment of current hepatic synthetic function; factor VII has the shortest serum half-life (6 hours) of all the clotting factors.*

Ceruloplasmin

- It is an **acute-phase reactant** synthesized by the liver.
- In blood, it binds to copper and acts as a major carrier for copper.
- **Normal plasma level:** 20–60 mg/dL
- **Causes of elevated levels:** Infections, liver diseases, obstructive jaundice, rheumatoid arthritis, and pregnancy.
- **Causes of decreased levels:** Wilson's disease (due to decreased rate of synthesis), neonates, Menkes disease, kwashiorkor, marasmus, protein-losing enteropathy, and copper deficiency.

Cholesterol

It is synthesized in the liver. Advanced liver disease may be associated with very low cholesterol. However, primary biliary cholangitis (PBC) may be associated with markedly raised cholesterol. Similarly, a low urea level also indicates severe liver dysfunction.

Liver functions tests and their significance are summarized in **Table 6.3**.

TABLE 6.3: Summary of main liver function tests and its significance.

Test	*Function determined/assessed*
Serum bilirubin	Transport
Serum enzymes	
➤ Serum aminotransferases (ALT and AST)	➤ Hepatocellular damage
➤ Serum alkaline phosphatase (ALP)	➤ Biliary tract obstruction
➤ ϒ-glutamyl transpeptidase (GGT)	➤ Enzyme induction
Plasma proteins	Synthesis
Prothrombin time	Synthesis

(ALT: Alanine aminotransferase; AST: Aspartate aminotransferase)

Serum Autoantibodies

Antimitochondrial antibody (AMA): *Antinuclear, smooth muscle (actin), liver/kidney microsomal antibodies, antinuclear cytoplasmic antibodies (ANCA).*

Urine Tests

Bilirubin in Urine

- Normally, bilirubin cannot be detected in urine.
- In unconjugated hyperbilirubinemia, urine does not contain bilirubin **(acholuric jaundice)**. Thus, **absence of bilirubin in urine in a jaundiced patient suggests unconjugated hyperbilirubinemia**.
- In conjugated hyperbilirubinemia, urine contains bilirubin. Thus, **bilirubinuria in a jaundiced patient points to conjugated hyperbilirubinemia** (hepatobiliary disease).
- Urinary bilirubin is detected by Fouchet's test.

Urine Urobilinogen

- Urobilinogen is **normally present in urine in trace amounts** (1–2 mg/dL) and is insufficient to cause a significant positive reaction.
- **Causes of increased urobilinogen in urine (Box 6.3).**
- **Causes of absent urobilinogen:** In **obstructive jaundice** (bilirubinuria present), bilirubin does not reach the intestine and so is not converted into urobilinogen.
- Urinary urobilinogen is detected by Ehrlich's aldehyde test.

Box 6.3: Causes of increased urobilinogen in urine.

Hemolytic anemias (without bilirubin in urine)
- Thalassemia
- Sickle-cell anemia
- Hereditary spherocytosis

Liver diseases (bilirubinuria present)
- Preicteric phase of infective hepatitis
- Drugs or toxic hepatitis
- Cirrhosis

α-Fetoprotein (AFP)

- α-fetoprotein is normally produced by fetal liver cells and its levels falls to low levels after birth.
- **Causes of elevated levels** of α-fetoprotein are:
  - **Hepatocellular carcinoma (HCC)**
  - **Carcinomas of stomach, pancreas, gallbladder, bile ducts, and lungs**
  - **Teratomas**

DIAGNOSTIC PROCEDURES

Endoscopic Retrograde Cholangiopancreatography

Q. IM5.13 Enumerate the indications for ultrasound and other imaging studies including MRCP and ERCP and describe the findings in liver disease.

Endoscopic retrograde cholangiopancreatography (ERCP) is a technique used to **outline the biliary and pancreatic ducts**.

Procedure

An endoscope is passed into the second part of the duodenum and cannulation of the ampulla. Contrast is injected into the biliary tree and the patient is screened radiologically. **Figure 6.2** shows ERCP with stone in the common bile duct (CBD).

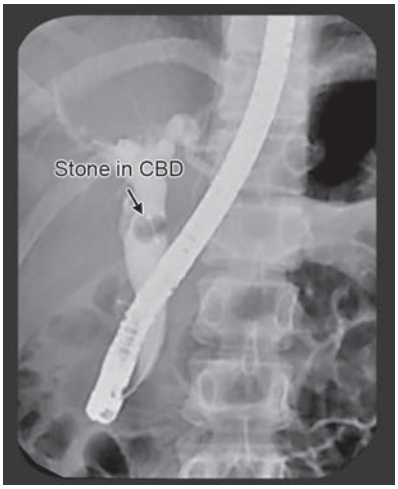

FIG. 6.2: ERCP shows stone in the common bile duct (CBD).

Uses of ERCP (Table 6.4)

TABLE 6.4: Uses of ERCP.

Diagnostic procedure	***Therapeutic procedure***
Evaluation of acute/chronic pancreatitis	Removal of CBD stones
Evaluation of patient with obstructive jaundice	Sphincterotomy
Cholangitis	Dilatation of benign strictures
Biopsy for periampullary carcinoma	Placement of nasobiliary catheters and biliary stents
	Brachytherapy for cholangiocarcinoma

(ERCP: cholangiopancreatography; CBD: common bile duct)

Complications

The complication rate in diagnostic ERCP is 2–3%. Complications include pancreatitis, cholangitis, bleeding, and duodenal perforation.

Magnetic Resonance Cholangiopancreatography

Q. **Write a short note on magnetic resonance cholangiopancreatography.**

Magnetic resonance cholangiopancreatography (MRCP) is a noninvasive technique largely replacing diagnostic (but not therapeutic) ERCP.

Technique

A heavily T2-weighted sequence enhances visualization of the water-filled biliary (intrahepatic ducts) and pancreatic ducts (extrahepatic ducts). It produces high-quality images of ductal anatomy.

Advantages of MRCP over ERCP

See **Box 6.4.**

Box 6.4: Advantages of MRCP over ERCP.

- No need for contrast media or ionizing radiation
- Images can be acquired faster
- Less operator dependent
- No risk of pancreatitis

Indications

- Diagnosis of bile duct obstruction and pancreatic duct abnormalities, e.g., choledocholithiasis, malignant obstruction of bile and pancreatic ducts, congenital anomalies, and chronic pancreatitis.
- Unsuccessful ERCP or a contraindication to ERCP (as in patients with cardiorespiratory compromise, renal failure).

Endoscopic Ultrasound

Q. **Write a short note on endoscopic ultrasound.**

Procedure

In endoscopic ultrasound (EUS), a small high-frequency ultrasound probe is placed on the tip of an endoscope and placed by direct vision into the duodenum.

Advantages

Gradually replacing diagnostic ERCP:

- Close proximity of the ultrasound probe to the pancreas and biliary tree allows high-resolution ultrasound imaging.
- Accurate staging of small, potentially operable, pancreatic tumors (e.g., neuroendocrine tumors) can be done.
- It is less invasive method for bile duct imaging.

Uses

Diagnostic

- Imaging pancreatic and biliary diseases, e.g., choledocholithiasis, pancreatic and biliary cancers, and cystic lesions of the pancreas
- Ampullary carcinoma: To know the local extension of tumor and regional lymph node metastasis that cannot be evaluated by ERCP
- Performing fine-needle aspiration under EUS guidance from suspicious lesions for confirmation of malignancy.

Therapeutic

Increasingly used for guided interventions:

- To reduce pain in patients with unresectable pancreatic carcinoma, for injecting bupivacaine and alcohol into the celiac ganglia.
- Endoscopic management of pancreatic pseudocysts.

Disadvantages

- Cost is high.
- High degree of training is required.

Liver Biopsy

Q. Write a short note on the indications, significance, and complications of liver biopsy.

Percutaneous liver biopsy is an invasive procedure that can be performed with or without radiographic guidance.

Indications, contraindications, and complications of liver biopsy (Table 6.5).

TABLE 6.5: Indications, contraindications, and complications of liver biopsy.

Indications	*Contraindications*	*Complications*
➢ Cirrhosis of liver ➢ Unexplained hepatomegaly, splenomegaly, jaundice ➢ Hepatitis: Chronic or acute ➢ Tumors: Primary or secondary ➢ Granulomatous diseases: Tuberculosis, leprosy, sarcoidosis ➢ Storage and metabolic disorders: amyloidosis, storage disorders, hemochromatosis, Wilson's disease ➢ After liver transplantation: Assess for rejection, disease recurrence ➢ Brucellosis ➢ Pyrexia of unknown origin (with hepatomegaly) ➢ Malignancy ➢ Miliary tuberculosis ➢ Lymphoma staging	➢ Hepatocellular failure ➢ Congenital coagulation disorders ➢ Hepatobiliary infections ➢ Massive ascites ➢ Obstructive jaundice ➢ Severe jaundice ➢ Prolonged prothrombin time: More than 3 seconds over control ➢ Relative contradictions: – Hydatid cyst liver – Hemangioma liver	➢ Pleurisy, perihepatitis ➢ Hemorrhage ➢ Intrahepatic hematoma ➢ Biliary peritonitis ➢ Hemobilia ➢ Arteriovenous fistula ➢ Infection ➢ Organ perforation ➢ Carcinoid crisis

JAUNDICE

Q. List the causes of jaundice. How will you arrive at the etiology of jaundice? Give the points of differentiation in clinical features and investigations.

Q. IM5.1 Describe and discuss the physiologic and biochemical basis of hyperbilirubinemia.

Definition

Jaundice (icterus) is defined as **yellowish pigmentation** of **skin, mucus membranes, and sclera** due to **increased levels of bilirubin** in the blood. The scleral involvement is because of its rich elastic tissue that has special affinity for bilirubin.

- **Normal serum bilirubin level:** In normal adults, it ranges from 0.3 to 1.2 mg/dL.
- **Jaundice** is clinically detected when the **serum bilirubin level is above 2.0–2.5 mg/dL**. With severe disease, the levels may be as high as 30–40 mg/dL.
- **Latent jaundice** is the term used when serum bilirubin is more than 1.2 mg/dL but less than 2.5 mg/dL.

- *Carotenemia is characterized by yellowish pigmentation of skin by carotene but not of sclera. Quinacrine consumption also causes yellowish discoloration of skin and mucus membranes.*

Classification of Jaundice

Q. Write short note on causes of indirect/unconjugated hyperbilirubinemia.

Jaundice can be classified in two ways:

1. **Based on the underlying cause (Table 6.6):**
   - Predominantly unconjugated hyperbilirubinemia
   - Predominantly conjugated hyperbilirubinemia.

TABLE 6.6: Classification of jaundice.

Predominantly unconjugated hyperbilirubinemia	***Predominantly conjugated hyperbilirubinemia***
Increased production of bilirubin	**Decreased hepatocellular excretion**
Hemolytic anemias	Liver damage or toxicity (e.g., hepatitis)
Resorption internal hemorrhage (e.g., GI bleeding, hematomas)	Deficiency of membrane transporters—Dubin–Johnson syndrome, Rotor syndrome
Ineffective erythropoiesis	
Reduced hepatic uptake	**Impaired intra/extrahepatic bile flow**
Drug that interference with membrane carrier systems	Inflammatory destruction of bile ducts (e.g., primary biliary cirrhosis)
Diffuse liver disease (hepatitis, cirrhosis)	Gallstones
Some cases of Gilbert syndrome	Carcinoma: Head of pancreas, periampullary carcinoma, cholangiocarcinoma
Impaired bilirubin conjugation	
Physiologic jaundice of the newborn	
Crigler–Najjar syndrome types I and II	
Gilbert syndrome	
Diffuse liver disease (hepatitis, cirrhosis)	

2. **Based on pathological mechanism (Table 6.7):**
   - Hemolytic (prehepatic) jaundice
   - Hepatocellular jaundice (hepatic)
   - Obstructive jaundice (posthepatic).

TABLE 6.7: Classification of jaundice based on the pathological mechanism.

Hemolytic jaundice	
Intracorpuscular defects	**Extracorpuscular defects**
➢ Hereditary: Spherocytosis, sickle cell disease, thalassemia, G6PD deficiency ➢ Acquired: Vitamin B_{12} and folate deficiency	➢ Autoimmune, alloimmune hemolytic anemias ➢ Fragmentation syndromes: Prosthetic valves ➢ Drugs, e.g., sulfasalazine, dapsone ➢ Infections of RBCs: Malaria
Hepatocellular jaundice	
➢ Viral, alcoholic hepatitis ➢ Chronic hepatitis ➢ Cirrhosis—any type ➢ Infiltrations	➢ Ischemic liver ➢ Drug-induced hepatitis: Chlorpromazine, imipramine, INH, rifampicin, erythromycin, amitriptyline, halothane, methyldopa
Cholestatic (obstructive) jaundice	
Intrahepatic (small duct obstruction)	**Extrahepatic (large duct obstruction)**
➢ Primary biliary cirrhosis ➢ Primary sclerosing cholangitis ➢ Alcohol, drugs ➢ Viral hepatitis ➢ Cirrhosis ➢ Chronic hepatitis ➢ Secondaries in liver ➢ Severe bacterial infections ➢ Inherited cholestatic liver disease ➢ Pregnancy	➢ Gallstones in the common bile duct (CBD) ➢ Parasitic: Helminths in the CBD ➢ Carcinoma – Head of pancreas – Ampulla of Vater – Bile duct (cholangiocarcinoma) ➢ Liver metastases ➢ Stricture of bile ducts ➢ Sclerosing cholangitis ➢ Chronic pancreatitis

Q. How do you clinically differentiate hemolytic jaundice, hepatocellular jaundice, and obstructive (cholestatic) jaundice?

Hemolytic Jaundice

- **Increased destruction of red blood cells or their precursors** causes increased production of bilirubin.
- **Unconjugated bilirubin** accumulates in the plasma and results in jaundice.
- **Jaundice is usually mild (Fig. 6.3)** because normal liver can easily handle the increased bilirubin production.

Clinical features

- **Pallor** due to anemia
- **Mild jaundice** without any signs of liver disease
- **Hepatosplenomegaly** due to increased activity of reticuloendothelial system.
- Gallstones and leg ulcers may be seen depending on the cause of anemia.
- **Dark stools** due to increased stercobilinogen in stool
- **Urine turns dark yellow** on standing. This is due to increased urobilinogen being converted to urobilin in urine.

Investigations

- Peripheral smear—shows features of hemolysis
- **Predominantly unconjugated hyperbilirubinemia.** Serum bilirubin is raised (<6 mg%).
- **No bilirubin in urine**, because the unconjugated bilirubin is not water soluble and cannot pass into the urine; hence the term "**acholuric jaundice".**
- **Urinary urobilinogen is increased** (more than 4 mg/24 hours).
- Other LFTs (e.g., serum ALP, transferases, and albumin) are normal; however, LDH is increased.

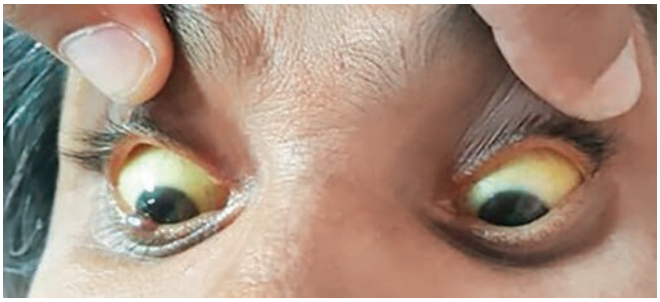

FIG. 6.3: Conjunctiva showing mild jaundice in hemolytic anemia.

Hepatocellular Jaundice

- Hepatocellular jaundice occurs as a **consequence of parenchymal liver disease** which leads to an inability of the liver to transport bilirubin across the hepatocyte into the bile.
- Defect in bilirubin transport across the hepatocyte may occur at any point between the uptake of unconjugated bilirubin into the hepatocyte and transport of conjugated bilirubin into biliary canaliculi.
- In hepatocellular jaundice **(Fig. 6.4)**, **both unconjugated and conjugated bilirubin level rise** in the blood.

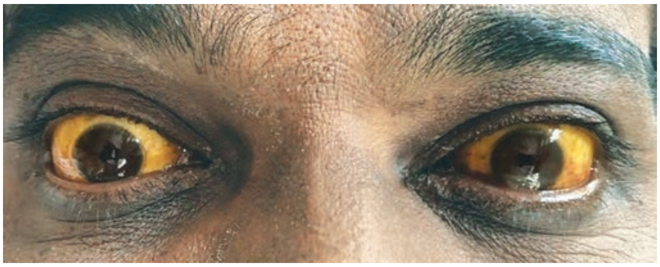

FIG. 6.4: Deep jaundice in viral hepatitis.

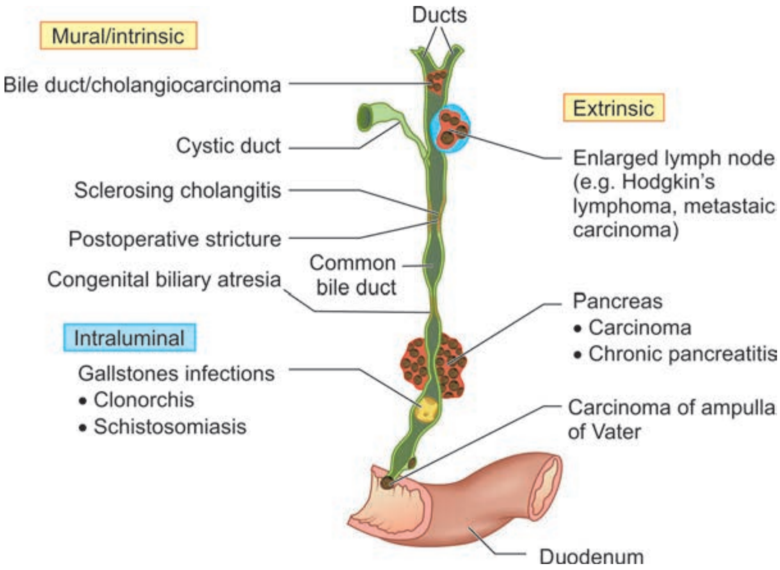
Investigations

- **Raised transaminases** (AST and ALT): Acute jaundice with AST >1,000 U/L is highly suggestive of an **infectious cause** (e.g., hepatitis A, B), **drugs** (e.g., paracetamol) or **hepatic ischemia.**
- Imaging
- Liver biopsy

Cholestatic (Obstructive/Surgical) Jaundice

Q. Write short note on causes and features of obstructive jaundice.

- **Cholestasis means failure of bile flow**. Its cause may be anywhere between hepatocyte and duodenum (**Fig. 6.5**).



Ducts
Mural/intrinsic
Bile duct/cholangiocarcinoma
Cystic duct
Sclerosing cholangitis
Postoperative stricture
Congenital biliary atresia
Common bile duct
Intraluminal
Gallstones infections
• Clonorchis
• Schistosomiasis
Extrinsic
Enlarged lymph node (e.g. Hodgkin's lymphoma, metastaic carcinoma)
Pancreas
• Carcinoma
• Chronic pancreatitis
Carcinoma of ampulla of Vater
Duodenum

FIG. 6.5: Causes of obstructive jaundice.

- Cholestatic jaundice is usually a "**surgical jaundice**" meaning a cause that requires surgical intervention.
- Cholestasis can be intrahepatic or extrahepatic.
- **Consequences of cholestasis:**
  - **Retention of bile acids and bilirubin** in the liver and blood
  - **Deficiency of bile acids in the intestine**

Clinical features (Table 6.8)

TABLE 6.8: Symptoms and signs of cholestatic jaundice.

Symptoms	*Signs*
➢ Jaundice (gradually progressive/fluctuating) ➢ Pruritus ➢ Pale, clay-colored stools ➢ Dark urine (increased conjugated bilirubin)	➢ Deep jaundice with a greenish hue ➢ Scratch marks ➢ Xanthelasmas on eyelids and xanthomas over tendons
Depending on the cause ➢ Fever with chills and rigors (cholangitis) ➢ Weight loss (malabsorption) ➢ Bleeding tendency (vitamin K deficiency) ➢ Bone pains (calcium and vitamin D deficiency) ➢ Abdominal pain (gallstones)	**Depending on the cause** ➢ Palpable gallbladder in carcinoma head of pancreas ➢ Large hard irregular liver (malignancy) ➢ Late features: Secondary biliary cirrhosis and signs of liver cell failure

Investigations

Serum Findings

- **Serum bilirubin is markedly raised** and is predominantly conjugated hyperbilirubinemia
- **Serum ALP is markedly raised** (3–4 times that of normal).
- Minimal biochemical changes of liver parenchymal damage.
- Antimitochondrial antibody (in primary biliary cholangitis).

Urine Findings

- Bilirubin present
- Urobilinogen absent

Clinical features useful in differentiating different types of jaundice are listed in **Table 6.9**.

TABLE 6.9: Clinical features useful in differentiating different types of jaundice.

Feature	*Hemolytic (prehepatic)*	*Hepatocellular (intrahepatic)*	*Obstructive (posthepatic)*
Jaundice Color Depth	Lemon yellow—mild	Orange yellow—variable	Greenish yellow—deep
Pruritus	-	Variable	+
Bleeding tendency	-	+	+ (late)
Anemia	+	-	-
Splenomegaly	+	Variable	Absent (may develop later when cirrhosis develops)
Palpable gallbladder	-	-	May be present
Features of hepatocellular failure	-	+ (early)	+ (late)
Conjugated bilirubin	Absent	Raised	Raised
AST or ALT	Normal	Increased	Normal
ALP	Normal	Normal	Raised
Urine bilirubin	Absent	Present	Present
Urine urobilinogen	Present	Present	Absent

(AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; ALP: Alkaline phosphatase)

Congenital Nonhemolytic Hyperbilirubinemias

Q. List congenital nonhemolytic hyperbilirubinemias.

Various congenital nonhemolytic hyperbilirubinemias are listed in **Table 6.10**.

TABLE 6.10: Congenital nonhemolytic hyperbilirubinemias.

Hereditary disorder	*Mode of inheritance*	*Defects in bilirubin metabolism*	*Characteristics*
Unconjugated hyperbilirubinemia			
Crigler–Najjar syndrome type I	Autosomal recessive	Absent UGT1A1 activity	Fatal
Crigler–Najjar syndrome type II	Autosomal dominant/Autosomal recessive	Decreased UGT1A1 activity	Usually mild
Gilbert syndrome	Autosomal recessive	Decreased UGT1A1 activity	Harmless
Conjugated hyperbilirubinemia			
Dubin–Johnson syndrome	Autosomal recessive	Impaired biliary excretion of bilirubin glucuronides	Liver with pigmented granules in cytoplasm. Harmless
Rotor syndrome	Autosomal recessive	Decreased hepatic uptake Decreased biliary excretion	Harmless

(UGT: uridine diphosphate-glucuronyl transferase)
Individuals with Crigler–Najjar or Gilbert syndrome cannot ConjuGate bilirubin.
Individuals with Rotor syndrome or Dubin–Johnson syndrome cannot get RiD of DiRect bilirubin.

Gilbert Syndrome

- Relatively **common,** autosomal **recessive, harmless,** inherited disorder
- **Etiology: Mutations in *UGT1* gene—**inadequate synthesis of UGT1A1 enzyme (about 30% of normal)
- **Clinical features:**
  - More common in males
  - Usually asymptomatic, jaundice is incidentally detected.
  - **Mild, chronic unconjugated fluctuating hyperbilirubinemia.**
  - No other functional derangements
  - Severity of jaundice increases with infections, fatigue, exertion, and fasting
  - Physical examination is otherwise normal.
- **Investigations:**
  - Unconjugated hyperbilirubinemia (<6 mg%)—raised bilirubin levels during fasting is the most common diagnostic tool.
  - Urine: Increased urobilinogen and absent bilirubinuria
  - Peripheral smear, reticulocyte count, and serum haptoglobin: Normal

Treatment: Usually no treatment is required. Glucuronosyltransferase activity may be increased by administering phenobarbital 60 mg BD.

Crigler–Najjar Syndrome Type I

- Rare, **autosomal recessive** disorder, invariably fatal
- **Etiology:** Due to **complete absence of hepatic UGT1A1**.
- Chronic, severe, **unconjugated hyperbilirubinemia** with severe jaundice, icterus and **death** secondary to kernicterus **within 18 months** of birth.
- **Bile** does contain conjugated bilirubin; hence it is **colorless**.
- **Liver** is **morphologically normal** by light and electron microscopy.

Treatment: Daily phototherapy and **liver transplantation.** Phenobarbital has **no effect**.

Crigler–Najjar Syndrome Type II

- Less severe, nonfatal disorder, also known as **Arias syndrome**
- Autosomal recessive inheritance in most cases
- Partial deficiency of UGT1A1 enzyme (10% of normal).
- Jaundice is milder than type I and does not develop kernicterus

Treatment: Treatment includes ultraviolet light therapy and liver transplantation. Phenobarbital treatment can improve bilirubin glucuronidation by inducing hypertrophy of hepatocellular endoplasmic reticulum.

Dubin–Johnson Syndrome

- Benign autosomal recessive disorder
- **Etiology: Complete absence** of the **multidrug resistance protein 2 (MRP2)** which is required for secretion of conjugated bilirubin from hepatocytes into canaliculi. This leads to defect in hepatocellular excretion of bilirubin glucuronides across biliary canalicular membrane.
- **Clinical features:** Chronic, recurrent conjugated hyperbilirubinemia, generally after puberty.

- **Investigations:**
  - Conjugated hyperbilirubinemia (usually 2–5 mg/dL)
  - Bromosulfthalein (BSP) clearance—impaired with reflux into blood at 90 minutes
  - Bilirubinuria
  - Gallbladder is usually not visualized on oral cholecystography.
  - Liver biopsy: **Dark pigment** in centrilobular hepatocytes, **coarse melanin-like pigmented granules** within the enlarged lysosomes, present in the cytoplasm. Pigment composed of polymers of epinephrine metabolites.

No treatment is required in most cases. Most of the patients have a normal life expectancy.

Rotor Syndrome

- Rare, autosomal recessive, asymptomatic conjugated hyperbilirubinemia.
- Defective organic anion transport proteins (OATP), 1B1 and 1B3 in hepatocytes → impaired transport and reduced storage capacity of conjugated bilirubin
- Clinical presentation—mild jaundice.
- ***Investigations***:
  - Conjugated hyperbilirubinemia
  - Bilirubinuria
  - BSP clearance test—impaired without reflux back into blood
  - Gallbladder is visualized on oral cholecystography.
- Liver is morphologically normal. No pigmentation

TYPES OF SYNDROME

Parameter	***Gilbert's***	***Crigler-Najjar type I***	***Crigler-Najjar type II***	***Dubin-Johnson***	***Rotor's***
Incidence	6%–12%	Very rare	Uncommon	Uncommon	Rare
Gene affected	*UGT1A1*	*UGT1A1*	*UGT1A1*	*MRP2*	Unknown
Metabolic defect	↓ Bilirubin conjugation	No bilirubin conjugation	↓↓ Bilirubin conjugation	Impaired canalicular export of conjugated bilirubin	Impaired canalicular export of conjugated bilirubin
Plasma bilirubin (mg/dL)	≤3 in absence of fasting or hemolysis, almost all unconjugated	Usually >20 (range, 17–50), all unconjugated	Usually <20 (range, 6–45), almost all unconjugated	Usually <7, about half conjugated	Usually <7, about half conjugated
Liver histology	Usually normal, occasional ↑ lipofuscin	Normal	Normal	Coarse pigment in centrilobular hepatocytes	Normal
Other distinguishing features	↓ Bilirubin concentration with phenobarbital	No response to phenobarbital	↓ Bilirubin concentration with phenobarbital	↑ Bilirubin concentration with estrogens; ↑↑ urinary coproporphyrin I/III ratio; slow BSP elimination kinetics with secondary rise	Mild ↑ urinary coproporphyrin I/III ratio; very slow BSP* elimination kinetics without secondary rise
Prognosis	Normal	Death in infancy if untreated	Usually normal	Normal	Normal
Treatment	None	Phototherapy as a bridge to liver transplantation	Phenobarbital for ↑↑ bilirubin concentration	Avoid estrogens	None available

*No longer available.

(BSP: Bromsulphthalein; MRP2: Multidrug resistance-associated protein 2; UGT1A1: UDP-glucuronosyltransferase)

Benign Recurrent Intrahepatic Cholestasis (BRIC)

It is a rare, autosomal recessive disorder characterized by recurrent, self-limited episodes of cholestasis manifested by pruritus, anorexia, fatigue, steatorrhea, and jaundice. This is due to mutations in both alleles of ATP8B1 (BRIC1) or ABCB11 (BRIC2) which cause cholestasis by impairing the function of the bile salt export pump (BSEP), which actively transports bile into canaliculi. **Laboratory findings** during episodes reveal an elevated total bilirubin, which is predominantly direct, alkaline phosphatase is always elevated markedly while transaminases are normal or mildly elevated. The hallmark of BRIC is that the GGT is normal or only mildly elevated in comparison with the other causes of intrahepatic cholestasis.

Treatment is mainly supportive, aimed at relieving symptoms, shortening the episodes, and preventing complications.

Progressive Familial Intrahepatic Cholestasis (PFIC)

It is a group of autosomal recessive cholestatic liver diseases which are subgrouped according to the genetic defect, clinical presentation, laboratory findings and liver histology. Progressive liver fibrosis, cirrhosis, and end-stage liver disease (ESLD) may eventually develop.

The disease has been classified into three subgroups. All the three types of PFIC are caused by defects in bile secretion from hepatocyte to canaliculi. In PFIC-1 and PFIC-2, bile acid secretion is depleted, while in PFIC-3, bile phospholipid secretion is impaired.

PFIC-1 patients may also present with short height, growth retardation, deafness, diarrhea, pancreatitis, increased sweat electrolyte concentration, hepatic steatosis and epistaxis despite bleeding diathesis. while PFIC-2 may directly refer with a malignancy. PFIC-3 patients are likely to present with cirrhosis in late childhood and young adulthood.

Charcot's Triad

Q. Write a short note on Charcot's triad.

It consists of following in the presence of stones in bile ducts:

- Pain in the right hypochondrium
- Intermittent or persistent jaundice
- Fever with chills and rigors due to acute cholangitis

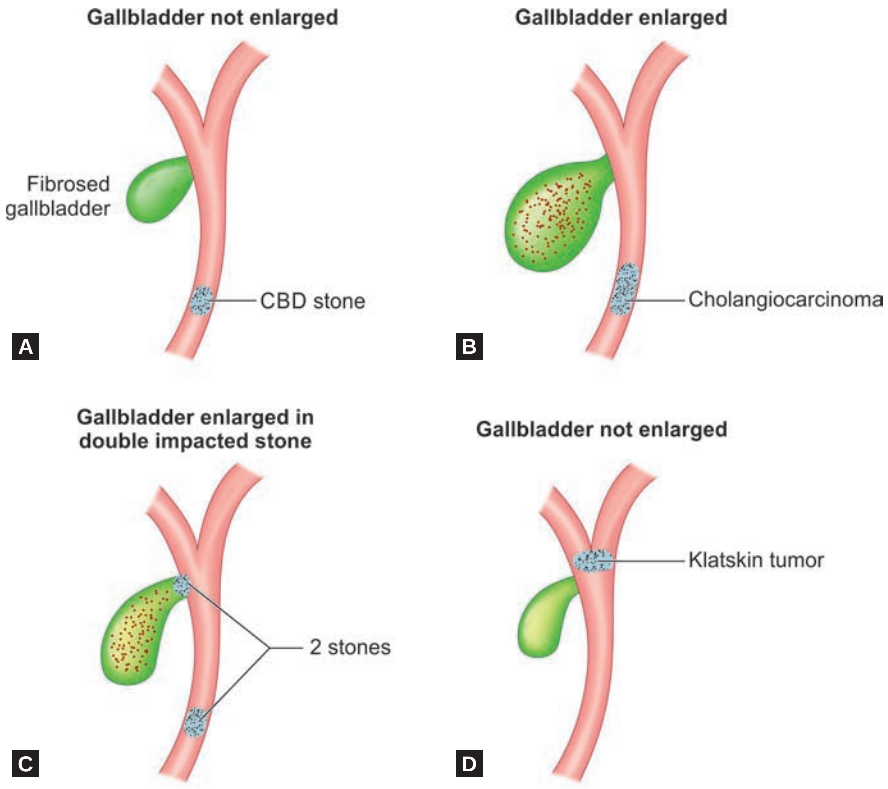
Reynolds' pentad adds mental status changes and sepsis to the triad.

Courvoisier's Law or Courvoisier-Terrier Sign (Figs. 6.6A to D)

Q. Describe Courvoisier's law.

In obstruction of CBD due to a stone, the gallbladder as a rule is impalpable (no distension). This is because the gallbladder is usually already shriveled, fibrotic, and nondistensible and hence will not be palpable.

In obstruction from other causes (e.g., carcinoma head of pancreas) distension of the gallbladder is common and hence gallbladder may be palpable.



Gallbladder not enlarged
Fibrosed gallbladder
CBD stone
A
Gallbladder enlarged
Cholangiocarcinoma
B
Gallbladder enlarged in double impacted stone
2 stones
C
Gallbladder not enlarged
Klatskin tumor
D

FIGS. 6.6A TO D: (A and B) Courvoisier's law; (C and D) Exceptions to Courvoisier's law.

Exceptions of Courvoisier's law

- Double impaction: Stones, simultaneously occluding the cystic duct and the distal.
- Pancreatic calculus obstructing the ampulla of Vater
- Oriental cholangiohepatitis
- Klatskin tumor with carinal obstruction leaving the gall bladder not distended.
- Periampullary carcinoma in patients with cholecystectomy
- Mirizzi syndrome
- Gallbladder situated beneath the liver in an obese patient may not be palpable.

VIRAL HEPATITIS

Q. IM5.4 **Describe and discuss the epidemiology, microbiology, immunology and clinical evolution of infective (viral) hepatitis.**

Q. **Write a short note on the diagnosis, prevention, and management of acute viral hepatitis.**

Etiology

Q. **List the viruses causing acute hepatitis.**

Various causes of acute hepatitis and types and causes of viral hepatitis are listed in **Box 6.5** and **Table 6.11**, respectively.

TABLE 6.11: Types of viral hepatitis.

Hepatitis caused by common (hepatotropic) viruses		
Type of hepatitis	**Causative agent**	***Other viruses***
Hepatitis A	Hepatitis A virus (HAV)	➢ Cytomegalovirus ➢ Epstein–Barr virus ➢ Herpes simplex virus ➢ Yellow fever virus ➢ Hepatitis G virus ➢ Dengue virus
Hepatitis B	Hepatitis B virus (HBV)	
Hepatitis C	Hepatitis C virus (HCV)	
Delta hepatitis	Hepatitis D virus (HDV)	
Hepatitis E	Hepatitis E virus (HEV)	

Box 6.5: Causes of acute hepatitis.

- Viral hepatitis **(Table 6.11)**
- Other infections: Leptospirosis, malaria, dengue, brucellosis
- Alcohol
- Drugs: Paracetamol, isoniazid (INH), rifampicin, halothane
- Ischemic and vascular:
  - Cardiogenic shock
  - Hypotension
  - Cocaine, methamphetamine, and ephedrine
  - Acute Budd–Chiari syndrome
- Toxins: Amanita, carbon tetrachloride, and yellow phosphorous
- Pregnancy-related:
  - Preeclampsia
  - Acute fatty liver of pregnancy
  - HELLP syndrome
- Immunological: Autoimmune hepatitis, primary sclerosing cholangitis
- Metabolic or hereditary:
  - Nonalcoholic fatty liver disease
  - Hemochromatosis
  - Wilson's disease

Hepatitis A

Q. **Discuss the clinical features, investigations, and management of hepatitis A infection.**

Etiology

- Caused by hepatitis A virus (HAV) which is a nonenveloped, 27-nm, **RNA virus** belonging to the Picornavirus group.
- Hepatitis A is the **most common type of viral hepatitis,** often occurs in epidemics.
- It most commonly affects children and young adults.
- **Overcrowding and poor sanitation** facilitate the spread.

Source of Infection

The only source of infection is **acutely infected person.**

Virus replicates in the liver, is excreted in bile and then excreted in stool/feces of infected persons for about 2 weeks before the onset of symptoms and then for a further 2 weeks or so.

Mode of Spread

Fecal-oral route (either via person-to-person contact or consumption of contaminated food or water). In outbreaks, it spreads through water, milk, and shellfish.

Incubation Period

- **15–45 days** (average 28 days).
- There is no carrier state.
- Clinical features are discussed together.

Extrahepatic Manifestations

Extrahepatic manifestations are less frequent in acute HAV infection than in acute hepatitis B virus (HBV) infection. Most common manifestations are quickly fading rash (14%) and arthralgias (11%) while uncommon are myocarditis, thrombocytopenia, aplastic anemia, red cell aplasia, leukocytoclastic vasculitis, glomerulonephritis, and arthritis, in which immune-complex disease is believed to play a pathogenic role.

Prevention and Prophylaxis

- Maintain good hygiene and improve social conditions. HAV is resistant to chlorination but is killed by boiling water for 10 minutes.
- **Active immunization:** A formaldehyde-inactivated HAV vaccine (contains the single HAV antigen) for active immunization and can be used in individuals above the age of 2 years. It probably provides lifelong immunity.
- **Passive immunization:** Normal human immunoglobulin [0.02 mL/kg intramuscularly (IM)] made from pooled human plasma is used if exposure to HAV is <2 weeks and can protect from HAV infection for 3 months. HAV vaccine should also be administered.

Hepatitis B

Q. Discuss the clinical features, complications and management of hepatitis B infection.

Etiology

Hepatitis B is caused by HBV which is a **hepatotropic DNA virus** belonging to the family Hepadnaviridae.

Structure and Genome of HBV

Complete infective virion (HBV virion) is called Dane particle. It is spherical 42-nm particle and **double-layered** comprising an inner core or nucleocapsid (27 nm) surrounded by an outer envelope of surface protein (HBsAg).

Viral genome: It consists of partially double-stranded circular DNA and has four genes.

1. **Hepatitis B surface antigen (HBsAg) (*S* gene): HBsAg** is a product of *S* gene which is secreted into the blood in large amounts. HBsAg is immunogenic.
2. **Hepatitis B core antigen (HBcAg) (*C* gene):** The *C* gene produces two antigenically different products:
   i. **Hepatitis B core antigen (HBcAg):** It remains intracellular within the hepatocytes and does not circulate in the serum. Hence, it is not detectable in the serum of patients.
   ii. Hepatitis B e antigen **(HBeAg):** It is secreted into serum and is a **surrogate (substitute) marker for high levels of viral replication**. It is essential for the establishment of persistent infection.
3. **HBV polymerase (*P* gene): A polymerase (Pol**) is a product of *P* gene and DNA polymerase enzyme is needed for virus replication.
4. **HBxAg (*X* gene): HBx protein** is necessary for virus infectivity and has been **implicated in the pathogenesis of liver cancer** in HBV infection.

Source of infection: Human suffering from hepatitis (acute/chronic) or carriers is the only source of infection. HBV is 100 times as infectious as human immunodeficiency virus (HIV) and 10 times as infectious as hepatitis C virus (HCV).

Mode of Transmission

Q. Write a short note on mode of transmission of hepatitis B (serum hepatitis).

- **Vertical/congenital transmission:** Transmission from mother [who is carrier for HBV (90% HBeAg+ve, 30% HBeAg–ve)] to child may occur in utero, during parturition, or soon after birth. It is not transmitted by breastfeeding.
- **Horizontal transmission:** It is the **dominant mode** of transmission.
  - **Parenteral:** It is the major route of transmission but occasionally nonparenteral.
    - By **percutaneous and mucus membrane** exposure to infectious body fluids, through minor cuts/abrasions in the skin or mucus membranes. In children, it can be transmitted through minor abrasions or close contact with other children. HBV can survive for long periods on household articles, e.g., toys, toothbrushes, and may transmit the infection.
    - **Intravenous route:** HBV can transmitted through transfusion of unscreened infected blood or blood products. This mode of spread is rare now, because of routine screening of all blood donors for HBV and HCV. Intravenous drug abuse with sharing of needles and syringes, tattooing, and acupuncture are other ways of developing infection.

  - **Close personal contact:** Nonparenteral route of transmission includes spread through body fluids (virus can be found in these fluids) such as saliva, urine, semen, and vaginal secretions. However, this requires close personal contact, unprotected **heterosexual or homosexual intercourse**.
- **Incubation period: 30–180 days** (mean, 8–12 weeks)
- **Chronic carrier state** can develop with HBV infection (1–20%).

Prevention and Prophylaxis

Q. Write short on prevention and prophylaxis of HBV.

- **Avoiding risk factors:**
  - Not to sharing of needles
  - Having safe sex
  - Transfuse safe blood and blood products
  - Enforced strict standard safety precautions in laboratories and hospitals to avoid accidental needle punctures and contact with infected body fluids
- **Active immunization:** By using recombinant vaccines (containing HBsAg). It is advised in following individuals:
  - **Children:** In India, nonpercutaneous routes of transmission are quite prevalent and active immunization using vaccine is recommended in all children.
  - **High-risk groups:** For example, healthcare personnel, hemodialysis patients, injection drug users, hemophiliacs and sexual contacts of HBsAg carriers.
- **Dosage regimen:** Three injections are given into the deltoid muscle at 0, 1, and 6 months. Dose is 10 µg for children under 10 years and 20 µg in children above 10 years. More frequent and larger doses are required in individuals over 50 years of age or clinically ill and/or immunocompromised (including HIV infection or AIDS). Side-effects are very few.
- **Combined prophylaxis:** This consists of vaccination and immunoglobulin. It should be given to individuals with:
  - Accidental needle stick injury, gross personal contamination with infected blood and exposure to infected blood in the presence of cuts and grazes
  - All newborn babies of HBsAg-positive mothers
  - Regular sexual partners of HBsAg-positive patients, who have been found to be HBV negative
  - Dosage: For adults, a dose 0.05–0.07 mL/kg bodyweight hepatitis B immunoglobulin (HBIG) (200 IU to newborns) and the vaccine (IM) given at another site.

Treatment: Pegylated interferon alpha, lamivudine, adefovir, entecavir, telbivudine, or tenofovir may be used as initial therapy but lamivudine and telbivudine are not preferred because of high rates of resistance.

Hepatitis C

Etiology

- Previously called bloodborne non-A, non-B hepatitis.
- It is a small**, enveloped**, **single-stranded RNA virus** belonging to the family Flaviviridae.
- A characteristic feature is emergence of an endogenous, newly mutated strain. Because of **genomic instability and antigenic variability, producing an effective HCV vaccine is difficult**.
- HCV has six genotypes and in India, most prevalent is **HCV3**.
- **Mode of spread:** HCV is not transmitted by breastfeeding.
  - It is mainly transmitted by the **parenteral route (transfusion** of blood and blood products, and in drug addicts) as a bloodborne infection
  - Sexual contact (low chances of transmission)
  - Perinatal/vertical transmission
- **Incubation period: 15–160 days** (mean, 7 weeks)
- Nearly 80% infected individuals develop chronic hepatitis.

Hepatitis D

Q. Write short note/essay on etiology and epidemiology of delta hepatitis.

Etiology

- Caused by hepatitis D virus (HDV or delta virus), which is a **defective/incomplete RNA virus** and belongs to the Deltaviridae family. The RNA genome is covered by an outer coat/shell of HBsAg.
- It has no independent existence and requires HBV for its replication and expression.

- Because HDV is dependent on HBV, the duration of HDV infection is determined by the duration of HBV infection. It causes **delta hepatitis (Hepatitis D)** with two clinical patterns.
  - i. **Acute coinfection:** It develops when individual is exposed simultaneously to serum, containing both HDV and HBV. The HBV infection first becomes established and the HBsAg is necessary for development of complete HDV virions.
  - ii. **Superinfection:** It occurs when an individual is already infected with HBV (chronic carrier of HBV) is exposed to a new dose HDV.
- **Mode of spread:** Parenteral route and sexual contact.
- Fulminant hepatitis can follow both patterns of infection but is more common after coinfection.

Hepatitis E

Q. Write short note/essay on transmission, clinical features, and management of hepatitis E infection.

It was previously called epidemic or enterically transmitted non-A, non-B hepatitis.

Etiology

- Hepatitis E virus (HEV) is an unenveloped, single-stranded RNA virus in the *Hepevirus* genus.
- Viral particles are 32–34 nm in diameter.
- Hepatitis E occurs primarily in young to middle-aged adults.
- **Source of infection:** HEV is a **zoonotic disease with animal reservoirs**, such as monkeys, cats, pigs, rodents, and dogs. Virions are shed in stool during the acute illness.
- **Mode of transmission:** An **enterically transmitted, waterborne** infection. It is common after contamination of water supplies such as after monsoon flooding.
- **Incubation period:** 14–60 days (mean, 5–6 weeks).

Outcome of Infection

- HEV infection is responsible for more than 30–60% of cases of sporadic acute hepatitis (clinically very similar to hepatitis A) in India. It **produces self-limiting acute hepatitis**.
- It **does not cause chronic liver disease**.
- **High mortality** rate (about 20%) among **pregnant women.**

Prevention and Control

- Good sanitation and hygiene similar to hepatitis A
- Vaccine has been developed and used successfully in China.

Clinical Features of Viral Hepatitis

Q. Write short note/essay on clinical features of acute hepatitis/hepatitis A/hepatitis B.

Phase 1: Incubation period

Varies according to the virus

Phase 2: Symptomatic preicteric phase

- Lasts for 1–2 weeks before onset of jaundice
- Prodromal symptoms—systemic and variable
- Constitutional symptoms—anorexia, nausea, vomiting, poor appetite, fatigue, malaise, headache, etc.
- Low-grade fever—more in hepatitis A and E than in hepatitis B or C
- Hepatitis B may be present with serum sickness-like immunological syndrome consisting of rashes and small joints polyarthritis.
- Upper vague abdominal pain due to stretching of liver capsule
- Dark urine and clay-colored stools

Phase 3: Symptomatic icteric phase

- With the onset of clinical jaundice, the constitutional prodromal symptoms usually diminish.
- Liver becomes enlarged and tender. Pruritus may develop due to bile salt retention.
- Splenomegaly and cervical lymphadenopathy may be observed in about 10–20% of patients
- Dark urine and pale stool

Phase 4: Recovery (convalescence) phase

- Symptoms disappear, appetite improves, jaundice decreases, stools and urine normal, and liver size decreases.
- Duration is variable, 2–12 weeks. It is more prolonged in acute hepatitis B and C.
- Complete clinical and biochemical recovery within 1–2 months in A and E and 3–4 months in B and C.

Fulminant Hepatitis

It can develop in hepatitis B, D, and E. It is uncommon with hepatitis C and rare in hepatitis A. With hepatitis E, fulminant hepatitis occurs in nearly 20% cases in pregnant females.

Summary of various hepatotropic viruses are presented in **Table 6.12**.

TABLE 6.12: Summary of various hepatotropic viruses.

Features	***HAV***	***HBV***	***HCV***	***HDV***	***HEV***
Incubation period in days (range)	30 (15–45)	90 (30–180)	50 (15–160)	90 (30–180)	40 (14–60)
Onset	Acute	Insidious or acute	Insidious	Insidious or acute	Acute
Age group affected	Children, young adults	Young adults, babies, toddlers	Adults, but any age	Any age (similar to HBV)	Young adults
Mode of transmission	Fecal-oral	Parenteral, sexual contact, perinatal	Parenteral, sexual contact, perinatal	Parenteral	Fecal-oral
Clinical					
Severity	Mild	Occasionally severe	Moderate	Occasionally severe	Mild
Chronicity	Never	10%	80%	5% with coinfection; ≤70% for superinfection	Never
Carrier state	None	1–30%	1.5–3.2%	Variable	None
Progression to cancer	None	+ (Neonatal infection)	+	±	None
Prognosis	Good	Worse	Moderate	Good in acute and poor in chronic	Good
Prophylaxis	Immunoglobulin Inactivated vaccine	Hepatitis B immunoglobulin, recombinant vaccine	None	HBV vaccine (none for HBV carriers)	Vaccine

Investigations

- **Urine**
  - **Bilirubinuria** (in early stages) and **increased urinary urobilinogen** slight microscopic hematuria and mild proteinuria
- **Hematological tests**
  - **Leukopenia with a relative lymphocytosis**
  - Prothrombin time (PT) is prolonged in severe cases which signifies extensive hepatocellular damage. This is one of the best indices of prognosis.
  - **Erythrocyte sedimentation rate (ESR) is raised**
- **Biochemical investigations**
  - **Aminotransferases (AST, ALT): Raised** and maximum levels are observed during the prodromal phase (400–4,000 IU/L). They progressively decline during icteric and recovery phases.
  - **Bilirubin:** Both conjugated and unconjugated bilirubin levels are equally **raised**.
  - **ALP:** It may be **raised** but usually less than two times the normal.
  - Serum protein: Normal
  - Blood glucose: It may below.
- **Serological tests:** During prodromal phase, low titers of antismooth muscle antibody, rheumatoid factor, antinuclear antibody, and heterophil antibody may be observed.

Serological Markers for Viral Hepatitis

Hepatitis A	
IgM anti-HAV	It appears at the onset of symptoms and is **reliable marker of acute infection.**
IgG anti-HAV	It persists for years and **provides lifelong immunity** against reinfection.
Hepatitis B	
HBsAg	➢ It is the **first** marker to appear in serum before symptoms, and is undetectable in 3–6 months. ➢ **Significance**: Presence in acute and chronic hepatitis B indicates **infectious state**. Loss of HBsAg with development of anti-HBs denotes recovery.

Contd...

Contd...

Anti-HBs	➢ Antibody to HBsAg, appears after disappearance of HBsAg. It is present on vaccination. ➢ **Significance**: **Protective antibody** may persist for life, providing protection.
IgM anti-HBc	➢ It appears in serum 1–2 weeks after appearance of HBsAg. ➢ **Significance: Earliest antibody marker** indicates recent infection (first 6 months). High titers in acute hepatitis B and low titers in chronic hepatitis B.
IgG anti-HBc	**Significance: It indicates remote infection** (beyond 6 months) and previous infection with HBV even when all the other viral markers are not detectable.
HBeAg	➢ It is detected transiently, early in the course. ➢ **Significance: Persistence** of 6 weeks after the onset **indicates infectivity, severe disease** progressing to **chronic hepatitis**. Absence is a favorable serologic finding.
Anti-HBe	**Significance:** It is found in **recovery phase** and **seroconversion.**
HBV DNA, DNA polymerase	➢ It is found in serum and liver soon after HBsAg appears. ➢ **Significance:** It is not helpful in diagnosis of hepatitis B but valuable in **assessing the prognosis**. It indicates **active viral replication.**
Hepatitis C	
Anti-HCV	It appears after infection, disappears after recovery, and persists in chronic hepatitis C.
HCV RNA	It appears after exposure.
Hepatitis D (Delta Hepatitis)	
HDV RNA	It is detectable in the blood and liver before and in the early days of acute disease.
Anti-HDV	IgM anti-HDV is the most reliable indicator of recent HDV exposure.
Hepatitis E	
HEV RNA, HEV virions	Before the onset of clinical illness, it can be detected in stool and serum.
IgM anti-HEV	After the onset of clinical illness, serum aminotransferases rises and elevated titers also occur simultaneously.
IgG anti-HEV	After recovery, the IgM is replaced with a persistent IgG anti-HEV titer.

Hepatitis B (Figs. 6.7 and 6.8)

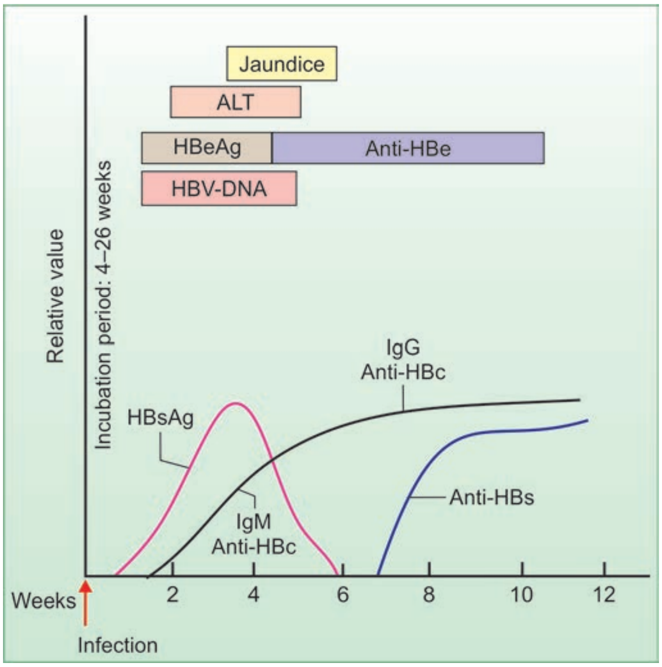


FIG. 6.7: Sequence of serologic markers in acute hepatitis with resolution caused by hepatitis B virus (HBV).

(ALT: Alanine aminotransferases; Anti-HBc: Antibodies against Hepatitis B core antigen; Anti-HBe: Antibodies against Hepatitis B e antigen; Anti-HBs: Antibodies against Hepatitis B surface antigen; DNA: Deoxyribonucleic acid; HBeAg: Hepatitis B e antigen; HBsAg: Hepatitis B surface antigen; Ig: Immunoglobulin)

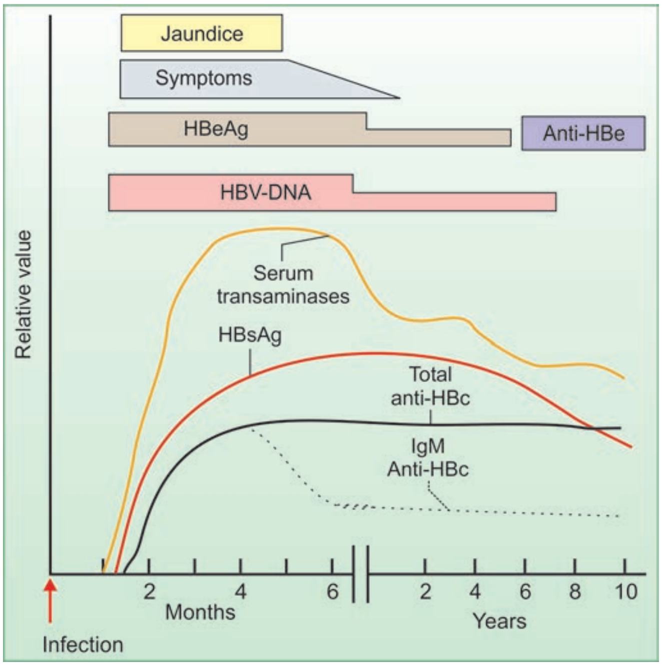

FIG. 6.8: Sequence of serologic markers in chronic hepatitis caused by hepatitis B virus (HBV).

(Anti-HBc: Antibodies against Hepatitis B core antigen; Anti-HBe: Antibodies against Hepatitis B e antigen; DNA: Deoxyribonucleic acid; HBeAg: Hepatitis B e antigen; HBsAg: Hepatitis B surface antigen; IgM: Immunoglobulin M)

Q. Write short note on HBsAg/Australia antigen/hepatitis B surface antigen.

Interpretations of serological findings and its significance in HBV are summarized in **Table 6.13**.
HBV viral DNA (HBV DNA): Most accurate marker of virus replication.

TABLE 6.13: Interpretation of serological findings and its significance in HBV.

Antigens		***Antibodies***			***Interpretation***
HBsAg	HBeAg	Anti-HBc	Anti-HBs	Anti-HBe	
–	–	–	–	–	Susceptible
–	–	–	+	–	Immunity to HBV caused by previous exposure or vaccination
+	+	IgM +ve and IgG –ve	–	–	**Acute hepatitis B**, highly infectious High titer in acute hepatitis B and low titer in chronic hepatitis B
–	–	IgM –ve and IgG +ve	+	+	**Resolved acute hepatitis B, seroconversion, low infectivity**
+	+	IgM –ve and IgG +ve	–	–	**Chronic infection** or carrier state, **high infectivity**
+	–	IgG +ve	–	+/–	**Chronic infection** or carrier state, **low infectivity**
–	–	–	+	–	**HBV vaccination**
–	–	+	–	–	**Interpretation unclear***
HBV DNA: (i) indicative of active viral replication, (ii) detected in both serum and liver, and (iii) indicates response to treatment					

*May be most commonly resolved infection, resolving acute infection, false +ve anti-HBc (thus susceptible) or chronic infection (low level).

Q. Write short note on complications of acute viral hepatitis.

Complications of Acute Viral Hepatitis (Table 6.14)

Hepatitis C

- **Anti-HCV:** It appears after the infection, disappears after the recovery, and persists in chronic hepatitis C.
- **HCV-RNA:** It appears after the exposure.
- **Anti-HCV** (antibodies against HCV) does not confer immunity.

Hepatitis D

- **HDV RNA:** Detectable in the blood and liver before and in the early days of acute disease.
- **Anti-HDV:** IgM anti-HDV is the most reliable indicator of recent HDV exposure.

Hepatitis E

- Before the onset of clinical illness, HEV RNA and HEV virions can be detected in stool and serum.
- After the onset of clinical illness, serum aminotransferases rise and elevated **IgM anti-HEV** titers also occur simultaneously. After recovery, the IgM is replaced with a persistent IgG anti-HEV titer.

Poor prognostic features of viral hepatitis are listed in **Table 6.15**.

TABLE 6.14: Complications of acute viral hepatitis.

Hepatic complications	***Extrahepatic complications***
Fulminant hepatic failure	Aplastic anemia
Cholestatic viral hepatitis	Renal failure
Relapsing hepatitis	Polyarteritis nodosa
Posthepatitis syndrome	Henoch–Schönlein purpura
Chronic hepatitis	Myocarditis
Cirrhosis	Transverse myelitis
Hepatocellular carcinoma	Peripheral neuropathy

TABLE 6.15: Poor prognostic features of viral hepatitis.

Laboratory findings	***Other features***
Marked increase in AST and ALT levels	Liver not enlarged
Serum bilirubin >20 mg/dL	Renal failure
Prolongation prothrombin time by more than 5 seconds than control	Recurring attacks of hypoglycemia
Low serum albumin	HBV, HCV, or HDV infections

Treatment

General Measures

- Avoid drugs which are metabolized in the liver, e.g., sedatives and narcotics.
- **Avoid alcohol** during the acute illness.
- No specific dietary modifications are required.
- Elective surgery should be avoided during acute viral hepatitis, as there is a risk of postoperative liver failure.
- Liver transplantation is performed for complications of cirrhosis resulting from chronic hepatitis B and C infection.

Hepatitis A

Q. Write a short note on treatment of hepatitis A infection.

- **No specific treatment**
- Rest and dietary measures are not helpful.
- Supportive symptomatic treatment
- Corticosteroids do not have benefit.

Hepatitis B

Q. Write a short note on treatment of hepatitis B infection.

Therapeutic goal

- It prevents the progression to end-stage liver disease, hepatocellular carcinoma (HCC), and death with improvement in quality of life.
- Clearance of HBV DNA
- Absence of HBeAg and HBsAg and appearance of antibody
- Normalization of liver enzymes and histology

Acute Hepatitis B

- In previously healthy adults, recovery occurs in ~99%; therefore, antiviral therapy is not required.
- Mainly symptomatic.
- Monitor HBV markers.
- Entecavir (ETV) or tenofovir (TDF) to be given when HBeAg persists beyond 12 weeks, and in patients who are very ill.

Postexposure: Prophylaxis to Prevent Hepatitis B Virus Infection (Described in detail in Chapter 4).

Hepatitis C

- Goals of treatment of HCV: (1) Eradication of virus, (2) reduce progression of disease, (3) histological improvement, and (4) decrease frequency of HCC.
- Interferon-∝ is used in acute hepatitis C to prevent chronic disease.
- HCV: Progression of fibrosis determines the prognosis and liver biopsy is the gold standard to assess fibrosis.

Hepatitis D

Active liver disease (raised ALT levels and/or inflammation on biopsy) is treated with peginterferon ∝-2a and adefovir for 12 months.

Transfusion-associated Hepatitis (TAH)

It includes HCV and/or HBV (discussed above).

CHRONIC HEPATITIS

Q. Discuss the classification, etiology, pathology, clinical features, complications, prevention, and management of chronic hepatitis/chronic hepatitis B infection.

Definition

Chronic hepatitis is defined as **symptomatic, biochemical, or serologic evidence of hepatic disease** for **more than 6 months**. Microscopically, there should be inflammation and necrosis in the liver.

Classification

Older classification: Previously chronic hepatitis was classified into:

- Milder forms: (i) Chronic persistent hepatitis (CPH), and (ii) chronic lobular hepatitis (CLH)
- Severe forms: Chronic active hepatitis (CAH)

However, this classification is not very helpful in determining the prognosis.

Present classification: In order to assess response to therapy and prognosis, present classification is based on combination of three factors **(Box 6.6)**.

Classification Based on the Causes of Chronic Hepatitis

See **Table 6.16**.

Box 6.6: Basis of present classification of chronic hepatitis.

- Etiology: Cause of hepatitis
- Grade: Histologic activity
- Stage: Degree of progression

TABLE 6.16: Classification based on the causes of chronic hepatitis.

Chronic viral hepatitis	Chronic hepatitis B ± hepatitis D, hepatitis C
Drug-associated chronic hepatitis	Methyldopa, isoniazid, ketoconazole, and nitrofurantoin
Autoimmune hepatitis	
Hereditary	Wilson's disease
Unknown cause	Cryptogenic chronic hepatitis
Others	Ulcerative colitis, rarely alcohol

***Classification*: Based on the grade of chronic hepatitis**

- Histological assessment of inflammation and necrosis observed on liver biopsy. Indicates severity of liver disease.
- Scoring system: Histologic activity index (HAI) and METAVIR score can be graded as mild, moderate, and severe.
    - **Interface hepatitis** (piecemeal/periportal necrosis)**: Spillover of inflammatory cells** (lymphocytes and plasma cells) from **portal tract into the adjacent** periportal hepatocytes at the limiting plate, with degenerating and apoptosis of periportal hepatocytes.
    - **Bridging necrosis:** Confluent necrosis of hepatocytes is observed in severe acute hepatitis. Forms bridges between **portal tract to portal tract**, **central vein to central vein, or portal-to-central** regions of adjacent lobules.
    - Degree of hepatocyte degeneration and focal intralobular necrosis
    - Degree of portal inflammation
    - **Fibrosis**: **Hallmark of chronic liver damage**.
- **Classification based on stage of chronic hepatitis:** It indicates level of progression and based on the degree of hepatic fibrosis **(Table 6.17)**.

TABLE 6.17: Modified histological activity index—Staging.

Degree of fibrosis	*Stage*
No fibrosis	0
Mild fibrosis of some portal areas	1
Moderate fibrosis of most portal areas	2
Severe fibrosis of most portal areas with occasional portal–portal (P–P) bridging	3
Fibrous expansion of portal areas with marked bridging of P-P and portal–central (P–C)	4
Marked bridging (P–P and/or P–C) with occasional nodules (incomplete cirrhosis)	5
Cirrhosis	6

Autoimmune Hepatitis

Q. Write short note on clinical features and treatment of autoimmune hepatitis.

Autoimmune hepatitis (AIH) is a **chronic and progressive (unresolving) hepatitis** of unknown cause. No features are absolutely diagnostic and are associated with **circulating autoantibodies and hypergammaglobulinemia.**

Clinical Features

- **It may be asymptomatic or** present with **fatigue** (most common)**, anorexia, jaundice, myalgia, and diarrhea**.
- **Acute hepatitis:** In about 30% of cases, it may present as acute hepatitis similar to viral hepatitis, which does not resolve with time.
- **Fulminant hepatic failure (FHF)** or **asymptomatic elevation of serum ALT.**
- **Cirrhosis:** In about 25% patients.
- **Jaundice** may be mild to moderate and is found in 69% of patients.

Investigations

Biochemical findings

- **Serum aminotransferases:** High and more than 10 times during relapses
- **Serum bilirubin:** Mildly raised usually less than 6 mg/dL
- **Serum ALP:** Mildly raised
- **Serum γ-globulins:** High; hypergammaglobulinemia is polyclonal; the IgG fraction predominates.
- **Serum albumin:** Low
- Serum alpha 1-antitrypsin, serum ceruloplasmin, iron and ferritin levels: Normal.

Autoantibodies

Classification of autoimmune hepatitis based on immunological markers and autoantibodies is presented in **Box 6.7**.

Other tests

- HBsAg and other viral markers: Negative
- Prothrombin time: Prolonged

Liver biopsy

Chronic hepatitis, variable amounts of interface hepatitis, cirrhosis, bridging necrosis.

Box 6.7: Classification of autoimmune hepatitis based on immunological markers.

Based on the differences in immunological markers AIH is divided into:

- **Type 1 AIH** is characterized by **anti-smooth muscle antibodies** (SMAs) and **antinuclear antibodies** (ANA), or both. Most commonly seen in females and associated with extrahepatic immunologic diseases such as autoimmune thyroiditis, Graves' disease, ulcerative colitis, rheumatoid arthritis, and Coombs-positive hemolytic anemia.
- **Type 2 AIH** is characterized by **antibodies to liver/ kidney microsome type 1 (anti-LKM1).** Most affected persons are children.
- **Type 3 AIH: Presence of antibodies to** soluble liver antigen/liver pancreas (anti-SLP/LP).

Treatment

- Prednisolone: 30 mg given orally daily for 2 weeks. Gradually tapering dose as LFT improves. Maintenance dose of 10–15 mg daily for at least 2 years after LFT has become normal.
- Azathioprine: Dose of 1–2 mg/kg daily, added as a steroid-sparing agent and some patients for sole long-term maintenance therapy or if dose of prednisolone is more than 10 mg/day.
- Other immunosuppressive agents: Mycophenolate, ciclosporin and tacrolimus for resistant cases.
- Duration of treatment: Lifelong in most cases
- Liver transplantation: If treatment fails

Course and Prognosis

- Exacerbations and remissions are common. Progression of steroid and azathioprine therapy produces remission in over 80% of patients.
- It may progress to hepatic failure and death.
- Some may develop cirrhosis and its complications.
- Hepatocellular carcinoma is uncommon.

Chronic Hepatitis B

Q. Write short note on complications of HBV infection.

- Chronic HBV infection occurs following an acute HBV infection (may be subclinical) and occurs **in about 1–10%** of patients.
- HBV infection is considered as chronic when the HBsAg (hepatitis B surface antigen) persists for more than 6 months.
- **It may progress to cirrhosis and HCC**.
- **Risk of chronic hepatitis:** Depends on:
  - **Age at which the contact of acute infection:** Chronic hepatitis occurs **more commonly with neonatal** (90%) **or childhood** (20–50% below the age of 5 years) **infection** rather than in adult life (<10%).
  - **Immune status:** In immunocompetent adults, the incidence of acute hepatitis is high while chronic infection is rare (1–2% of cases).

Other conditions where incidence of chronic hepatitis B infection is high are given in **Table 6.18**.

TABLE 6.18: Conditions associated with chronic hepatitis B state.

Down syndrome	Polyarteritis nodosa
Lepromatous leprosy	Patients on chronic hemodialysis
Leukemias	Needle using drug addicts
Hodgkin lymphoma	HIV infection

Phases of Chronic HBV Infection

1. **Immune-tolerant phase:** Characteristic features are:
   - **Asymptomatic** and frequent **in children**. Infection during birth or in early childhood develop prolonged immune-tolerant phase, and disease progresses even after the disappearance of HBeAg in some of these patients.
   - **Active viral replication** in liver but **little or no evidence of disease activity**.
   - **HBsAg and HBeAg positive** and **very high levels of serum HBV DNA.**
   - Normal LFTs
   - Liver biopsy shows no inflammation or fibrosis.
   - It may **lasts for decades**. Therefore, lifelong monitoring is necessary.
2. **Immune-active phase (chronic hepatitis):** Most patients with immune-tolerant phase progress to the immune-active phase.
   - **Vigorous immune response.**

   Criteria for chronic HBV active hepatitis are:
   - Liver biopsy shows **chronic hepatitis** with moderate or severe necroinflammation and fibrosis.
   - **Evidence of active HBV replication: High levels of HBV DNA and HBeAg**
   - Persistent or intermittent **elevation of serum aminotransferases** (ALT/AST)
3. **Inactive chronic hepatitis B—carrier phase with low replication:** Incidence varies. Most patients with chronic HBV infection will eventually enter inactive carrier phase.
   - **Criteria for carrier phase:**
   - **Serological findings:**
     - **HBsAg positive** in the serum >6 months.
     - **HBeAg negative** and **HBe antibody positive** (seroconversion from HBeAg to HBeAb).

        - **Undetectable or low levels** (below 400 IU/L) **of HBV DNA** in the serum.
        - **Normal aminotransferase** (ALT) levels.
    - **Liver biopsy** does not show any significant hepatitis.
    - **Low-risk for hepatocellular carcinoma**
    - Liver abnormalities generally do not progress to more severe disease.
    - Disease may be reactivated by severe immunosuppression (e.g., during chemotherapy for cancer or with bone marrow transplantation).

    Individuals **infected during adults or adolescents** usually **become inactive carriers** after they clear HBeAg.

4. **Chronic HBeAg-negative immune reactivation:**
    - Patients harbor HBV variants with mutations that prevent production or have low HBeAg.
    - HBV DNA levels are high, liver enzymes are raised, and active histological activity is present.
    - Late phase in the natural history of chronic HBV and often seen in older patients with advanced disease
    - HBV genotype C infection (prevalent in India) has an increased chance of developing cirrhosis and HCC.

Clinical Features

- Asymptomatic or may develop severe end-stage liver disease.
- **Symptoms: Fatigue, malaise, and anorexia**, persistent or intermittent jaundice.
- **During end-stage liver disease:** Symptoms due to complications of cirrhosis occur.
- **Extrahepatic manifestations:** Arthralgias, arthritis, vasculitis, glomerulonephritis, and polyarthritis nodosa.
- Mild hepatomegaly
- Long-standing cases **may develop HCC**.

PHASES OF CHRONIC HEPATITIS B INFECTION

Phase	*ALT*	*HBV DNA*	*HBeAg*	*Liver histology*
Immune tolerant	Normal	Elevated typically >1 million IU/mL	Positive	Minimal inflammation and fibrosis
HBeAg-postive immune active	Elevated	Elevated ≥20,000 IU/mL	Positive	Moderate-to-severe inflammation or fibrosis
Inactive chronic Hepatitis B	Normal	Low or undetectable <2,000 IU/mL	Negative	Minimal necroinflammation but variable fibrosis
HBeAg-negative immune reactivation	Elevated	Elevated ≥2,000 IU/ml	Negative	Moderate-to-severe inflammation or fibrosis

Investigations

Biochemical investigations:

- **Serum aminotransferase: Mildly elevated** but may be as high as 1,000 units. ALT (SGPT) tends to be more raised than compared to AST (SGOT). Once cirrhosis develops, AST levels exceeds ALT.
- **Serum bilirubin:** It may be normal or raised up to 10 mg/dL.
- **Serum proteins: Hypoalbuminemia** in severe cases and hyperglobulinemia.

Prothrombin time: Prolonged

Serological markers **(Box 6.8)**

Box 6.8: Serological markers of chronic hepatitis B.

- Positive HBsAg
- Positive IgG anti-HBc, negative IgM anti-HBc
- Positive HBe antigen or rarely, positive anti-HBe
- Positive HBV DNA

Treatment for Chronic Hepatitis B (Flowchart 6.1)

Criteria: Three criteria are used namely: (1) serum levels of HBV DNA, (2) serum levels of ALT, and (3) histological grade and stage.

- Serum HBV DNA above 2000 IU/mL (about >10,000 copies/mL)
- Serum ALT level greater than two times the normal
- Moderate-to-severe active necroinflammation and/or fibrosis in the liver biopsy

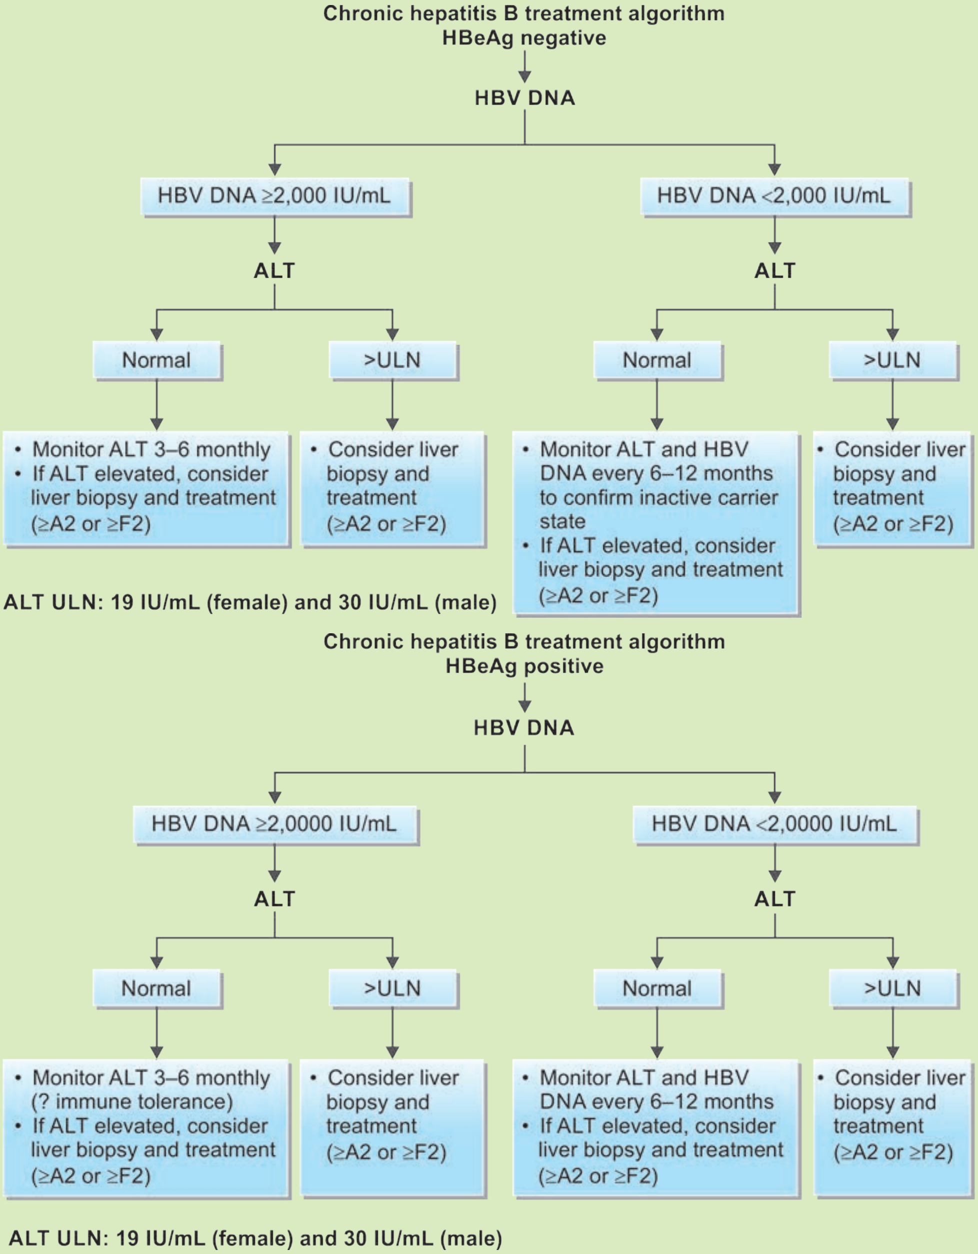
In **presence of cirrhosis** (compensated or decompensated), **oral antiviral agents** are recommended but liver transplantation may be necessary.

Patients without cirrhosis: Pegylated interferon, tenofovir, and entecavir are the preferred agents in **patients with clinically compensated cirrhosis**, entecavir or tenofovir (tenofovir alafenamide or tenofovir disoproxil fumarate) is preferred.

For patients with decompensated cirrhosis, interferon is **contraindicated**, and either entecavir or tenofovir should be used.

Immunotolerant patients, usually young with normal ALT and high HBV DNA levels, without evidence of liver disease do not need therapy, but be regularly followed-up.

FLOWCHART 6.1: Treatment algorithm for HBeAg-negative and HBeAg-positive chronic hepatitis B.



Chronic hepatitis B treatment algorithm
HBeAg negative

• If ALT elevated, consider liver biopsy and treatment (≥A2 or ≥F2)
• Consider liver biopsy and treatment (≥A2 or ≥F2)
ALT ULN: 19 IU/mL (female) and 30 IU/mL (male)

(HBeAg: Hepatitis B e antigen; HBV DNA: Hepatitis B DNA; ALT: Alanine transaminase; ULN: Upper limit normal)

Aim of treatment (Box 6.9)

Box 6.9: Aim of treatment of chronic hepatitis B.

- Seroconversion of HBeAg when present to anti-HBe. When HBeAg disappears, remission is usually attained for several years.
- Reduction of HBV DNA to 400 IU/L or less.
- Achieve normal levels of serum ALT.
- Histological improvement in inflammation and fibrosis in the liver biopsy
- Patients usually remain HBsAg positive, but loss of serum HBsAg indicates a good response.

Antiviral agents: Most commonly used drugs **(Box 6.10)** are:

- **Pegylated α-2a interferon**
  - Response (defined as loss of HBeAg and HBV DNA) occurs in 25–40% of cases.

Box 6.10: Drugs used for chronic hepatitis B.

- Peginterferon in combination with other agents:
  - Lamivudine plus peginterferon
  - Entecavir plus peginterferon
  - Tenofovir plus peginterferon
  - Adefovir plus peginterferon
  - Telbivudine plus peginterferon
- Lamivudine plus adefovir dipivoxil
- Tenofovir disoproxil plus entecavir
- Tenofovir disoproxil plus emtricitabine

  - **Dose:** 180 µg once a week subcutaneously and produces response after 48 weeks of treatment.
  - **Side effects:** Acute flu-like symptoms, malaise, headache, depression, reversible hair loss, bone marrow depression, thrombocytopenia, and infection.
  - Patients with HIV respond poorly and it should not be given to patient with cirrhosis.
- ***Entecavir:***
  - A cyclopentyl guanosine analog that is a very effective and quickly reduces HBV DNA by 48 weeks.
  - 0.5–1 mg daily
- ***Tenofovir:***
  - It is a cytosine nucleoside analog which is also very effective and has a similar potency to entecavir. It is used for HIV patients with HBV infection.
  - Tenofovir alafenamide (25 mg daily) OR tenofovir disoproxil fumarate (300 mg daily)
- ***Lamivudine:***
  - It is well tolerated. However, rate of development of viral resistance (80%) is high and itself may cause hepatitis. Hence, lamivudine monotherapy is no longer recommended.
  - Dosage is 100 mg/day given orally once a day until HBeAg becomes negative.
  - Used if coinfection with HIV
- ***Adefovir dipivoxil:***
  - A nucleotide reverse transcriptase inhibitor.
  - 10 mg daily is used in treatment of patients with lamivudine-resistant HBV
- ***Telbivudine:***
  - An L-nucleoside that may cause myopathy and neuropathy.
  - The recommended dose is 600 mg once daily.

Prognosis

- Development of chronic hepatitis depends on the age at which infection is acquired.
- Development of cirrhosis is associated with a poor prognosis.
- Hepatocellular carcinoma is one of the most common carcinomas in HBV-endemic areas.

TREATMENT STRATEGY	
Cirrhosis absent	
HBV DNA <2,000 IU/mL, normal ALT[a]	➢ No treatment ➢ Assess ALT levels every 6 to 12 months[b] ➢ If ALT becomes increased, check serum HBV DNA and exclude other causes of disease ➢ Consider therapy if significant histologic disease
HBV DNA ≥2,000 IU/mL, normal ALT[a]	
HBeAg-positive	➢ Consider treatment based on risk factors for developing HCC as well as patient's age, lifestyle, and desire to undergo treatment ➢ If treated, entecavir, TAF, or peginterferon alfa-2a are preferred ➢ Long-term treatment may be needed for oral agents
HBeAg-negative	➢ Treat if fibrosis is present. In the absence of histologic data, observe for rise in serum ALT ➢ If treated, entecavir, TAF, or peginterferon alfa-2a are preferred
HBeAg-positive and negative	➢ If not treated, assess ALT every 3–6 months, consider assessing for fibrosis ➢ Consider initiating treatment when ALT level increases or fibrosis is present
HBV DNA ≥2,000 IU/mL, elevated ALT[a]	➢ Treat ➢ Entecavir, TAF, TDF, or peginterferon alfa-2a are preferred ➢ Long-term treatment may be needed for oral agents
Cirrhosis present	
Compensated	➢ Treat ➢ Entecavir (0.5 mg), TAF (25 mg), or TDF (300 mg) ➢ Peginterferon alfa can be used in patients with well-compensated cirrhosis ➢ For oral antivirals, long-term treatment is required
Decompensated	➢ Treat ➢ Entecavir (1 mg) or TDF (300 mg)

Contd...

Contd...

	➢ TAF is not recommended ➢ Peginterferon alfa is contraindicated ➢ Long-term treatment is required ➢ Wait list for liver transplantation
HIV coinfection	
All patients with HBV and HIV	➢ Treat ➢ Avoid single-therapy HBV agent ➢ Long-term treatment required ➢ Pretreatment, assess fibrosis and screen for HCC ➢ Patients with platelets <120,000/μL or severe fibrosis should undergo endoscopy to detect varices
HBV treatment-naïve	➢ Preferred: (TDF or TAF) plus (emtricitabine or lamivudine) ➢ Entecavir plus HAART is also an option
Lamivudine-resistant HBV	Preferred: emtricitabine 200 mg and tenofovir disoproxil fumarate 300 mg or tenofovir plus entecavir

(ALT: Alanine aminotransferase; CHB: Chronic hepatitis B; HAART: Highly active antiretroviral therapy; HBeAg: Hepatitis B e antigen; HBV: Hepatitis B virus; HCC: Hepatocellular carcinoma; HIV: Human immunodeficiency virus; TAF: Tenofovir alafenamide; TDF: Tenofovir disoproxil fumarate)

[a] The upper limits of normal for serum ALT concentrations are 30 IU/L for men and 19 IU/L for women.

[b] Upon initial diagnosis, monitor every 3 months for 1 year to ensure stability.

Chronic Hepatitis C

Q. Write short note on complications of HCV.

- **Chronic hepatitis occurs in the majority (70–85%) of individuals infected by HCV** and is the hallmark of HCV infection.
- **Cirrhosis** develops **over 5–20 years in 20–30%** of patients, while HCC also develops in several patients, especially with cirrhosis.
- **Factors that accelerate progression** to advanced liver disease includes: **Alcohol consumption**, **coinfection with HIV or HBV**, and **older age** at the time of acquiring the infection.

Clinical Features

- **Usually asymptomatic**. Detected following a routine biochemical test when mild elevations in the aminotransferases (usually ALT) are detected.
- Clinical features **when present** are **similar to chronic hepatitis B**. Most common being fatigue and jaundice being rare.
- Extrahepatic features (**Table 6.19**).

Investigations

- **HCV antibody** in the serum is detected in more than 95% cases.
- **HCV RNA** detectable in all patients
- **Liver biopsy** is performed if active treatment is being considered. The histological changes are highly variable. It most commonly shows features of chronic hepatitis, often with **lymphoid follicles in the portal tracts**, and **fatty change.**
- Other laboratory features are similar to those seen in chronic hepatitis B.

Extrahepatic Manifestations of Hepatitis B and Hepatitis C Virus Infection

See **Table 6.19**.

TABLE 6.19: Extrahepatic manifestations of B and hepatitis C virus infection.

Hepatitis B virus infection	
Polyarteritis nodosa	Glomerulonephritis
Cryoglobulinemia	Serum sickness-like symptoms
Papular acrodermatitis (in children)	Aplastic anemia
Hepatitis C virus infection	
Proven associations ➢ Autoimmune thyroiditis ➢ B-cell non-Hodgkin's lymphoma ➢ Diabetes mellitus ➢ Lichen planus ➢ Mixed cryoglobulinemia ➢ Monoclonal gammopathies ➢ Porphyria cutanea tarda ➢ Glomerulonephritis	*Possible associations* ➢ Chronic polyarthritis ➢ Idiopathic pulmonary fibrosis ➢ Noncryoglobulinemic nephropathies ➢ Sicca syndrome ➢ Carcinoma of thyroid ➢ Renal cell carcinoma ➢ Vitiligo ➢ Cutaneous necrotizing vasculitis

Treatment of Chronic Hepatitis C (Tables 6.20 and 6.21)

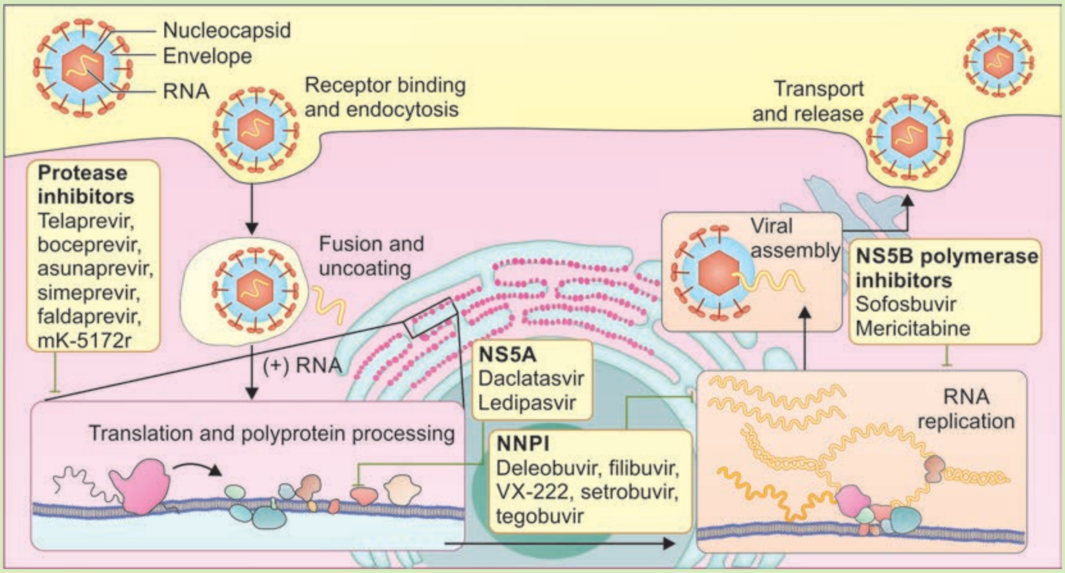
- **Indications for treatment:**
  - **Chronic hepatitis** on liver histology with **HCV RNA in the serum** and raised serum aminotransferases for more than 6 months.
  - Chronic hepatitis with persistently normal aminotransferases.
  - **Cirrhosis, fibrosis,** or **moderate inflammation** on liver biopsy (biopsy not mandatory).
- **The goal of antiviral therapy** in patients with chronic hepatitis C virus (HCV) is to eradicate HCV RNA, which is predicted by attainment of a sustained virologic response (SVR), defined as an undetectable RNA level 12 weeks following the completion of therapy**.**
- **Liver transplant:** For patients with decompensated **cirrhosis**.

TABLE 6.20: Drugs for the treatment of chronic hepatitis C.

Interferons and Pegylated Interferons
IFN alfa-2b and IFN alfa-2a Interferons **and Ribavirin**
Direct-acting antiviral agents (DAAs)
NS5B targeting polymerase inhibitors

- Nucleotide: Sofosbuvir
- Nonnucleotide: Dasabuvir

NS3/4 targeting protease inhibitors
Boceprevir, Telaprevir, Simeprevir, Prataprevir, Grazoprevir, Voxilaprevir
NS5A targeting agents
Ledipasvir, Daclatasvir, Ombitasvir, Elbasvir, Velpatasvir, Pibrentasvir



Nucleocapsid
Envelope
RNA
Receptor binding and endocytosis
Transport and release
Protease inhibitors
Telaprevir, boceprevir, asunaprevir, simeprevir, faldaprevir, mK-5172r
Fusion and uncoating
Viral assembly
NS5B polymerase inhibitors
Sofosbuvir
Mericitabine
(+) RNA
NS5A
Daclatasvir
Ledipasvir
RNA replication
Translation and polyprotein processing
NNPI
Deleobuvir, filibuvir, VX-222, setrobuvir, tegobuvir

TABLE 6.21: Antivirals for HCV infection in treatment-naive patients.

	Preferred	*Alternative*
Genotype 1 without cirrhosis	Daclatasvir/sofosburvir or ledipasvir/sofosbuvir	Simeprevir/sofosbuvir or ombitasvir/paritaprevir/ritonavir/dasabuvir ± ribavirin
Genotype 1 with cirrhosis	Daclatasvir/sofosburvir ± ribavirin or ledipasvir/sofosbuvir ± ribavirin	Simeprevir/sofosbuvir ± ribavirin or ombitasvir/paritaprevir/ritonavir/dasabuvir ± ribavirin
Genotype 2 with and without cirrhosis	Sofosbuvir/ribavirin	Daclatasvir/sofosbuvir
Genotype 3 without cirrhosis	Daclatasvir/sofosburvir or sofosbuvir/ribavirin	
Genotype 3 with cirrhosis	Daclatasvir/sofosburvir ribavirin	Sofosbuvir/pegylated interferon/ribavirin
Genotype 4 without cirrhosis	Daclatasvir/sofosburvir or ledipasvir/sofosbuvir	Simeprevir/sofosbuvir or ombitasvir/paritaprevir/ritonavir/ribavirin
Genotype 4 with cirrhosis	Daclatasvir/sofosburvir ± ribavirin or ledipasvir/sofosbuvir ± ribavirin	Simeprevir/sofosbuvir ± ribavirin or ombitasvir/paritaprevir/ritonavir/ribavirin
Genotype 5 or 6 with and without cirrhosis	Ledipasvir/sofosbuvir	Simeprevir/pegylated interferon/ribavirin

(HCV: Hepatitis C virus; IFN: Interferon; P: Pegylated interferon-alfa 2a or 2b; R: Ribavirin; r: Ritonavir)

Standard of care of patients with HCV infection*.

Genotypes	*Stage of liver disease*	*Prior treatment experience*	*Sofosbuvir/ Velpatasvir*	*Glecaprevir/ Pibrentasvir*	*Grazoprevir/Elbasvir*
Genotypes 1a, 1b, 2, 4, 5 and 6	Chronic hepatitis	Treatment-naive	12 weeks	8 weeks	12 weeks (GT 1b only)
		Treatment-experienced			
	Compensated cirrhosis	Treatment-naive			
		Treatment-experienced		12 weeks	
Genotype 3	Chronic hepatitis	Treatment-naive	12 weeks	8 weeks	No
		Treatment-experienced		12 weeks	No
	Compensated cirrhosis	Treatment-naive	12 weeks with Ribavirin	8 weeks	No
		Treatment-experienced		16 weeks	No

*Adapted by EASL recommendation.

ACUTE LIVER FAILURE

Q. Define fulminant hepatic failure. Discuss the causes, pathology, clinical features, investigations, complications, and management of fulminant hepatic failure.

Q. Enumerate the precipitating causes of hepatic coma in a case of chronic liver disease. Discuss the diagnosis and treatment of hepatic coma.

Definition

Acute liver failure is defined as the rapid progressive deterioration in the liver function, specifically coagulopathy [elevated prothrombin time/international normalized ratio (INR)] and mental status changes (encephalopathy) in a patient without known prior liver disease.

Classification of Acute Liver Failure

Acute liver failure is subclassified into hyperacute, acute, and subacute, depending on the interval between onset of jaundice and encephalopathy.

1. **Hyperacute hepatic failure:** If encephalopathy develops within 7 days, it is called **hyperacute hepatic failure** and has better prognosis than acute hepatic failure.
2. **Acute/FHF:** In this, encephalopathy develops within 3 weeks (7–21 days) from onset of symptoms in a patient with a previously normal liver.
3. **Subacute hepatic failure:** If hepatic failure develops at a slower pace (>21 days and <26 weeks), it is called **subacute or subfulminant hepatic failure.**

Note: Chronic liver failure is an illness with a duration of >26 weeks.

Fulminant Hepatic Failure

It is defined as severe hepatic failure (insufficiency) in which encephalopathy develops within **8 weeks** from onset of symptoms in a patient with a previously normal liver.

Etiology: FHF is a rare but often life-threatening condition and the various causes of FHF are listed in **Table 6.22**.

Clinical Features

1. **General features:**
   - Jaundice, weakness, nausea, and vomiting
   - Pain in the right hypochondrium
   - Small liver and liver dullness are absent on percussion.
   - Ascites and edema develop later.
2. **Features of hepatic encephalopathy:**
   - **Mental state:** It varies from mild drowsiness, confusion, and disorientation (grades I and II) to unresponsive coma (grade IV) with convulsions.
   - **Fetor hepaticus and flapping tremor** (asterixis) is common.
   - Ascites and splenomegaly are rare.
   - Fever, vomiting, hypotension and hypoglycemia may be observed.
   - Spasticity and extension of the arms and legs and plantar responses remain flexor until late.
3. **Features of cerebral edema:** Cerebral edema develops in ~80% of patients.
   - Bradycardia, intracranial hypertension, and irregular respiration (Cushing's triad).
   - Pupils: Unequal or abnormally reacting or fixed pupils
   - Hyperventilation and hyperreflexia.
   - Consequences: Intracranial hypertension and brain herniation are the most common causes of death.

TABLE 6.22: Important causes of fulminant hepatic failure.

A. **Viruses:** HAV and HAB. Occasionally, HCV, HEV and others (VZV, HSV, EBV, CMV)
B. **Noninfectious causes**
1. Drugs: Important examples include: – Analgesics (e.g., paracetamol) – Monoamine oxidase inhibitors – Antituberculosis (e.g., isoniazid) – Antiepileptic (e.g., valproate) – Halogenated anesthetics – 'Social' drugs (e.g., "Ecstasy")
2. Toxins: Mushroom—*Amanita phalloides*, rodenticides, heavy metals (copper)
3. Miscellaneous: – Wilson's disease – HELLP syndrome – Eclampsia, preeclampsia – Acute fatty liver of pregnancy – Reye's syndrome – Autoimmune hepatitis – Budd-Chiari syndrome – Shock, ischemic hepatitis – Heat stroke – Neoplastic infiltration
4. Unknown (15–30% cases)

Investigations

Investigations to determine the cause of acute liver failure:

- **Serum findings:**
  - **Hyperbilirubinemia:** Serum bilirubin is raised.
  - **Serum aminotransferases are raised** but are not useful indicators of the course of the disease as they tend to fall with progressive liver damage.
  - **Coagulation factors are decreased** including prothrombin and factor V. Prothrombin time is prolonged.
  - Serum proteins: **Hypoalbuminemia**
  - **Plasma and urine amino acids are increased.**
  - **Blood ammonia levels: Raised.**
- **Urine** shows protein, bilirubin, and urobilinogen.
- **Peripheral blood:** Leukocytosis and thrombocytopenia.
- **EEG:** It may be help in grading the encephalopathy.
- **Ultrasound*:*** To detect the liver size and for any evidence of underlying liver pathology
- **CSF*:*** Intracranial pressure is raised, but CSF is normal.

TABLE 6.23: Complications of fulminant hepatic failure.

Encephalopathy	Bacterial and fungal infections
Cerebral edema	Gastrointestinal bleeding, hypotension
Respiratory failure	Hypoglycemia, hypokalemia
Renal failure	Hypothermia
Pancreatitis	Acid–base imbalance
Hypocalcemia, hypomagnesemia	

Complications of FHF are listed in **Table 6.23**.

Pathogenesis and management of major complications of acute liver failure are given in **Table 6.24.**

TABLE 6.24: Pathogenesis and management of major complications of acute liver failure.

Complication	***Pathogenesis***	***Management***
Hypoglycemia	Diminished hepatic glucose synthesis	➢ Blood glucose monitoring ➢ Intravenous (IV) glucose supplementation (10–20% dextrose)
Encephalopathy	Cerebral edema	➢ ICP monitoring (if stage 3 or 4 encephalopathy) ➢ CT scan (if advanced encephalopathy) ➢ Elevate head of the bed >30° ➢ Consider osmotherapy (mannitol) or barbiturates ➢ Treat other contributing factors ➢ Reduce fever (cooling blankets, antibiotics) ➢ Avoid benzodiazepines and sedative medications ➢ Moderate hypothermia
Infections	Reduced immune function Invasive procedures	➢ Aseptic medical, nursing care ➢ Daily cultures: Blood, urine, and sputum ➢ High index of suspicion: Bacterial/fungal infection ➢ Antibiotics: Gram-negative, anaerobes, skin flora ➢ Consider antifungal therapy if patient worsens, despite antibacterial coverage
GI hemorrhage	Stress ulceration	➢ Nasogastric tube placement ➢ IV H_2-receptor antagonist or proton pump inhibitor
Coagulopathy	Reduced clotting factor synthesis Thrombocytopenia Fibrinolysis	➢ Parenteral vitamin K ➢ Platelet or plasma infusions for bleeding and before procedures ➢ Cryoprecipitate for bleeding with hypofibrinogenemia ➢ Recombinant factor VIIa
Hypotension	Hypovolemia Decreased vascular resistance	➢ Hemodynamic monitoring of central venous pressures ➢ Volume repletion with blood or colloid ➢ α-adrenergic agents
Respiratory failure	ARDS	➢ Hemodynamic monitoring of central venous pressures ➢ Mechanical ventilation
Pancreatitis	Hypoxia	➢ Supportive care, supplemental oxygen if needed ➢ Abdominal CT to exclude necrotizing pancreatitis
Renal failure	Hypovolemia Hepatorenal syndrome Acute tubular necrosis	➢ Hemodynamic monitoring of central venous pressures ➢ Volume repletion with blood or colloid ➢ Avoidance of nephrotoxic agents (e.g., aminoglycosides, NSAIDs, contrast dye) ➢ Oral *N*-acetylcysteine prior to IV contrast agent ➢ Hemofiltration, dialysis

(ARDS: Acute respiratory distress syndrome; CT: Computed tomography; ICP: Intracranial pressure; GI: gastrointestinal; NSAIDs: Nonsteroidal anti-inflammatory drugs)

Prognosis: The mortality is ~80% without liver transplantation, and ~35% with transplantation.

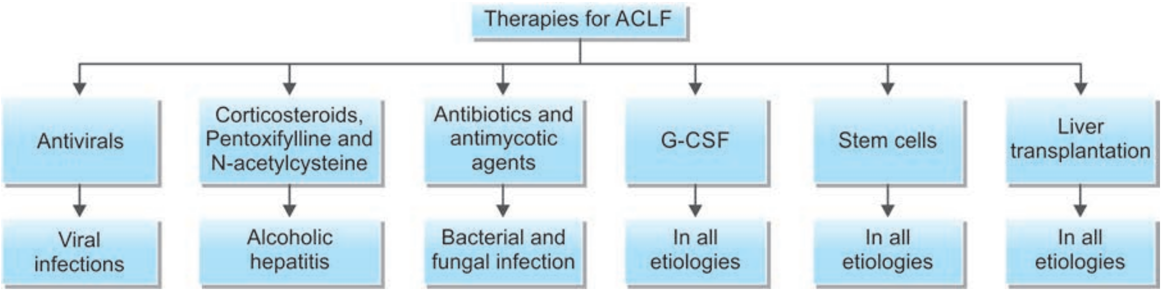
Reye's Syndrome

- Reye/Reye's syndrome is a rapidly progressive encephalopathy with hepatic dysfunction, which begins several days after apparent recovery from a viral illness, especially varicella or influenza A or B. History of aspirin intake may be present.
- **Liver shows severe fatty change.**
- **Raised ammonia levels and liver enzymes**
- Usually no jaundice

Acute-on-Chronic Liver Failure (Flowchart 6.2)

- Acute-on-chronic liver failure (ACLF) is a multifaceted condition with poor treatment options and high short-term mortality.
- ACLF can develop in patients with or without liver cirrhosis, where patients with decompensated cirrhosis display a higher risk of short-term mortality.
- Pathophysiological mechanisms include systemic inflammation due to bacterial and fungal infections and acute hepatic insult with drug, alcohol, and viral hepatitis. The clinical outcome of patients with ACLF gets further complicated by the occurrence of variceal hemorrhage, hepatorenal syndrome, hepatic encephalopathy, and systemic immune dysfunction.

FLOWCHART 6.2: Management of ACLF.



FATTY LIVER

Q. List causes of fatty liver.

Fatty liver (steatosis) is **abnormal accumulations of triglycerides within** cytosol of the **parenchymal cells**.

Causes of Fatty Liver (Table 6.25)

TABLE 6.25: Various causes of fatty liver.

Alcohol
Nonalcoholic fatty liver disease/Nonalcoholic steatohepatitis
Drugs: Glucocorticoids, amiodarone, tetracycline, aspirin, methotrexate, didanosine, zidovudine, tamoxifen, amiodarone
Nutritional: Protein–calorie malnutrition, total parenteral nutrition, and rapid weight loss/obesity
Metabolic: Diabetes, lipodystrophy, and acute fatty liver of pregnancy
Miscellaneous: Inflammatory bowel disease, HIV infection, chronic hepatitis C, toxic mushrooms (*Amanita phalloides*), Reye's syndrome, obstructive sleep apnea, and Indian childhood cirrhosis

Metabolic-associated Fatty Liver Disease (MAFLD)/Metabolic Dysfunction-associated Steatotic Liver Disease (MASLD), Nonalcoholic Fatty Liver Disease, Nonalcoholic Steatosis and Nonalcoholic Steatohepatitis

Q. Write short note on nonalcoholic fatty liver disease and nonalcoholic steatohepatitis.

Nonalcoholic fatty liver disease is a disease of affluent societies. Its prevalence increases in proportion to the rise in obesity. Its progression accounts for the majority of cryptogenic cirrhosis.

It is increasingly recognized condition and is the most common cause of chronic liver disease after hepatitis B, hepatitis C, and alcohol.

For nonalcoholic steatohepatitis (NASH) clinical trials, it has been defined as ongoing or recent consumption of more than 14 standard drinks on average per week in women and more than 21 standard drinks on average per week in men.

Non alcoholic fatty liver disease is most often diagnosed incidentally on imaging or when it presents with complications.

Metabolic (dysfunction)-associated fatty liver disease (MAFLD) is defined as hepatic steatosis entity in addition to the presence of overweight or obesity, diabetes mellitus, or evidence of metabolic dysfunction.

The prevalence of NAFLD in western countries is around 20 to 30%.

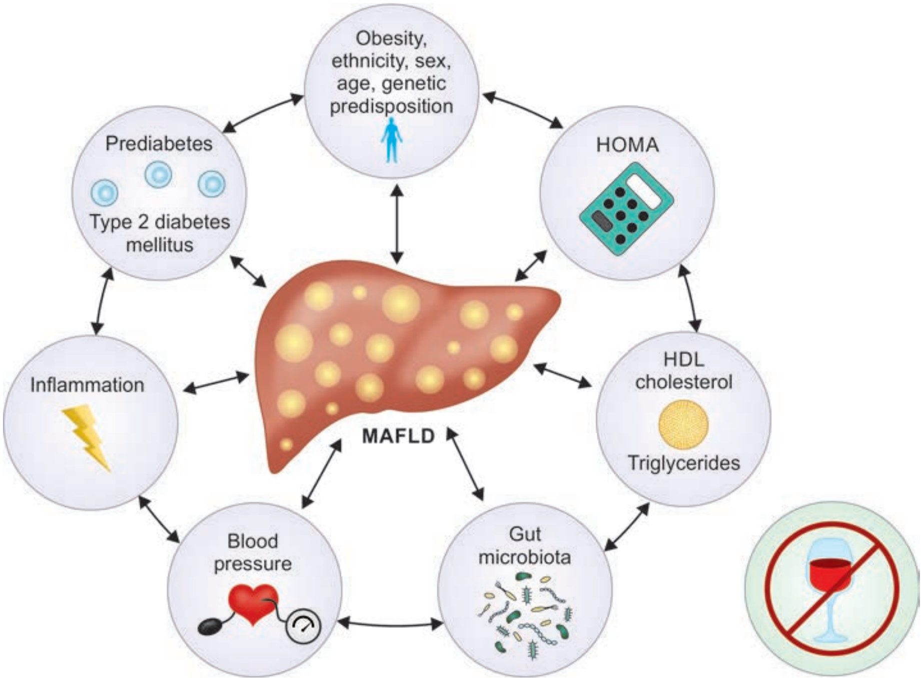
Classification

Nonalcoholic fatty liver disease (NAFLD) is now **metabolic dysfunction-associated steatotic liver disease (MASLD)**. MASLD encompasses patients who have hepatic steatosis and have at least one of five cardiometabolic risk factors. A new category, outside of pure MASLD, termed **MetALD** (pronunciation: Met A-L-D) was selected to describe those with MASLD who consume greater amounts of alcohol per week (140 g/week and 210 g/week for females and males respectively). Those with no metabolic parameters and no known cause have cryptogenic SLD. Metabolic dysfunction-associated steatohepatitis (MASH) is the replacement term for nonalcoholic steatohepatitis (NASH).

Risk Factors for NAFLD

Increased prevalence in those with the metabolic syndrome. NAFLD is considered to be the liver manifestation of metabolic syndrome **(Fig. 6.9)**.

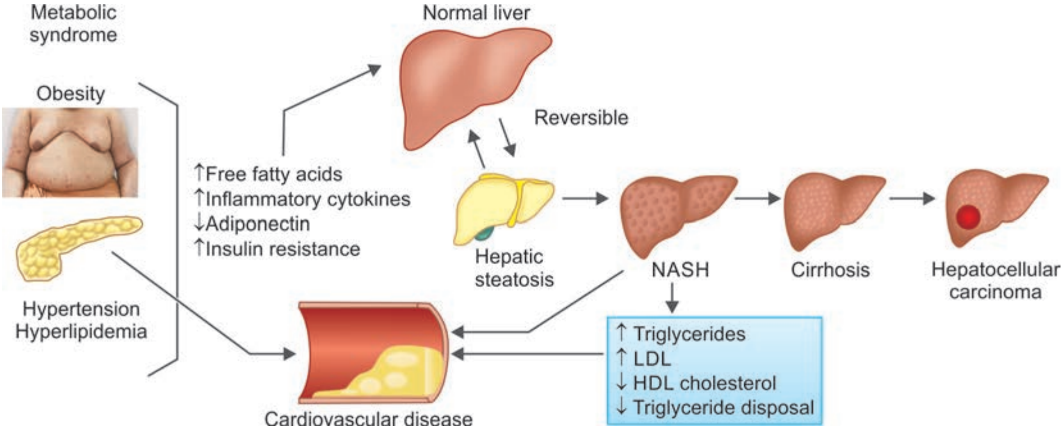
- **Obesity, hypertension, type 2 diabetes mellitus, hyperlipidemia, and insulin resistance.** About 50 to 70% of people with diabetes are found to have NAFLD.
- **Rare causes:** Tamoxifen, amiodarone and exposure to certain petrochemicals.



Obesity, ethnicity, sex, age, genetic predisposition
Prediabetes
Type 2 diabetes mellitus
HOMA
Inflammation
MAFLD
HDL cholesterol
Triglycerides
Blood pressure
Gut microbiota

FIG. 6.9: Risk factors for MAFLD.
(HOMA: Homeostatic model assessment; HDL: high-density lipoprotein; MAFLD: Metabolic-associated fatty liver disease)

- **Pathogenesis:** NASH is induced by two consecutive steps: Excess fat accumulation and subsequent necroinflammation in the liver **(Fig. 6.10)**.



Metabolic syndrome
Obesity
Hypertension
Hyperlipidemia
↑Free fatty acids
↑Inflammatory cytokines
↓Adiponectin
↑Insulin resistance
Normal liver
Reversible
Hepatic steatosis
NASH
Cirrhosis
Hepatocellular carcinoma
↑ Triglycerides
↑ LDL
↓ HDL cholesterol
↓ Triglyceride disposal
Cardiovascular disease

FIG. 6.10: Pathogenesis of nonalcoholic fatty liver disease (NAFLD).
(NASH: nonalcoholic steatohepatitis; LDL: low-density lipoprotein; HDL: high-density lipoprotein)

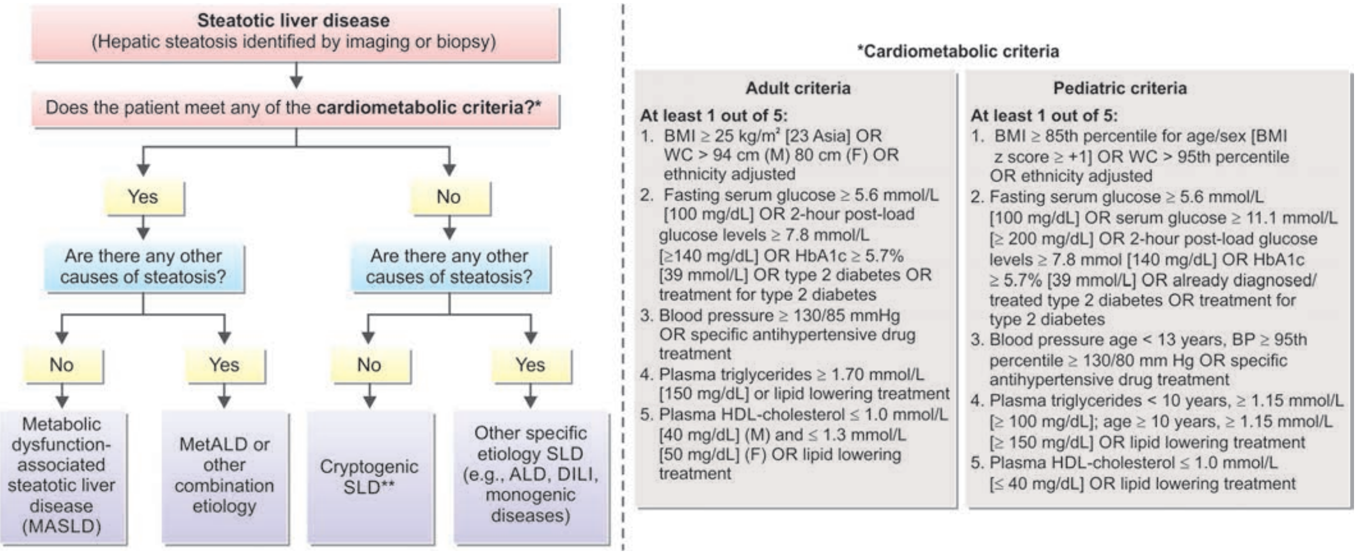
Clinical Features

- Most are **asymptomatic** at the time of diagnosis and many patients are **obese.**
- Some have fatigue, malaise, and a sensation of fullness in the upper abdomen.
- **Hepatomegaly** is the only sign in most patients.

Diagnosis of MASLD

Patient with mild-to-moderately elevated serum transaminases, no history of alcohol abuse and a negative chronic liver disease screen.

Diagnostic Criteria of MASLD



Steatotic liver disease
(Hepatic steatosis identified by imaging or biopsy)
Does the patient meet any of the cardiometabolic criteria?*
Yes
No
Are there any other causes of steatosis?
Are there any other causes of steatosis?
No
Yes
No
Yes
Metabolic dysfunction-associated steatotic liver disease (MASLD)
MetALD or other combination etiology
Cryptogenic SLD**
Other specific etiology SLD (e.g., ALD, DILI, monogenic diseases)

*Cardiometabolic criteria

Adult criteria

At least 1 out of 5:

1. BMI ≥ 25 kg/m^2 [23 Asia] OR WC > 94 cm (M) 80 cm (F) OR ethnicity adjusted
2. Fasting serum glucose ≥ 5.6 mmol/L [100 mg/dL] OR 2-hour post-load glucose levels ≥ 7.8 mmol/L [≥140 mg/dL] OR HbA1c ≥ 5.7% [39 mmol/L] OR type 2 diabetes OR treatment for type 2 diabetes
3. Blood pressure ≥ 130/85 mmHg OR specific antihypertensive drug treatment
4. Plasma triglycerides ≥ 1.70 mmol/L [150 mg/dL] or lipid lowering treatment
5. Plasma HDL-cholesterol ≤ 1.0 mmol/L [40 mg/dL] (M) and ≤ 1.3 mmol/L [50 mg/dL] (F) OR lipid lowering treatment

Pediatric criteria

At least 1 out of 5:

1. BMI ≥ 85th percentile for age/sex [BMI z score ≥ +1] OR WC > 95th percentile OR ethnicity adjusted
2. Fasting serum glucose ≥ 5.6 mmol/L [100 mg/dL] OR serum glucose ≥ 11.1 mmol/L [≥ 200 mg/dL] OR 2-hour post-load glucose levels ≥ 7.8 mmol [140 mg/dL] OR HbA1c ≥ 5.7% [39 mmol/L] OR already diagnosed/treated type 2 diabetes OR treatment for type 2 diabetes
3. Blood pressure age < 13 years, BP ≥ 95th percentile ≥ 130/80 mm Hg OR specific antihypertensive drug treatment
4. Plasma triglycerides < 10 years, ≥ 1.15 mmol/L [≥ 100 mg/dL]; age ≥ 10 years, ≥ 1.15 mmol/L [≥ 150 mg/dL] OR lipid lowering treatment
5. Plasma HDL-cholesterol ≤ 1.0 mmol/L [≤ 40 mg/dL] OR lipid lowering treatment

(SLD: Steatotic liver disease; ALD: Alcohol-related liver disease; DILI: Drug-induced liver injury)

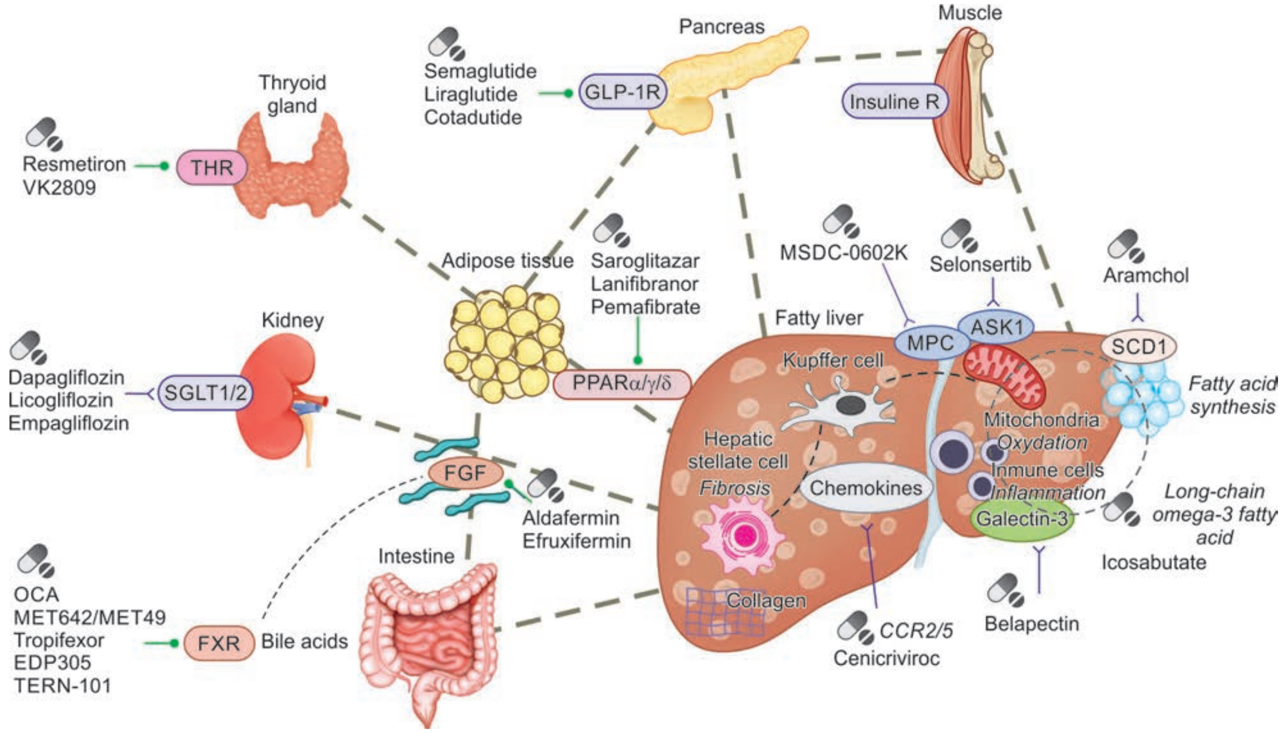
Investigations

- **Mild elevation of serum aminotransferases** is frequently the sole abnormality with AST: ALT <1. This ratio increases as fibrosis advances. It may be only isolated elevation of the GGT. ALP is elevated in about 30% of patients.
- **The alcoholic liver disease to NAFLD index (ANI):**
  - ANI = –58.5 + 0.637 (MCV) + 3.91 (AST/ALT) – 0.406 (BMI) + 6.35 for men
  - An ANI greater than zero favors a diagnosis of alcoholic liver disease, whereas an ANI less than zero favors a diagnosis of NAFLD.
- Ferritin levels are increased in 20–50% of patients.
- Autoantibodies are found in about 25% patients with more advanced fibrosis.
- Ultrasound and CT features: Similar to those in alcoholic fatty liver.
- **Liver biopsy:**
  - **Best diagnostic tool for confirmation and staging the disease**.
  - Microscopic changes are **similar to those of alcohol-induced** hepatic injury and range from simple fatty change to fat and inflammation (steatohepatitis) and fibrosis. NASH is characterized by fat, Mallory bodies, neutrophil infiltration, and pericellular fibrosis.

Management/Treatment

- Weight loss, control of diabetes, and hyperlipidemia in the early stages.
- Some drugs such as metformin, thiazolidinediones (e.g., pioglitazone), liraglutide, ursodeoxycholic acid (UDCA), vitamin E, orlistat, obeticholic acid, aramchol, betaine, losartan, pentoxifylline and atorvastatin have shown some promise.
- Liver transplantation is done for end-stage cirrhosis. Unfortunately, it may recur in the graft.
- Regular follow-up, particularly for steatohepatitis.

Main Drugs and Targets in NASH/MAFLD Treatment



Pancreas
Muscle
Semaglutide
Liraglutide
Cotadutide
GLP-1R
Insuline R
Thryoid gland
Resmetiron
VK2809
THR
Adipose tissue
Saroglitazar
Lanifibranor
Pemafibrate
MSDC-0602K
Selonsertib
Aramchol
Kidney
Fatty liver
MPC
ASK1
SCD1
Dapagliflozin
Licogliflozin
Empagliflozin
SGLT1/2
PPARα/γ/δ
Kupffer cell
Fatty acid synthesis
Mitochondria
Oxydation
Hepatic stellate cell
Fibrosis
Chemokines
Inmune cells
Inflammation
Galectin-3
Long-chain omega-3 fatty acid
FGF
Aldafermin
Efruxifermin
Icosabutate
Intestine
Collagen
OCA
MET642/MET49
Tropifexor
EDP305
TERN-101
FXR
Bile acids
CCR2/5
Cenicriviroc
Belapectin

(FXR: Farnesoid-X-receptor; FGF: Fibroblast growth factor; GLP-1R: Glucagon like peptide-1 receptor; THR: Total hip replacement; SGLT1/2: Sodium-glucose cotransporter-1/2; PPAR: Peroxisome proliferator-activated receptor; ASK1: Apoptosis-signal regulating kinase 1; MPC: Mitochondrial pyruvate carrier; SCD1: Stearoyl-coenzyme A desaturase 1)

ALCOHOLIC LIVER DISEASE

Q. IM5.5 Describe and discuss the pathophysiology and clinical evolution of alcoholic liver disease.

Q. List the types of alcoholic liver diseases. Discuss the clinical features and management of alcoholic hepatitis.

Chronic and excessive consumption of alcohol can produce a wide spectrum of liver disease which can be divided mainly into four major lesions:

1. Fatty liver
2. Alcoholic hepatitis
3. Alcoholic cirrhosis
4. Hepatocellular carcinoma (HCC)

Threshold for alcohol and risk of alcoholic liver disease: Generally, the effects of alcohol are worse in women compared to men and amount of alcohol with degree of risk in male are presented in **Table 6.26**.

For women, the above figures should be reduced by 50%. Alcohol by volume (ABV) of various alcoholic beverages is shown in **Box 6.11**.

TABLE 6.26: Amount of alcohol consumption and its associated risk of alcoholic liver disease in male.

Amount of ingestion per day	*Degree of risk*
160 g ethanol (20 single drinks)	High
80 g ethanol (10 single drinks)	Medium
40 g ethanol (5 single drinks)	Low

Box 6.11: Alcohol percentage content.

- Vodka | ABV: 40–95%
- Gin | ABV: 36–50%
- Rum | ABV: 36–50%
- Whiskey | ABV: 36–50%
- Tequila | ABV: 50–51%
- Liqueurs | ABV: 15%
- Fortified Wine | ABV: 16–24%
- Unfortified Wine | ABV: 14–16%
- Beer | ABV: 4–8%
- Malt beverage | ABV: 5–15%

Note: ABV: alcohol by volume. ABV: milliliters (mL) of pure ethanol present in 100 mL of solution at 20°C.

Alcoholic Fatty Liver (Alcoholic Steatosis)

Clinical Features

- It is asymptomatic.
- Occasionally, it may present with discomfort in right upper quadrant, nausea, and jaundice.
- Most common feature is **hepatomegaly** with or without tenderness.
- Progression to cirrhosis is not common with its associated complications.

Investigations

- **Biochemical findings:**
  - Moderately **raised ALT and AST with AST: ALT >1.**
  - γ-GT level is a sensitive test to determine whether the individual is taking alcohol.
- **Ultrasound:** Diffuse increase in echogenicity
- **CT scan:** Fatty infiltration produces a low-density liver.
- **Liver biopsy: It shows accumulation of fat in perivenular hepatocytes and later in entire hepatic lobule.**

Treatment: Complete cessation of alcohol consumption and nutritional support results in normalization of biochemical findings and histological changes.

Alcoholic Hepatitis

Clinical Features

- It may be **asymptomatic or present with fever, rapid onset of jaundice**, **abdominal discomfort,** and proximal muscle wasting.
- Portal hypertension, spider nevi, ascites, and bleeding due to esophageal varices can occur without cirrhosis.
- Hepatomegaly (tender) and splenomegaly.

Investigations

- Biochemical findings:
  - **Serum aminotransferase (AST and ALT) raised** to 2–7 times of normal (usually < 400 IU)
  - **AST: ALT ratio is >1 (generally >2)**
  - Raised bilirubin
  - Mildly elevated serum ALP
  - Decreased albumin
- **Hematological findings:** Prolonged prothrombin time and leukocytosis.
- **Liver biopsy: Ballooning degeneration** of hepatocytes with **leukocyte infiltration. Mallory bodies are** often seen. They are potentially reversible but many progress to cirrhosis.

Prognosis

- **Variable** and despite abstinence, the liver disease progresses in many patients. Conversely, a few patients continue to drink heavily without developing cirrhosis.
- Mortality is high in patients with severe alcoholic hepatitis.
- Poor prognostic factors (**Box 6.12**)

Maddrey's discriminant function (DF) = (4.6 × [prothrombin time (sec) – control prothrombin time (sec)]) + (serum bilirubin)

The **ABIC** (age, bilirubin, INR, and creatinine) is a modification of the MELD score. An ABIC score >9 is associated with approximately 80% mortality at 90 days.

The Lille Model Score helps to identify patients 'early' with severe alcoholic hepatitis that are likely to respond to steroid therapy or who will require alternative treatment options. Simple baseline data was obtained (age, presence of renal insufficiency*, albumin, prothrombin time, and bilirubin level).

Box 6.12: Poor prognostic factors of alcoholic hepatitis.

- Prothrombin time >5 seconds of control
- Anemia
- Albumin <2.5 g/dL
- Serum bilirubin >8 mg/dL
- Progressive encephalopathy
- Renal failure
- Presence of ascites
- Maddrey's discriminant function >32.

$$\text{Lille Model Score} = (\exp(-R))/(1 + \exp(-R))$$

Where R = 3.19 – 0.101 (age, years) + 0.147* (albumin day 0, g/L) + 0.0165* (evolution in bilirubin level, μmol/L) – 0.206* (renal insufficiency) – 0.0065* (bilirubin day 0, μmol/L) – 0.0096* (PT, seconds).*

The score was found to be highly predictive of death at 6 months. Scores under 0.45: estimated 6-month mortality rate is ~25%. Scores above 0.45: estimated 6-month mortality is likely over 85%.

Treatment

- It is advised to stop alcohol consumption for life, because this is a precirrhotic condition.
- Severe hepatitis needs bed rest.
- Nutrition: Feeding via a fine-bore nasogastric tube or sometimes intravenously (>3,000 kcal/day; multivitamins mainly vitamins B and C).

- Treatment for encephalopathy and ascites
- Corticosteroids (prednisolone) may be tried in severe cases (discriminant function >32) in the absence of any infection. Based on the Lille scores, patients can be categorized into a full responder, partial responder, and non-responder having a Lille score of ≤0.16, 0.16–0.56, and >0.56, respectively.
- Pentoxifylline in severe cases (discriminant function >32). PTX is a non-phosphodiesterase inhibitor that possesses anti-inflammatory properties, inhibits TNF-α production, and has anti-fibrogenic properties
- N-acetylcysteine (NAC) is an antioxidant that neutralizes free radicals by increasing the intracellular glutathione and counteracting oxidative stress and inflammation protecting cells from damage
- Antimicrobial therapies for the treatment of bacterial (ceftazidime + meropenum + daptomycin) and fungal infections (voriconazole, liposomal amphotericin B, and echinocandins)
- Stem-cell-based therapies-umbilical-cord-derived mesenchymal stem cells (MSCs), allogenic ABCB5-positive MSCs and HepaStem cells migrate to the liver through circulation where they perform various functions including the downregulation of proinflammatory response, inhibition of hepatic stellate cell (HSC) activation, and reduction of collagen secretion, ultimately reducing fibrosis
- Granulocyte-colony stimulating factor therapy
- Liver transplantation remains the ultimate therapy for patients with ACLF who face unsuccessful medical treatment.

CIRRHOSIS

Q. LIst the causes of cirrhosis.

Q. IM5.6 Describe and discuss the pathophysiology, clinical evolution and complications of cirrhosis and portal hypertension including ascites, spontaneous bacterial peritonitis, hepatorenal syndrome and hepatic encephalopathy.

Q. Discuss the pathology, pathogenesis, classification, clinical features, investigations, complications and treatment/ management of cirrhosis.

Definition

Cirrhosis is an **end-stage** of any chronic liver disease. It is a **diffuse process** (entire liver is involved) characterized by **fibrosis** and conversion of normal architecture to structurally **abnormal regenerating nodules** of liver cells. The three main morphologic characteristics of cirrhosis are: (1) **fibrosis, (2) regenerating nodules,** and (3) **loss of architecture** of the **entire liver**.

TABLE 6.27: Morphological classification of cirrhosis.

Micronodular cirrhosis (Laennec's cirrhosis)	***Macronodular cirrhosis***
➢ Regular, small nodules < 3 mm ➢ Uniform thin regular fibrous connective tissue septa ➢ Involvement of every lobule of whole liver ➢ Most common cause: Alcoholic cirrhosis	➢ Irregular, coarse nodules of variable size >3 mm ➢ Fibrous connective tissue septa, broad, vary in thickness. Liver surface is grossly distorted ➢ Most common cause: Chronic viral hepatitis ➢ Increased risk of developing carcinoma of liver
Mixed cirrhosis	
Both micronodular and macronodular cirrhosis	

Classification

Morphological classification (**Table 6.27 and Fig. 6.11**)

Etiological Classification

Main causes of cirrhosis are listed in **Box 6.13**.

Pathology and Pathogenesis of Cirrhosis

- Chronic injury to the liver results in inflammation and **widespread necrosis of liver cells** and, eventually, **fibrosis**. Fibrosis is due to **activation of the stellate cells (in the space of Disse) by many cytokines** and their receptors, reactive oxygen intermediates, and other paracrine and autocrine signals. TGF-β is the most potent fibrogenic mediator.
- Cirrhotic changes affect the **whole liver**, but not necessarily every lobule.
- **Extensive fibrosis** that distorts and results in loss of liver architecture.

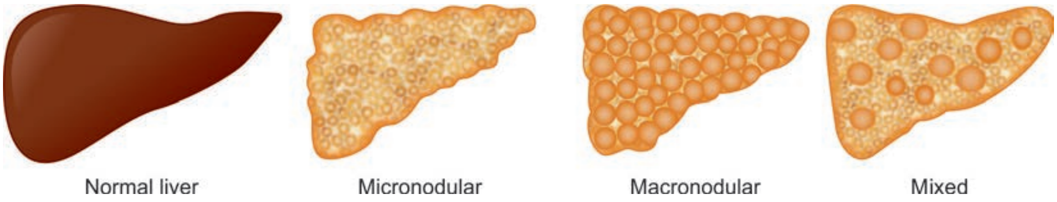


FIG. 6.11: Morphological classification of cirrhosis.

- **Regenerating nodules** are produced due to hyperplasia of the remaining surviving liver cells.
- **Destruction and distortion of hepatic vasculature** by fibrosis lead to obstruction of blood flow. Vascular reorganization leads to portal hypertension and its sequelae (gastroesophageal varices and splenomegaly).
- **Ascites and hepatic encephalopathy** develop due to hepatocellular insufficiency and portal hypertension.
- Hepatocellular damage produces jaundice, edema, coagulopathy, and a various metabolic abnormalities.

Alcoholic Cirrhosis

- Safe limits of alcohol are 200 g (20–40 g/day) in males and 140 g (16–30 g/day) in females of alcohol per week. Intake of 180 g of alcohol/day for 25 years increases the risk of cirrhosis by 25 times.
- Development of cirrhosis is six-fold when alcohol consumption is double the safety limit.
- Hepatitis C infection is an important contributory factor for progression to cirrhosis.
- Pathogenesis of alcoholic cirrhosis (**Fig. 6.12**).

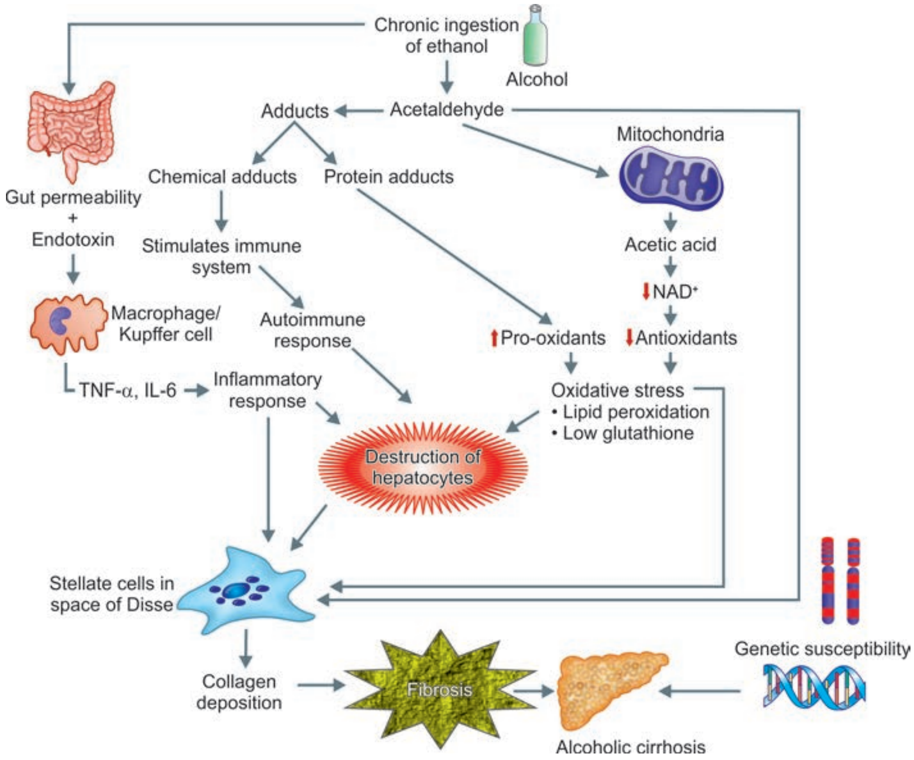
Clinical Features

Q. Write the clinical features of alcoholic cirrhosis.

Box 6.13: Main causes of cirrhosis.

- Alcohol (one of the most common causes)
- Chronic viral hepatitis (most common cause)
    - Hepatitis B
    - Hepatitis C
    - Delta hepatitis (hepatitis D) + hepatitis B
- Nonalcoholic steatohepatitis (NASH) or nonalcoholic fatty liver disease (NAFLD) (earlier was considered as cryptogenic cirrhosis)
- Biliary cirrhosis
    - Primary biliary cholangitis
    - Secondary biliary cirrhosis
    - Primary sclerosing cholangitis
    - Autoimmune cholangiopathy, IgG4 cholangiopathy
- Autoimmune hepatitis
- Budd–Chiari syndrome
- Intrahepatic or extrahepatic biliary obstruction: Recurrent biliary obstruction (e.g., gallstones)
- Inherited metabolic liver disease
    - Hemochromatosis
    - Wilson's disease
    - α1 antitrypsin deficiency
    - Cystic fibrosis
    - Glycogen storage disease
- Drug-induced cirrhosis: For example, methotrexate, methyldopa, isoniazid, phenylbutazone, sulfonamides
- Others: Indian childhood cirrhosis, cardiac cirrhosis, chronic venous outflow obstruction, celiac disease

Hereditary hemo-telangiectasia, infection [e.g., brucellosis, syphilis, echinococcosis, porphyria, idiopathic adulthood ductopenia (Caroli disease)]



Chronic ingestion of ethanol
Alcohol
Acetaldehyde
Adducts
Chemical adducts
Protein adducts
Mitochondria
Gut permeability
+
Endotoxin
Stimulates immune system
Acetic acid
↓NAD+
Macrophage/ Kupffer cell
Autoimmune response
↑Pro-oxidants
↓Antioxidants
TNF-α, IL-6
Inflammatory response
Oxidative stress
• Lipid peroxidation
• Low glutathione
Destruction of hepatocytes
Stellate cells in space of Disse
Genetic susceptibility
Collagen deposition
Fibrosis
Alcoholic cirrhosis

FIG. 6.12: Pathogenesis of alcoholic liver disease.

Symptoms

- **Highly variable** and in some patients it may be completely asymptomatic and is incidentally diagnosed at ultrasound or at surgery.
- **Nonspecific symptoms:** Weakness, fatigue, muscle cramps, weight loss, anorexia, nausea, vomiting, and upper abdominal discomfort.
- **Symptoms of hepatic insufficiency**
- **Symptoms of portal hypertension and its sequelae**
- **Symptoms due to endocrine changes:**
  - Loss of libido, hair loss
  - *Females:* Irregular menses, amenorrhea, and atrophy of breast
  - *Males:* Gynecomastia, testicular atrophy, and impotence.
- **Hemorrhagic tendencies:** Due to decreased production of coagulation factors by the liver and thrombocytopenia resulting from hypersplenism. These include easy bruising, purpura, epistaxis, menorrhagia, and GI bleeding.

Signs

Summary of signs of cirrhosis of liver is given in **Table 6.28**.

TABLE 6.28: Summary of signs of cirrhosis of liver.

Signs	*Symptoms*
➢ Jaundice ➢ Hepatomegaly/shrunken liver ➢ Ascites ➢ **Circulatory changes:** Spider nevi, palmar erythema ➢ **Endocrine changes:** Loss of libido, diminished body hair and hair loss, gynecomastia, testicular atrophy, impotence in males, irregular menses, amenorrhea breast atrophy in females. ➢ **Hemorrhagic tendency:** Bruises, purpura, and epistaxis ➢ **Portal hypertension:** Splenomegaly, portosystemic collateral vessels, variceal bleeding ➢ Flapping tremors ➢ Pigmentation, clubbing, cyanosis, white nails, Muehrcke's nails Dupuytren's contracture, parotid enlargement	➢ Asymptomatic, diagnosed at ultrasound ➢ **Nonspecific:** Weakness, fatigue, muscle cramps, weight loss, anorexia, nausea, vomiting, upper abdominal discomfort ➢ **Hepatic insufficiency** ➢ **Portal hypertension, sequelae** ➢ **Endocrine changes:** Males: gynecomastia, loss of libido, hair loss; Females: Irregular menses, amenorrhea, breast atrophy ➢ **Hemorrhagic tendency:** Easy bruising, purpura, epistaxis, menorrhagia and gastrointestinal bleeding

Jaundice

- Jaundice is **not a common** feature of cirrhosis; it is more common with acute diseases.
- Mechanisms of jaundice in cirrhosis:
  - Failure to excrete bilirubin (mainly)
  - Intrahepatic cholestasis (superadded hepatitis/tumor)
  - Hemolysis due to hypersplenism (not a major contributor)

Hepatomegaly

- **Early stages: Liver is enlarged**, firm to hard, irregular, and nontender. Hepatomegaly is **not common** in cirrhosis but common when the cirrhosis is due to alcoholic liver disease, NASH, and hemochromatosis. Hepatomegaly may indicate transformation into HCC.
- **Late stages: Liver decreases in size** and nonpalpable due to progressive destruction of liver cells and accompanying fibrosis.

Ascites

Ascites due to liver failure and portal hypertension signify advanced disease.

Circulatory changes

1. **Spider nevi (Fig. 6.13)** (spider telangiectasia, vascular spiders, spider angiomas, arterial spiders).
   - **Appearance:** Consists of a central arteriole from which numerous small vessels radiate peripherally-resembling spider's legs. Whole spider disappears when central arteriole is compressed with a pinhead. When compression is released filling occurs from center to periphery.

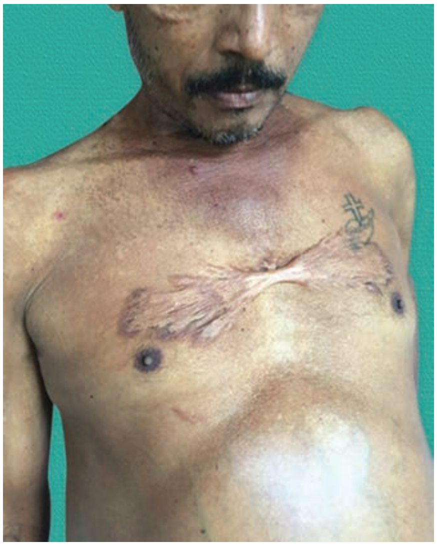


FIG. 6.13: Cirrhosis of liver with ascites and spider nevi. Patient in addition has tattoo and keloid, which may suggest viral hepatitis as the cause of cirrhosis.

TABLE 6.29: Conditions associated with spider nevi.

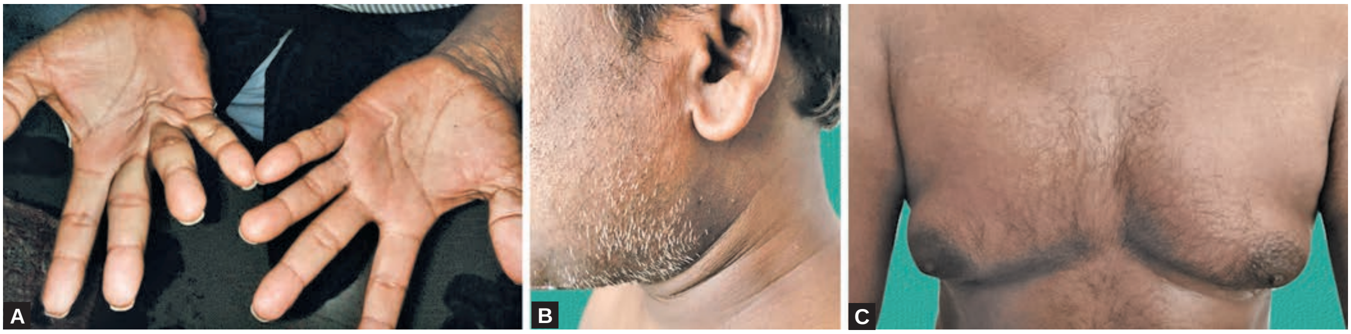
Liver disorders	*Others*
Viral hepatitis	2% of healthy individuals
Alcoholic hepatitis	Third trimester of pregnancy
Hepatocellular carcinoma	Rheumatoid arthritis
Treatment with Sorafenib	Thyrotoxicosis

- **Cause:** Due to arteriolar changes induced by hyperestrogenism.
- **Sites affected:** Usually found only in the necklace area, i.e., above the nipples, territory drained by the superior vena cava such as head and neck, upper limbs, front and back of upper chest. Most probable cause of location in the superior vena cava drainage area in that maximum blood in the portal circulation that cannot go through the liver due to fibrosis reach the systemic circulation through the SVC.
    - **Size:** Varies from pinhead to 0.5 mm in diameter.
- **Significance:** They are a strong indicator of liver disease but can be found in other conditions (**Table 6.29**).
    - Florid spider telangiectasia, gynecomastia, and parotid enlargement are most common in alcoholic hepatitis.
    - Florid spiders and new-onset clubbing in a patient with cirrhosis indicate hepatopulmonary syndrome.
    - Differential diagnosis for spider nevi includes *venous star,* Campbell de Morgan spots, petechiae, and hereditary hemorrhagic telangiectasias.

2. **Palmar erythema (liver palm) (Fig. 6.14A)**
    - Can be seen early but is of limited diagnostic value, as it occur in many conditions associated with a hyperdynamic circulation (e.g., normal pregnancy).
    - **Cause:** Develops due to increased peripheral blood flow. In cirrhosis, circulatory changes results in increased peripheral blood flow and decreased visceral blood flow (especially to the kidneys).
    - **Sites involved:** Prominent in the thenar and hypothenar eminences of palm. May be seen on the sole.

Endocrine changes

- **Diminished body hair and loss of hair (Fig. 6.14B)**
    - Seen mainly in males with loss of male hair distribution
    - Alopecia affects usually the face, axilla, and chest and is due to hyperestrogenism
    - *Causes of hyperestrogenism:* Due to increased peripheral formation of estrogen resulting from diminished hepatic clearance of the precursor, androstenedione.
    - *Effects of hyperestrogenism:* Alopecia, gynecomastia, and testicular atrophy.
- **Hyperglycemia: 80%** of cirrhotics have impaired glucose tolerance, 20% develop diabetes.



FIGS. 6.14A TO C: Features of cirrhosis. (A) Palmar erythema with Dupuytren's contracture; (B) Diminished facial hair with parotid enlargement; (C) Gynecomastia.

In Males

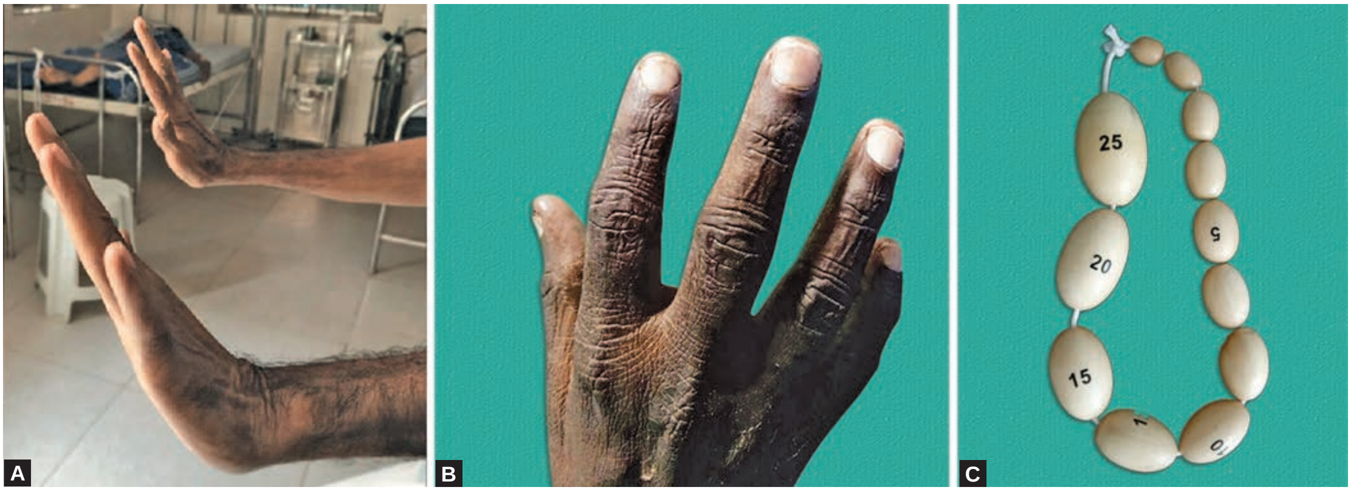
- **Gynecomastia (Fig. 6.14C)**
    - Found in males (atrophy of breasts in females).
    - Cause: Due to increased estradiol/free testosterone ratio.
    - Causes of gynecomastia are listed in **Table 6.30**.
    - Appear as palpable nodule (4 cm, subareolar). Microscopy: Proliferation of glandular tissue of breast.

    Pseudogynecomastia is accumulation of subareolar fat tissue without palpable nodule.

TABLE 6.30: Cause of gynecomastia.

Cirrhosis of liver	
Drugs:	
Spironolactone	Physiological (puberty/aging)
Cimetidine	Klinefelter syndrome
Digoxin	Hypogonadism
Ketoconazole	Tumor
Estrogens	– Testes
Isoniazid	– Lung

- **Testicular atrophy:** Due to hyperestrogenic state, it is characterized by a small size compared with Prader orchidometer **(Fig. 6.14C)**—soft testes with loss of testicular sensation (sickening sensation in epigastrium on squeezing the testes). The dimensions of the average adult testicle is 4.5 × 3.5 × 2.5 cm and the volume is 15–25 mL.



FIGS. 6.15A TO C: (A) Flapping tremor; (B) White nails; (C) Prader orchidometer.

In Females

Irregular menses, amenorrhea, and atrophy of breast.

Flapping tremors (Fig. 6.15A): Observed in hepatic precoma (refer to hepatic encephalopathy).

Other features

- **Generalized skin hyperpigmentation:** Due to increased melanin deposition
- **Dupuytren's contracture (Fig. 6.13A)—sign of alcoholism**
  - **Cause:** Fibrosis of palmar aponeurosis is probably caused by local microvessel ischemia. Platelet and fibroblast-derived growth factors promote fibrosis.
  - **Sites involved:** Flexion contracture of the fingers (especially ring and little fingers)
  - **Other causes** of Dupuytren's contracture: Diabetes mellitus, rheumatoid arthritis, and manual labor (workers exposed to repetitive handling tasks or vibration).
- **Clubbing and central cyanosis:** Due to development of pulmonary arteriovenous shunts that lead to hypoxemia
- **Nail changes**
  - White (Terry's) chalky (**Fig. 6.15B**) and brittle nails
  - Muehrcke's nails: Characterized by transverse white lines that disappear on applying pressure and these lines do not move with growth of nail.
  - Clubbing is present in PBC or hepatoma
- **Parotid and lacrimal gland enlargement:** Observed commonly in alcoholic cirrhosis due to associated autonomic dysfunction.
- **Anemia:** Due to various causes **(Box 6.14)**

Box 6.14: Causes of anemia in cirrhosis.

- Acute and chronic blood loss from varices
- Nutritional deficiency of vitamin B_{12} and folate
- Hypersplenism
- Bone marrow suppression by alcohol
- Hemolysis
- Zeive's syndrome: Alcohol-induced hemolytic anemia with hypercholesterolemia

SIGNS POINTING THE ETIOLOGY OF CIRRHOSIS

Signs	***Etiology of Cirrhosis***
Parotid enlargement, Dupuytren's contracture	**Alcohol**
Tattoo marks, jaundice	**Hepatitis B/C**
Metabolic syndrome	**NASH**
Xanthoma, xanthelasma, obstructive jaundice	**Primary biliary cirrhosis**
Association with inflammatory bowel disease	**Primary sclerosing cholangitis**
Skin hyperpigmentation, organomegaly, diabetes	**Hemochromatosis**
Emphysema and cirrhosis	**Alpha-1 antitrypsin deficiency**
Longstanding right-sided heart failure, constrictive pericarditis, mitral stenosis, tricuspid regurgitation, cor pulmonale, cardiomyopathy	**Cardiac cirrhosis**
Tender liver with absent abdominojugular reflux	**Budd–Chiari**
Arthritis, skin changes, nephritis	**Autoimmune**
Deforming arthritis on treatment	**Methotrexate induced**
Kayser–Fleischer (KF) ring on cornea, young onset, family history +	**Wilson's disease**

Symptoms and Signs due to Complications

Q. List the complications/life-threatening complications of cirrhosis of liver.

Three major complications of cirrhosis **(Table 6.31)** are:

1. **Portal hypertension:** Splenomegaly and collateral vessel formation are features of portal hypertension develops in advanced disease.
2. **Hepatic encephalopathy**
3. **Renal failure.**

TABLE 6.31: Complications of cirrhosis.

Portal hypertension and its sequelae (variceal hemorrhage)	Hepatorenal syndrome	Hepatocellular carcinoma
Ascites	Portal gastropathy	Portal vein thrombosis
Spontaneous bacterial peritonitis	Hepatopulmonary syndrome	Cirrhotic cardiomyopathy
Hepatic encephalopathy	Hepatic hydrothorax	Portopulmonary hypertension
Coagulopathy, thrombocytopenia, and hyponatremia	Endocrine dysfunction—adrenal insufficiency, gonadal dysfunction, thyroid dysfunction	Cirrhotic osteodystrophy
Nutritional disorders—protein-energy malnutrition nutritional deficiencies of vitamins, trace elements, and polyunsaturated fatty acids	Infections	

Extrahepatic Manifestations

1. **Pleural effusion (hepatic hydrothorax):**
   - It is transudate. Often associated with ascites.
   - In about 13% of patients with cirrhosis, fluid in the pleural space can be detected on chest radiographs.
   - It is usually right sided (66%) but may be bilateral (17%) or left sided (17%)
   - **Mechanisms:**
     - Hypoalbuminemia causes decreased colloid osmotic pressure.
     - Leakage of ascitic fluid may occur through diaphragmatic defects.
     - Transdiaphragmatic migration of fluid via lymphatic channels.

Treatment: It includes control of ascites, transjugular intrahepatic portosystemic shunt, video-assisted thoracoscopy with pleurodesis, video-assisted thoracoscopy with repair of defects in the diaphragm and liver transplantation.

2. **Hepatopulmonary syndrome**
   - The triad of liver dysfunction, intrapulmonary vasodilation and arterial oxygenation defect is used to define hepatopulmonary syndrome (HPS)
   - The prevalence varies from 10% to 17% in the cirrhotic population and is associated with increased mortality
     - **Cause:** Hypoxemia is due to intrapulmonary vascular vasodilation without any evidence of primary pulmonary disease.
     - Patients show features of cirrhosis with **spider nevi, clubbing, and cyanosis**.
     - **Symptoms:** Most patients have no respiratory symptoms but with more severe disease complain of insidious onset of breathlessness on standing **(orthodeoxia–platypnea)**.
     - **Investigations:**
       - Chest X-ray: May show a bibasilar interstitial pattern that reflects the predominantly basal vascular dilatations.
       - Transthoracic ECHO: Shows intrapulmonary shunting.
       - Arterial blood gases: Confirm the arterial oxygen desaturation.
       - The diagnosis is confirmed by 2-dimensional contrast echocardiography and technetium Tc 99m–labeled macroaggregated albumin lung scanning. Contrast-enhanced (microbubble) echocardiography, perfusion lung scan, and pulmonary angiography can be done.

Treatment: Oxygen inhalation and coil embolization (in localized shunts).

Liver transplantation—patients with severe hypoxemia (PaO_2, 50 mm Hg or lower) due to the hepatopulmonary syndrome and advanced liver disease should be considered for liver transplantation.

3. **Portopulmonary hypertension:**
   - Portopulmonary hypertension (PPHTN) is a well-recognized complication of cirrhosis. It is defined as pulmonary hypertension (PAH) (mean pulmonary artery pressure >25 mm Hg and pulmonary capillary wedge pressure <15 mm Hg) in a patient with coexisting portal hypertension and no other alternative cause of PAH
   - Dyspnea on exertion is the most common symptom and can lead to right heart failure.
   - These are at increased risk of pulmonary vascular thrombosis, hence it is reasonable to start these patients on anti-coagulation drugs, if there are no contraindications.
   - Other agents that have been used to treat PPHTN include epoprostenol, bosentan, sildenafil, and iloprost
4. **Cirrhotic cardiomyopathy:** Characterized by systolic and diastolic dysfunction, electrophysiological changes, and gross and microscopic structural changes.
5. **Hepatic osteodystrophy:** Osteoporosis and osteomalacia.

Table 6.32 shows noninvasive direct and indirect markers of hepatic fibrosis.

Prognostic Classifications

Q. Write short note on Child–Pugh score or Child–Turcotte–Pugh score.

The Child–Pugh (CP) scoring classification was originally used to risk-stratify patients undergoing shunt surgery. Modifications of Child's–Pugh grading (A, B, and C)/Child–Turcotte–Pugh score is shown in **Table 6.33** and is useful to grade the **severity of liver disease and prognosticate** patients with established cirrhosis. Other scoring system used is **The Model for End-stage Liver Disease (MELD)** which bilirubin, creatinine, and INR for prothrombin time to predict 3-month survival.

$$MELD = 3.8 \times \log_e(\text{serum bilirubin [mg/dL]}) + 11.2 \times \log_e(\text{INR}) + 9.6 \times \log_e(\text{serum creatinine [mg/dL]}) + 6.4$$

TABLE 6.33: Modified Child's–Pugh classification or Child–Turcotte–Pugh (CTP) score.

	Score		
Parameter	***1***	***2***	***3***
Encephalopathy	None	Mild	Marked
Ascites	None	Mild or controlled with diuretics	Moderate/ severe
Prolongation of prothrombin time (seconds over normal)	<4	4–6	>6
Serum albumin (mg/dL)	>3.5	2.8–3.5	<2.8
Serum bilirubin (mg/dL)	<2	2–3	>3

CTP class A: Points 5–6; CP class B: 7–9; CP class C: > 9 (range 5–15) 1-year survival rates for patients with Child–Pugh class A, B, and C cirrhosis are approximately 100, 80, and 45%, respectively.

Characteristics of end-stage of cirrhosis **(Box 6.15)**.

Box 6.15: Characteristics of end-stage of cirrhosis.

- Jaundice
- Progressive, refractory ascites
- Worsening of signs of portal hypertension
- Progressive renal dysfunction hepatic encephalopathy

Poor Prognostic Factors in Cirrhosis

See **Table 6.34**

TABLE 6.32: Noninvasive direct and indirect markers of hepatic fibrosis.

Direct markers	
Procollagen type I carboxy terminal peptide (PICP), procollagen type III amino-terminal peptide (PIIINP)	Metalloproteinases (MMPs), tissue inhibitors of matrix metalloproteinases (TIMPs), hyaluronic acid
Indirect serum markers of liver fibrosis	
Indices	**Individual components**
AST/ALT ratio	Aspartate aminotransferase, alanine aminotransferase
PGA	Prothrombin index, GGT, apolipoprotein A1
APRI	AST/platelet count
FibroSpect II	HA, TIMP-1, α2-macroglobulin
FibroTest/FibroSure	γ2 macroglobulin, γ2 globulin, γ globulin, apolipoprotein A1, GGT, total bilirubin
FibroIndex	Platelet count, AST, GGT
FibroMeter	Platelet count, γ2 macroglobulin, AST, age, prothrombin index, HA, blood urea nitrogen
Hepascore	Age, gender, bilirubin, GGT, HA, γ2-macroglobulin
FIB-4	Platelet count, ALT, AST, platelet count, age

(ALT: Alanine aminotransferase; APRI: AST/platelet ratio index; AST: Aspartate aminotransferase; GGT: Gamma-glutamyl transpeptidase; HA: Hyaluronic acid; TIMP-1: TIMP metallopeptidase inhibitor 1)

TABLE 6.34: Poor prognostic factors in cirrhosis.

Laboratory findings	***Clinical findings***
➢ Low serum albumin of <2.5 g/dL ➢ Low serum sodium of <120 mmol/L ➢ Rising serum creatinine ➢ Prolongation of prothrombin time more than 1.5 times of control (>6 seconds above normal)	➢ Persistent jaundice (serum bilirubin >20 mg/dL) ➢ Ascites responding poorly to therapy ➢ Encephalopathy not associated with an extensive collateral circulation ➢ Hemorrhage from varices with poor liver function ➢ Neuropsychiatric complications ➢ Persistent hypotension ➢ Small liver ➢ Etiology (e.g., hepatitis C, alcoholic cirrhosis, if the patient continues drinking)

Investigations

Investigations are helpful for assessing the severity and type of liver disease.

Liver Function Tests

- **Hyperbilirubinemia:** Due to rise in both conjugated and unconjugated bilirubin. Not very common with cirrhosis. It could suggest superadded hepatitis, hepatocellular carcinoma, congestive or obstructive etiology.
- **Serum proteins:** Show **reversal of A:G ratio.**
  - **Serum albumin is decreased** (hypoalbuminemia) and is due to reduced synthesis by liver.
  - **Serum globulin is increased** (hyperglobulinemia) due to stimulation of reticuloendothelial system.
- **Serum transaminases**
  - **AST (SGOT) is raised.**
  - **ALT (SGPT) is raised** and usually less than 300 units/dL.
  - **AST:ALT ratio**
    - More than 2 in alcoholic cirrhosis.
    - Less than 2 in cirrhosis complicating viral hepatitis.

- **ALP:** It may be slightly elevated.
- **Prothrombin time: Prolonged** due to reduced synthesis of clotting (especially vitamin K-dependent) factors.

Hematological Tests

Peripheral blood picture

- **Anemia and acanthocytosis** (spur-like projections on RBC).
- **Leukopenia and thrombocytopenia** (due to hypersplenism and bone marrow suppression by alcohol).

Serological markers: For hepatitis B and C.

Other Biochemical Markers

- Serum electrolytes:
  - Low sodium (hyponatremia) indicates severe liver disease and is due to either defect in free water clearance or to excess diuretic therapy.
  - Hypokalemia, hypomagnesemia, and hypophosphatemia
- **Blood ammonia** estimation: It is a reliable investigation when hepatic encephalopathy is suspected. Raised blood ammonia is due to:
  - Decreased clearance by liver
  - Shunting of portal venous blood to systemic circulation
- Respiratory alkalosis: It may develop due to central hyperventilation.
- Glucose intolerance.

Imaging

Q. IM5.13 Enumerate the indications for ultrasound and other imaging studies and describe the findings in liver disease.

- **Ultrasound examination** can demonstrate features listed in **Table 6.35**.

TABLE 6.35: Most commonly observed signs of cirrhosis on imaging.

Liver morphology changes	Nodular liver surface (all imaging methods, but better visualized by high-frequency probe on ultrasound)
	Coarse echo pattern (ultrasound); heterogeneous density with nodular pattern in some cases (CT)
	Hypertrophy of the left lobe and atrophy of the segment IV (better visualized on CT and MRI); expanded gallbladder fossa (CT and MRI)
	Hypertrophy of caudate lobe
	Reduction of the medial segment of left hepatic lobe
Hepatic veins	Narrowing and loss of normal plasticity of flow by Doppler
	Altered straightness
	Nonuniformity of hepatic vein-wall echogenicity
Hepatic artery	Increased diameter (all techniques) and tortuosity (CT)
Portal venous system	Dilatation of portal vein (≥13 mm), splenic vein and superior mesenteric vein (≥11 mm)
	Reduction of portal vein blood-flow velocity
	Reversal of portal vein blood flow
Spleen	Increased size (splenomegaly: diameter >12 cm and/or area ≥45 cm^2 by ultrasound)
Presence of portosystemic collateral circulation	
Ascites	

- **CT scan/MRI:** To detect hepatosplenomegaly and dilated collaterals. Arterial phase-contrast-enhanced scans to detect HCC. Other noninvasive markers to detect hepatic fibrosis are Hepascore, FIB-4 index, Fibroindex, AST to platelet ratio, etc.
- **Hepatic venous pressure gradient (HVPG):** It is measured through internal jugular vein, femoral vein or cubital vein access under local anesthesia. One of the hepatic veins is catheterized with a balloon catheter under fluoroscopic control. By the inflation of the balloon, the hepatic venous outflow is blocked and, at the end of 1–2 minutes, the pressure at the tip of the catheter equals that of the hepatic sinusoidal pressure and portal pressure, respectively. That represents the wedge hepatic venous pressure (WHVP). Free hepatic venous pressure (FHVP) is measured by deflating the balloon at 2–3 cm from the hepatic vein ostium, and usually its value is very close to the inferior vena cava. **HVPG is the difference between WHVP and FHVP**, and represents the pressure gradient that the portal blood flow has to exceed to pass through the liver.

- *Different thresholds of hepatic venous pressure gradient (HVPG) correlated with clinical end-points in compensated advanced chronic liver disease (cACLD)* **(Table 6.36).**
- ***Endoscopy*** for detecting and treating varices and portal hypertensive gastropathy. Barium swallow may also be useful for demonstration of varices.

Hepatic Elastography

Q. Write short note on hepatic elastography.

- Hepatic fibrosis represents an early stage of chronic liver disease and cirrhosis.
- Conventional liver tests and imaging studies are not sensitive for detecting hepatic fibrosis.

TABLE 6.36: Correlation of HVPG and clinical outcomes.

HVPG	***Clinical end-points***
<5 mm Hg	**Normal**
5–10 mm Hg	**Mild portal hypertension**
>6 mm Hg	Progression of chronic viral hepatitis
	High-risk of recurrence after liver transplantation
>10 mm Hg	**Clinically significant portal hypertension**
>10 mm Hg	Esophageal varices development
	Ascites
	Decompensation
	Hepatocellular occurrence
	Decompensation after hepatic resection
>12 mm Hg	Esophageal varices bleeding
>16 mm Hg	High mortality
>20 mm Hg	Failure to control bleeding
>22 mm Hg	High mortality in severe alcoholic hepatitis

FIG.6.16: Natural history of diagnostic of liver disease and non-invasive diagnostic tests.

- Hepatic elastography is a noninvasive method **for measurement of hepatic fibrosis**.
- Methods used are ultrasound and MRI [acoustic radiation force impulse (ARFI) imaging, real-time shear wave elastography (SWE)].
- Methods for performing SWE, including transient elastography, point-SWE, and two-dimensional (2D)-SWE.
- Ultrasound-based elastography is primarily used to assess hepatic fibrosis, it can also be used to predict complications in patients with cirrhosis-like development of large varices and HCC.

Transient elastography	➢ Available in most centers ➢ Easy to perform and reproducible ➢ Validated in most etiologies (AUC ~90% for cirrhosis and for CSPH; ~80% for varices)	➢ Applicability of liver-stiffness measurement in obese patients is suboptimal unless XL probe is used ➢ False positives can occur (inflammation, infiltration, congestion, cholestasis, food intake) ➢ Spleen-stiffness measurement is possible only in patients with splenomegaly
Point shear-wave elastography	➢ Easy to perform and reproducible ➢ Validated for cirrhosis	Not available in many centers
	Allow the measurement of spleen stiffness with higher applicability as compared to transient elastography	
2D shear-wave elastography	➢ Validated for cirrhosis ➢ Visualization of pattern and measurement of fibrosis in larger areas in real time	

Liver Biopsy

See **Box 6.16.**

Special investigations depending on the etiology:

- Chemical measurement of iron (serum transferrin saturation level and serum ferritin) and copper (ceruloplasmin) are required to confirm diagnosis of iron overload or Wilson's disease.
- *Others:* Serum α-fetoprotein, α_1-antitrypsin, antinuclear antibodies and anti-smooth muscle antibodies, etc., depending on the etiology.

Box 6.16: Usefulness of liver biopsy in cirrhosis.

- To confirm the diagnosis of cirrhosis
- Assesses the severity and type of liver disease

The Laennec sub-classification of cirrhosis in three subclasses of stage 4: 4A—mild cirrhosis with thin septa and large nodules; 4B—at least two broad septa, but no very broad septa and less than half of biopsy length composed of minute nodules; 4C—very broad septum or more than half of biopsy length composed of minute nodules (micronodular cirrhosis) offers additional prognosis relevance

- **Special stains:** They may be necessary for iron and copper
- **Immunocytochemical stains:** They can identify viruses.

Ascitic Fluid Examination (Discussed Later)

Investigations for the etiology of cirrhosis: Even in a patient of cirrhosis with chronic consumption of alcohol, rule out other causes (viral serology, etc.) as only 15–18% of alcoholics develop cirrhosis.

Management (Treatment)

- There is **no treatment available to arrest or reverse the cirrhotic changes** in liver. **Liver transplantation** is the specific treatment.
- Progression may be halted by correcting the underlying cause, removal of causative agents such as drugs and alcohol.
- **Diet:**
  - High-protein diet: Minimum 1 g/kg/day; 2,000–3,000 kcal/day
  - Diets with branched-chain amino acids in patients predisposed to hepatic encephalopathy
  - Multivitamin supplements
  - Reduce salt intake
- Avoidance of aspirin, NSAIDs, and other hepatotoxic drugs.
- **Management of the complications:** Specific treatment of complications, e.g., variceal bleeding, hepatic encephalopathy, and ascites (discussed separately).
- **Follow-up:** With 6-monthly ultrasound and serum α-fetoprotein measurements for early detection of development of HCC.

PORTAL HYPERTENSION

Q. IM5.16 **Describe and discuss the management of hepatitis, cirrhosis, portal hypertension, ascites spontaneous, bacterial peritonitis and hepatic encephalopathy.**

Portal vein is formed by the union of the superior mesenteric and splenic veins. Normally, the pressure within portal vein is 5–8 mm Hg (or 10–15 cm saline).

Definition

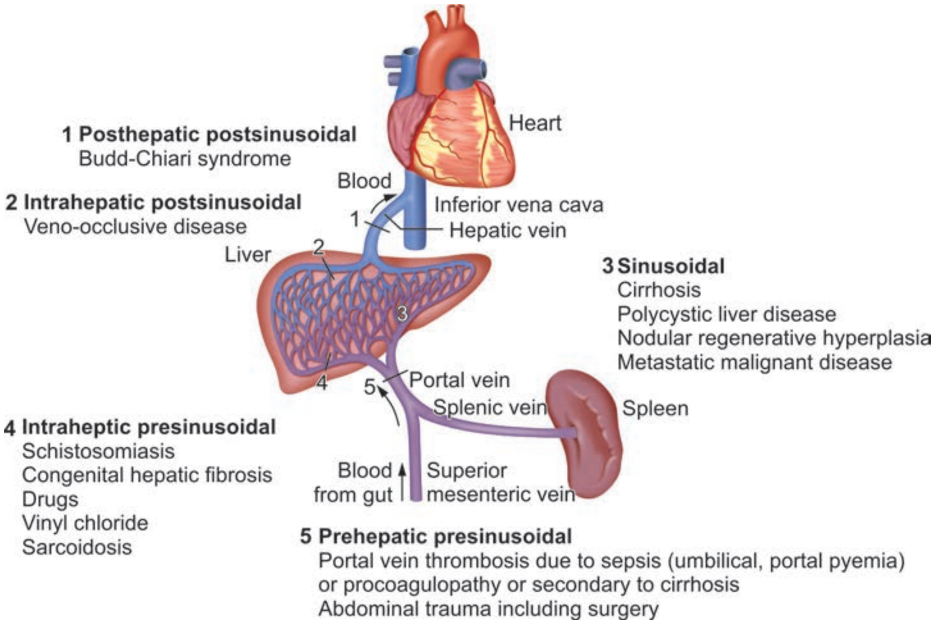
- Portal hypertension is defined as **prolonged elevation of portal venous pressure** (>30 cm saline).
- It is better defined as elevation of **hepatic venous pressure gradient** (HVPG-difference in pressure between portal vein and hepatic vein) more than 7 mm Hg. HVPG more than 10 mm Hg defines significant portal hypertension/clinically significant portal hypertension (CSPH).
- Above this critical threshold of 10 mm Hg, patients with CSPH are at an increased risk of developing gastroesophageal varices, overt clinical decompensation (ascites, variceal hemorrhage [VH], and hepatic encephalopathy [HE]), postsurgical decompensation, and hepatocellular carcinoma.

Classification of Portal Hypertension (Fig. 6.17)

Q. Define and classify portal hypertension.

Portal hypertension can be classified according to the site of obstruction into **prehepatic, intrahepatic, and posthepatic**.

- **Prehepatic causes:** Obstruction/blockage of the portal vein before it ramifies within the liver, e.g., portal vein thrombosis, splenic vein thrombosis, and massive splenomegaly (Banti's syndrome).
- **Intrahepatic causes***:* Due to distortion of the liver architecture and may be further divided into:
  - **Presinusoidal** (e.g., in schistosomiasis)
  - **Sinusoidal** (e.g., in cirrhosis)
  - **Postsinusoidal** (e.g., hepatic sinusoidal obstruction—veno-occlusive syndrome).



1 Posthepatic postsinusoidal
Budd-Chiari syndrome
2 Intrahepatic postsinusoidal
Veno-occlusive disease

Portal: Superior rectal vein
Systemic: Middle/inferior rectal veins
Hemorrhoids

FIG. 6.18: Consequences of portal hypertension with sites of portosystemic anastomosis in cirrhosis.

Pathogenesis of Portal Hypertension (Fig. 6.18)

Q. Discuss the etiology, pathogenesis, clinical features, investigations, complications and management of portal hypertension.

Portal hypertension in cirrhosis results from:

- **Increased intrahepatic resistance** to blood flow through the liver and leads to:
    - As portal pressure rises above 10–12 mm Hg, the portal venous system dilates, reduces the portal blood to the liver and collaterals occur within the systemic venous system. Development of collateral vessels allowing portal blood to bypass the liver and enter systemic circulation.
    - Initially, collateral vessel formation diverts most of the portal blood and later almost all of the entire portal blood directly to the systemic circulation, bypassing the liver.
- **Increase in portal venous inflow (flow)** resulting from the hyperdynamic circulation.

Clinical Features

Q. Write short note on clinical features and diagnosis of portal hypertension.

- Patients with portal hypertension are often asymptomatic.
- History, e.g., alcoholism, past history of hepatitis. Triad of portal hypertension consists of **ascites, splenomegaly, and dilated tortuous abdominal wall veins (Fig. 6.19).**
- **Bleeding from esophageal varices** or portal hypertensive gastropathy causes hematemesis and melena.
- **Splenomegaly:** It may be only clinical evidence and single most important diagnostic feature of portal hypertension.
    - A diagnosis of portal hypertension should not be made if there is no documentation of splenomegaly either clinically, radiographically or ultrasonography.

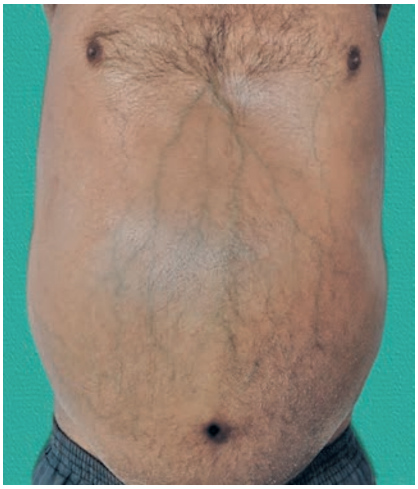

FIG. 6.19: Dilated veins over the anterior abdominal wall and ascites in cirrhosis.

  - Usually spleen is palpable less than 5 cm below costal margin. However, marked splenomegaly can be found in younger patients, those with macronodular cirrhosis and in extrahepatic portal hypertension.
  - Hypersplenism manifests as thrombocytopenia and leukopenia. Splenomegaly may disappear after massive GI bleed or shunt surgery.
- **Features due to liver cell failure/hepatic encephalopathy.**
- **Fetor hepaticus:** It is a musty odor of breath due to shunting of blood from portal system to systemic circulation that allows mercaptans to pass directly to the lungs, bypassing the liver.
- **Caput medusae**, suggestive of an intrahepatic cause of portal hypertension, are present around the umbilicus; the flow of blood is away from the umbilicus.
  - In Budd–Chiari syndrome, by contrast, veins are dilated in the flanks and back, and blood flows in a cephalic direction.
- A bruit may be heard in the left or the right upper quadrant in a patient with a splanchnic arteriovenous fistula.
- **Cruveilhier–Baumgarten syndrome:** A venous hum may be heard in the epigastrium of a patient with portal hypertension and represents collateral flow in the patent umbilical vein in the falciform ligament. A patent umbilical vein excludes an extrahepatic cause of portal hypertension because the umbilical vein arises from the intrahepatic portion of the left portal vein.
- **Rectal varices** may be confused with internal hemorrhoids because of their location. However, hemorrhoids result from a displacement of the anal cushions and hyperperfusion of the arteriovenous plexus vascular cushions without direct communication with any of the major branches of the portal venous system.
- **Liver:** It may be enlarged or shrunken.
  - **Small, contracted, fibrotic** liver is found when the portal venous pressure is very high.
  - Soft liver usually suggestive of extrahepatic portal vein obstruction.
  - Firm liver suggestive of cirrhosis and hence intrahepatic portal hypertension
- **Ascites:** It develops partly due to portal hypertension but mainly due to liver cell failure.

Investigations

The diagnosis of portal hypertension can be made on clinical grounds.

- **Barium swallow:** It shows varices as filling defects in the lower-third of esophagus (**"bag of worms appearance"**).
- **Upper GI scopy**
  - Most reliable method of investigation.
  - Esophageal varices appear as blue rounded projections (red spots and red stripes) under submucosa.
  - **"Cherry red spots" indicate impending rupture of varices**.
- **Ultrasonography** (*refer* to **Box 6.19**).
- **Portal venography** (splenoportal venogram) rarely done nowadays.
- **Measurement of portal venous pressure:** By either wedged hepatic venous pressure (WHVP) or transhepatic venous pressure. It is useful for (1) confirmation of portal hypertension, and (2) differentiating sinusoidal from presinusoidal portal hypertension.
- **Proctoscopy and barium enema:** Useful for demonstrating varices in the rectum and colon.
- **Liver function tests:** To confirm the liver diseases.

Box 6.17: Complications of portal hypertension.

- Variceal bleeding: Mainly esophageal and gastric
- Hepatic encephalopathy
- Ascites, spontaneous bacterial peritonitis (SBP)
- Hepatorenal, hepatopulmonary syndrome
- Congestive gastropathy
- Hypersplenism
- Iron-deficiency anemia

Complications of Portal Hypertension (Box 6.17)

Q. Name the drugs that are used in the reduction of portal venous pressure.

Treatment of Portal Hypertension

- Treatment of underlying disease
- Drugs used in the treatment of portal hypertension **(Box 6.18)**
- Nonselective β-blockers (propranolol, nadolol) produce vasodilatation of both splanchnic arterial bed and portal venous system. Also reduce recurrence of variceal bleed. The usual starting dose of long-acting propranolol is 40 mg once daily and that of nadolol is 20 mg once a daily. **Carvedilol** in addition to reducing portal venous inflow through nonselective beta blockade, the anti-alpha-1 adrenergic activity leads to reduced hepatic vascular tone and hepatic resistance.
- Nitrates (nitroglycerine and isosorbide dinitrate) along with β-blockers reduce the risk of variceal bleed and are used for primary prophylaxis of variceal bleed.

Box 6.18: Drugs used in the treatment of portal hypertension.

Drugs that decrease portal blood flow:

- Nonselective β-adrenergic blocking agents (propranolol, nadolol, carvedilol)
- Somatostatin and its analogs
- Vasopressin
- Drugs that decrease intrahepatic resistance
- α1-adrenergic blocking agents (e.g., prazosin)
- Angiotensin receptor blocking agents
- Nitrates

Esophageal Varices

Q. Discuss the diagnosis and management of esophageal variceal bleeding.

- About 90% of patients with cirrhosis will develop gastroesophageal varices, but only one-third of these will bleed from them.
- The most common site of bleeding is esophageal varices within 3–5 cm of the esophagogastric junction.
- Factors that predispose to rupture of varices are listed in **Box 6.19**.

Box 6.19: Factors predisposing varices rupture.

- Large varices
- "Red sign" on varices (diagnosed at endoscopy) suggests imminent rupture.
- Associated with severe liver disease
- High portal venous pressure
- Salicylates and other nonsteroidal anti-inflammatory drugs

Clinical Features

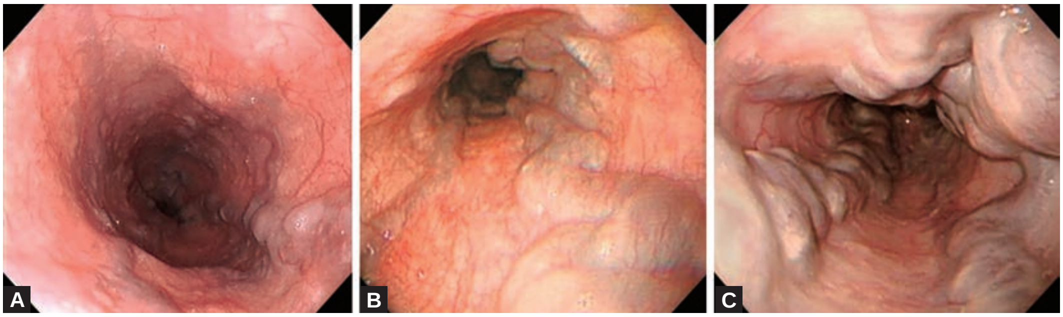
Painless, mild-to-massive hematemesis, with or without associated melena.

Signs

- **Depending on the amount of blood loss**, it may vary from mild postural tachycardia to shock.
- **Features of liver cell failure, ascites, and portal hypertension.**

Diagnosis

- **Fiberoptic endoscopy:** Performed within 8 hours of bleeding reveals the bleeding site and the presence of varices **(Fig. 6.20A to C)**. This helps in excluding the other causes of bleeding. The descriptors are presented in **Box 6.20**.
- **Ultrasonography:** Useful to confirm the patency of portal vein.



FIGS. 6.20A TO C: Endoscopy view of esophageal varices (Grade I, II, and III).

Gastric Varices

Gastric varices (GV) occur in ~20% of patients with cirrhosis.
GV are commonly classified per Sarin's classifications:

- GOV type 1 (GOV1) are EV extending below the cardia and into the lesser curvature (75% of GV)
- GOV type 2 (GOV2) are those extending into the fundus: isolated GV type 1 (IGV1) are located in the fundus; and isolated GV type 2 (IGV2) are located elsewhere in the stomach current recommendations for the treatment of actively bleeding are for either EVL or cyanoacrylate glue injection. TIPS/BRTO is very effective in the treatment of bleeding GV.

Q. Describe the management of acute variceal bleeding. Describe the medical management of bleeding of esophageal varices.

Box 6.20: Descriptors of esophageal varices.

- Red color signs (ominous signs) include:
  - Red "wale" markings, which are longitudinal whip-like marks on the varix
  - Cherry-red spots, which usually are 2–3 mm or less in diameter
  - Hematocystic spots are blood-filled blisters 4 mm in diameter
- Color of the varix can be white or blue
- Form (size) of the varix at endoscopy:
  - Grade I: Esophageal varices may be small and straight
  - Grade II: Tortuous and occupying less than one-third of the esophageal lumen
  - Grade III: Large and occupying more than one-third of the esophageal lumen

Management

Management goal **(Box 6.21)**.

Management of acute variceal bleeding (Flowchart 6.3)

General measures—resuscitation

- **Immediate hospitalization and nursing:** Patients require intensive-care nursing. Nil by mouth until bleeding stops.

Box 6.21: Management goal in esophageal varices.

- Management of the active bleeding episode
- Prevention of rebleeding
- Prophylactic measures to prevent the first hemorrhage

- Assess the general condition of the patient pulse and blood pressure and maintain fluid (intake and output) and electrolyte balance.
- Obtain blood for grouping and crossmatching, hemoglobin, prothrombin time, blood urea, electrolytes, creatinine, LFTs, and blood cultures.
- Grade cirrhosis according to Child-Pugh score (*refer* **Table 6.33**).
- Immediately restore blood volume with blood transfusion and avoid saline infusions as far as possible. Prompt correction of hypovolemia is needed.
- Correction of coagulation factor deficiency by fresh blood or fresh frozen plasma.
- Platelet transfusions to raise platelet count above 50,000/mm^3.
- Vitamin K is administered intramuscularly or intravenously.
- To prevent stress ulcers, give H_2 receptor antagonists (e.g., cimetidine, ranitidine or famotidine) or proton-pump inhibitors (e.g., pantoprazole or omeprazole).
- **Prophylactic antibiotics:** Reduce infection and mortality and prevent spontaneous bacterial peritonitis (SBP). Usually oral and intravenous quinolones are used (e.g., ciprofloxacin 500 mg twice daily).
- **Measures to prevent hepatic encephalopathy:** Portosystemic encephalopathy (PSE) may be precipitated when the amount of bleeding is large because blood contains protein.
- Treatment of ascites by ascitic tap (paracentesis) or by administration of spironolactone or amiloride.
- Monitor for alcohol withdrawal (in case of alcoholic cirrhosis) and give thiamine.

A. Hemostatic clips
B. Band ligation

Urgent endoscopy

- Urgent endoscopy is done to confirm the diagnosis of gastroesophageal varices. Varices may or may not be present and it helps to exclude bleeding from other sites (e.g., gastric ulceration).
- **Portal hypertensive (or congestive) gastropathy** is defined as chronic gastric congestion, punctate erythema, and gastric erosions. It can also cause bleeding.
- To reduce esophageal ulceration following endoscopic therapy, sucralfate is given in the dose of 1 g four times daily.

Local measures

Injection sclerotherapy or variceal banding

Acute variceal bleeding may be treated by endoscopic procedure with (1) sclerotherapy and (2) endoscopic variceal banding [endoscopic variceal band ligation (EVBL)]. They arrest bleeding in 80% of cases and reduce early rebleeding.

- **Sclerotherapy:** Injection of sclerosing agent into the varices may arrest bleeding by producing thrombosis of vessel. Commonly used sclerosants are listed in **Box 6.22** and complications of sclerotherapy are mentioned in **Table 6.37**.
- **Banding (Fig. 6.21):** Varices are banded by mounting a band on the tip of the endoscope, sucking the varix just into the end of the scope and dislodging the band over the varix.
- **Cyanoacrylate injection** is used in patients with large gastric varices.

Box 6.22: Commonly used sclerosants in esophageal varices.

- Ethanolamine oleate
- Sodium morrhuate
- Absolute alcohol
- Sodium tetradecylsulfonate

TABLE 6.37: Complications of sclerotherapy.

Esophageal complications: ➢ Reappearance of varices ➢ Esophageal ulceration and perforation ➢ Esophageal reflux ➢ Stricture formation	Pulmonary complications: ➢ Chest pain, pleural effusion, mediastinitis, and aspiration pneumonia ➢ Acute respiratory failure
Abdominal pain, fever, and dysphagia	➢ Spinal cord paralysis due to anterior spinal artery occlusion ➢ Mortality: 1%

Vasoconstrictor therapy

Uses: This therapy is mainly used for (1) emergency control of bleeding while waiting for endoscopy, and (2) in combination with endoscopic techniques.

Aim: To reduce the portal inflow of blood and portal pressure constricting the splanchnic arterioles.

Drugs used

- **Terlipressin**
  - Action: Terlipressin produces vasoconstriction by releasing vasopressin from it.
  - Dose: 2 mg IV 6-hourly till bleeding stops, and then reduced to 1 mg 4-hourly after 48 hours if a prolonged dosage regimen is used.
  - Contraindication: Patients with ischemic heart disease.
  - Side effects: Abdominal colic, evacuation of bowels, and facial pallor due to the generalized vasoconstriction.
- **Somatostatin and octreotide**
  - Somatostatin and its synthetic analog octreotide stops bleeding from varices in more than 80% patients.
  - Its effects are equivalent to vasopressin and endoscopic therapy.
  - Side-effects: Very few.
  - Dose:
    - Somatostatin: Infusion of 250–500 µg/h followed by 250 µg/h for 2–5 days.
    - Octreotide: 50 µg as bolus followed by 50 µg/h for 2–5 days.
  - Indication: When there are contraindications to terlipressin.
- Vasopressin [0.1–0.5 units/min for 4–12 hours (up to 48 hours)]: It was used in the past but is not commonly used now.

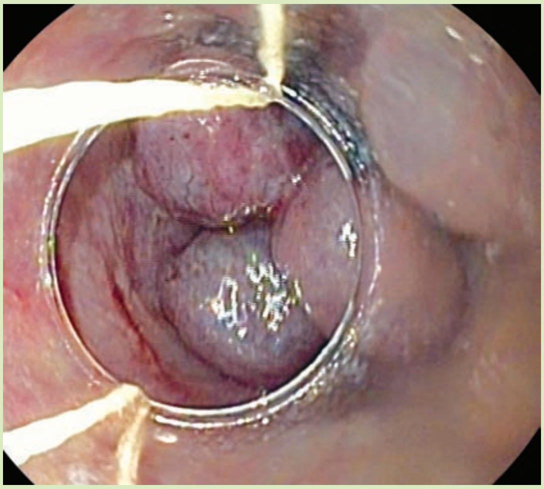

FIG. 6.21: Banding of esophageal varices.

Balloon Tamponade

- Indications: To control variceal bleeding
  - If endoscopic therapy or vasoconstrictor therapy fails or contraindicated
  - If there is exsanguinating hemorrhage
- Instrument: (1) Sengstaken–Blakemore tube with four lumens, and (2) Minnesota tube with four lumens. These tubes have two balloons, namely esophageal and gastric balloons.
- Use: It is very useful in the initial few hours of bleeding in about 90% of cases.
- Complications: (1) Aspiration pneumonia, (2) esophageal rupture, and (3) necrosis and ulcerations of esophageal mucosa, and (4) obstruction to pharynx.
- Algorithm for the treatment of bleeding from acute esophageal varices **(Flowchart 6.3)**

Management of an Acute Rebleed

- About 30% of patients develop rebleed within 5 days after a single therapeutic endoscopy.
- Source of the rebleed should be established by endoscopy. Sometimes it is due to an ulcer developed due to previous sclerotherapy and it is difficult to manage.
- Management: Repeat endoscopic therapy once only to control rebleeding and further sclerotherapy or banding should not be done.

Transjugular Intrahepatic Portocaval Shunt (TIPS)

- Indication: When the bleeding does not stop after two sessions of endoscopic therapy within 5 days.
- Technique: A guidewire is passed from the jugular vein into the liver. An expandable metal shunt is forced over it into the liver substance (intrahepatic) to form a portocaval shunt (between the systemic and portal venous systems).
- Advantages: It reduces the hepatic sinusoidal and portal vein pressure without the risks of general anesthesia and major surgery.
- Disadvantages: It is useful only for the short-term.
- If the patient does not respond, transjugular intrahepatic portosystemic shunt (TIPSS) is useful in most patients.

Emergency Surgery

- Indications: (1) When other measures fail, (2) if TIPS is not available, (3) continued or recurrent hemorrhage, and (4) if the bleeding is from gastric fundal varices.
- Techniques: Esophageal transection and ligation of the feeding vessels to the bleeding varices. Infrequently acute portosystemic shunt surgery and esophageal staple transaction.

PREVENTION OF VARICEAL BLEEDING—PROPHYLAXIS

Primary Prophylactic Measures	
Useful in patients with cirrhosis and varices, who have not bled.	
Nonselective β-blockers: Propranolol, nadolol ➢ Reduce chance of upper GI bleeding, cost-effective. Reduce recurrence. ➢ Efficacy is similar to prophylactic banding. ➢ Act by vasodilatation of splanchnic arterial bed and portal venous system.	**Nitrates:** Nitroglycerine, isosorbide dinitrate Given with-blockers—reduced risk of variceal bleed Variceal banding is done if there are contraindications or intolerance to nonselective beta-blockers
Recurrent Variceal Bleeding (Secondary Prophylaxis)	
Bleeding recurs in about 60–80% of patients within 2 years after initial bleed.	
Long-term measures	**Surgical portosystemic shunting**
Nonselective beta-blockers: Treatment of choice. Propranolol: 80–160 mg/day oral, decreases portal pressure, decreases frequency of rebleed (as effective as sclerotherapy or ligation), prevents bleeding from portal hypertensive gastropathy. **Endoscopic treatment:** Injection sclerotherapy or variceal banding. Repeated courses of banding done every 2 weeks until the varices are obliterated. It is superior to sclerotherapy. **Transjugular portosystemic stent shunts:** Reduce rebleeding rates compared to endoscopic techniques but associated with increased rate of encephalopathy. Used if endoscopic or medical therapy fails.	Performed in patients with good liver function (Child–Pugh A, B), when medical therapy, EVBL and sclerotherapy are unsuccessful with very low risk of rebleeding. **Types of portal systemic shunts:** ➢ *Nonselective shunt with end-to-side portocaval anastomosis* decompresses entire portal venous system, produces significant postoperative hepatic encephalopathy. ➢ *Selective distal splenorenal (Warren) shunt*—decompress only varices while maintaining blood flow to liver via superior mesenteric vein, produces less encephalopathy. **Complications of portosystemic shunts** 5% mortality, shunt closure, hepatic encephalopathy due to reduction in portal pressure and hepatic blood flow, postoperative jaundice because of deterioration of liver function. **Esophageal transection:** Devascularization procedure that does not produce encephalopathy. **Liver transplantation:** Treatment of choice when liver function is poor.

HEPATIC ENCEPHALOPATHY

Q. IM5.6, 5.16 **Describe and discuss the pathophysiology, clinical evolution and complications and management of hepatic encephalopathy.**

Definition

Hepatic encephalopathy or portosystemic encephalopathy is defined as a **neuropsychiatric syndrome** (alteration in mental status and cognitive function) occurring **secondary to chronic liver disease**. Encephalopathy may be **acute** and potentially reversible, **or chronic** and progressive.

Etiology

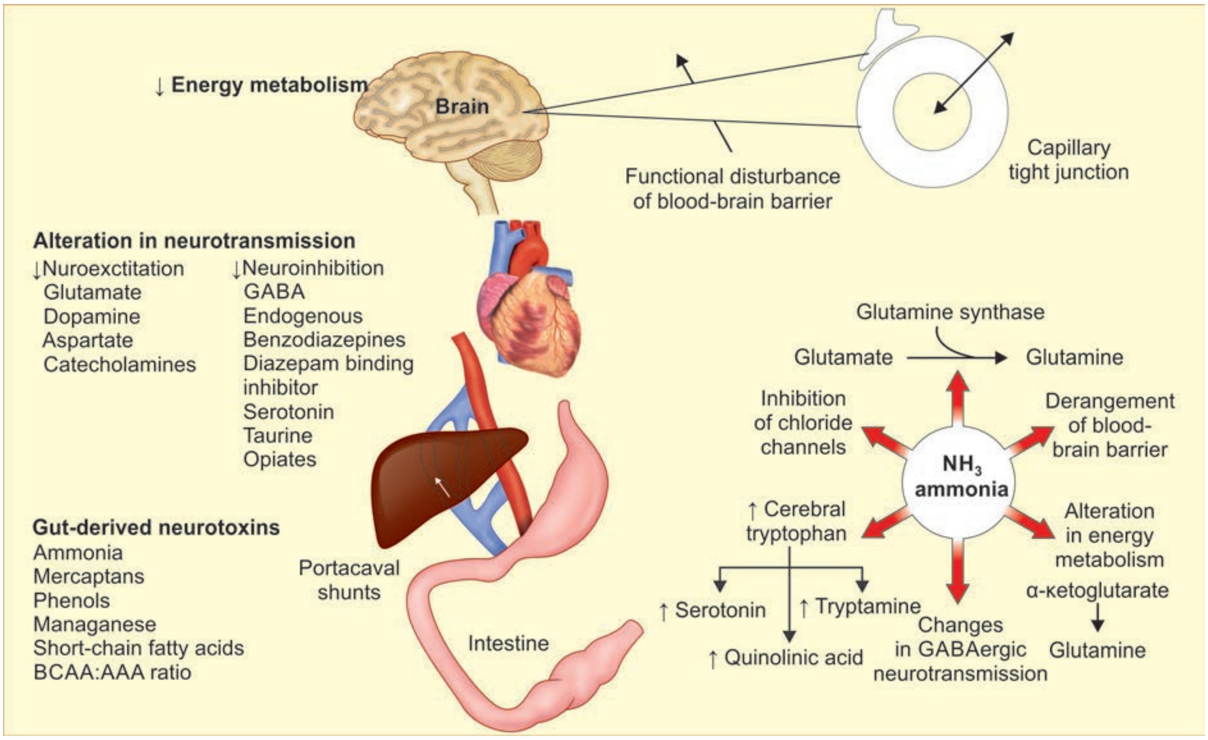
- More common in patients with chronic liver disease such as **cirrhosis**. In patients with portal hypertension, it develops due to spontaneous "shunting" or in patients following a **portosystemic shunt procedure**, e.g., TIPS (transjugular intrahepatic portocaval shunt). *Adult-onset citrullinemia type II closely mimics hepatic encephalopathy*.
- Acute encephalopathy can occur in **acute fulminant hepatic failure**.

Pathogenesis

Mechanism is unknown but many factors play a role. Six pathogenic mechanisms have been proposed.

1. Gut-derived neurotoxins that are normally metabolized by the liver
2. Brain water homeostasis
3. Oxidative/nitrosative stress
4. Astrocyte dysregulation
5. Neurotransmitter dysfunction (decreased glutamine, increased GABA, serotonin)
6. Infection and inflammation

Hepatic encephalopathy develops **due to disturbance of brain function resulting from various toxic substances reaching the brain**. Normally, these toxic substances are derived from the intestine (gut-derived neurotoxins) and carried by portal circulation to the liver, where they are detoxified. Hence, they neither enter the systemic circulation nor reach the brain.



↓ Energy metabolism
Brain
Functional disturbance of blood-brain barrier
Capillary tight junction

↑ Cerebral tryptophan
Alteration in energy metabolism
α-ketoglutarate
↑ Serotonin
↑ Tryptamine
↑ Quinolinic acid
Changes in GABAergic neurotransmission
Glutamine

(BCAA:AAA: Branched-chain amino acid:aromatic amino acid; GABA: Gamma aminobutyric acid)

In hepatic encephalopathy, these toxic substances are not removed by the liver and reach the brain. **Three factors are responsible** for this are:

1. **Vascular shunting/bypassing the liver:** The portal blood bypasses the liver via the collaterals into systemic circulation and the "toxic" metabolites pass directly to the brain.
2. **Decreased liver mass:** It results in severe hepatocellular dysfunction leading to defective detoxification of the toxic substances.
3. **Increased permeability of the blood-brain barrier:** Allows the toxins to enter the brain.

Toxic substances: Involved in hepatic encephalopathy is listed in **Table 6.38. Ammonia plays a major role** and is produced by the breakdown of protein by intestinal bacteria.

TABLE 6.38: Toxic substances involved in hepatic encephalopathy.

Ammonia plays major role	Aromatic amino acids (tyrosine and phenylalanine)
Free fatty acids	Reduced branched-chain amino acids (valine, leucine and isoleucine)
Mercaptans derived from methionine	Phenol, Indole (oxindole)
γ-aminobutyric acid (GABA)	False neurotransmitters (octopamine)

Precipitating Factors for Portosystemic/Hepatic Encephalopathy (Table 6.39)

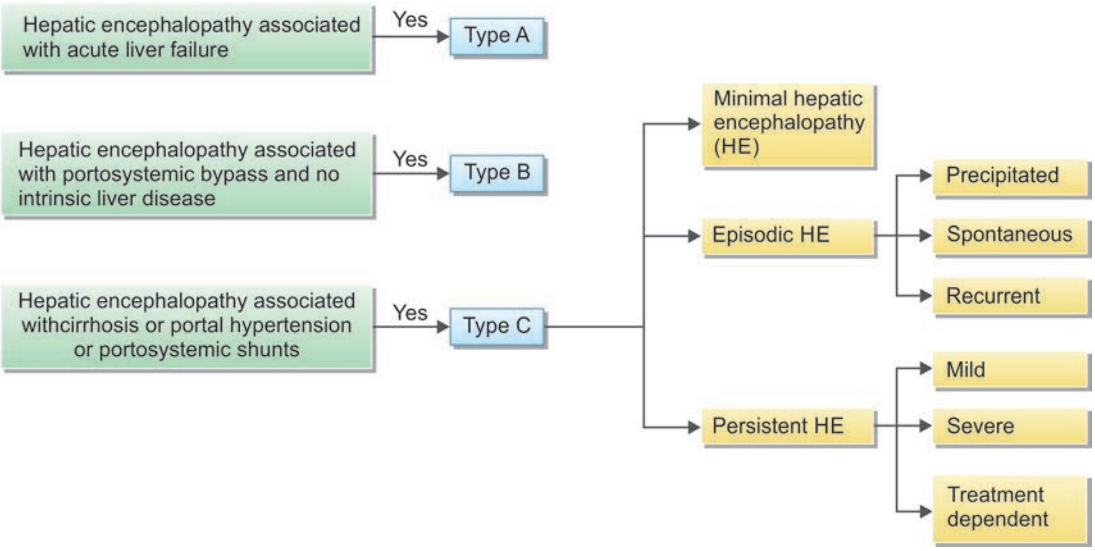
Q. List the precipitating causes of hepatic encephalopathy.

TABLE 6.39: Precipitating factors for hepatic/portosystemic encephalopathy.

➢ Increased protein load	Acute infections including spontaneous bacterial peritonitis
– Dietary protein	Drugs, e.g., sedatives, antidepressants, narcotics, alcohol
– Gastrointestinal bleeding	Viral/alcoholic hepatitis
➢ Fluid and electrolyte disturbance such as hypokalemia, hyponatremia, metabolic alkalosis due to:	Surgical procedure: Portosystemic shunt operations
– Large-volume paracentesis	Development of hepatocellular carcinoma, hepatic or portal vein thrombosis
– Overzealous use of diuretics	Uremia
– Vomiting and diarrhea	Constipation

Types of Hepatic Encephalopathy (Flowchart 6.4)

FLOWCHART 6.4: Types of hepatic encephalopathy.



Hepatic encephalopathy associated with acute liver failure
Yes
Type A
Hepatic encephalopathy associated with portosystemic bypass and no intrinsic liver disease
Yes
Type B
Hepatic encephalopathy associated withcirrhosis or portal hypertension or portosystemic shunts
Yes
Type C
Minimal hepatic encephalopathy (HE)
Episodic HE
Precipitated
Spontaneous
Recurrent
Persistent HE
Mild
Severe
Treatment dependent

Note: Recent discussions have also proposed the **fourth type (type D)** to separately include HE patients with acute-on-chronic liver failure (ACLF), because they are different in terms of their clinical, pathophysiological, and prognostic features from those with types A–C.

Clinical Features

- **Acute hepatic (portosystemic) encephalopathy** often has a precipitating factor (**Table 6.35**) and the patient becomes drowsy and comatose within weeks to months. Brain edema may occur with severe encephalopathy and may lead to cerebral herniation.
- **Chronic hepatic (portosystemic) encephalopathy**
- **Disturbances in consciousness and behavior** may fluctuate. Hypersomnia is the earliest feature and may progress to **reversion of sleep rhythm (daytime somnolence).** Patient may become quite violent and difficult to manage or may be very sleepy and difficult to rouse. Patients are **irritable, confused, disoriented** with slow slurred speech, later may become drowsy and eventually progress to coma.
- **Change in personality mood and intellect**
- **General features:** Nausea, vomiting, and weakness.

Grading of HE according to the West Haven criteria (WHC) and the competing ISHEN criteria, which contrast covert and overt hepatic encephalopathy are presented in **Table 6.40**.

TABLE 6.40: Grading of HE according to the West Haven criteria (WHC) and the competing ISHEN criteria.

WHC including MHE	*ISHEN*	*Description*	*Suggested operative criteria*	*Comment*
Unimpaired		No encephalopathy at all, no history of HE	Tested and proved to be normal	
Minimal	**Convert**	Psychometric or neuropsychological alterations of tests exploring psychomotor speed/executive functions or neurophysiological alterations without clinical evidence of mental change	Abnormal results of established psychometric or neuropsychological tests without clinical manifestations	No universal criteria for diagnosis. Local standards and expertise required
Grade I		➢ Trivial lack of awareness ➢ Euphoria or anxiety ➢ Shortened attention span ➢ Impairment of addition or subtraction	Despite oriented in time and space (See below), the patient appears to have some cognitive/ behavioral decay with respect to his/her standard on clinical examination, or to the clinical examination, or to the caregivers	Clinical findings usually not reproducible
Grade II	**Overt**	➢ Lethargy or apathy ➢ Disorientation for time ➢ Obvious personality change ➢ Inappropriate behavior	Disoriented for time (at least three of the followings are wrong; day of the month, day of the week, month, season, year) +/– the other mentioned symptoms	Clinical findings variable but reproducible to some extent

Contd...

Contd...

WHC including MHE	*ISHEN*	*Description*	*Suggested operative criteria*	*Comment*
Grade III		➢ Somnolence to semi-stupor ➢ Responsive to stimuli ➢ Confused ➢ Gross disorientation ➢ Bizarre behavior	Disoriented also for space (at least three of the following wrongly reported country, state or region, city, place, +/– the other mentioned symptoms)	Clinical findings reproducible to some extent
Grade IV		Coma	Do not respond even to pain stimuli	Comatose state usually reproducible

(HE: Hepatic encephalopathy; ISHEN: International Society for Hepatic Encephalopathy and Nitrogen Metabolism; MHE: Minimal hepatic encephalopathy; WHC: West Haven criteria)

Signs

- **Fetor hepaticus** (a sweet smell to the breath).
- **Asterixis** (flapping tremors) (*refer* **Fig. 6.15A**) is a motor disturbance marked by intermittent lapses of an assumed posture, as a result of intermittency of sustained contraction of groups of muscles. Usually manifests as a bilateral flapping tremor at the wrist, metacarpophalangeal, and hip joints. It may also be seen in tongue, foot, and any skeletal muscle.
    - **Mechanism:** Probably due to interruption of the posture pathway in the rostral reticular formation and abnormal joint proprioception.
    - The lapse of posture has been termed **"negative myoclonus"** because during tonic muscle contraction (i.e., posture), a short electromyography (EMG) silent period precedes the tremor.
    - **Causes:** Hepatic encephalopathy, renal failure, metabolic encephalopathy, CO_2 toxicity, Wilson's disease, electrolyte abnormalities (hypoglycemia, hypokalemia, and hypomagnesemia), drug intoxications [e.g., barbiturate intoxication, alcoholism, phenytoin intoxication ("phenytoin flap") and primidone intoxication] and psychotropic drugs (clozapine, sodium valproate, and risperidone). Lesions in the genu and anterior portion of the internal capsule or ventrolateral thalamus may cause unilateral asterixis.
- Fluctuating neurological signs
- Constructional apraxia with the patient being unable to write or draw
- Hypertonia—later hypotonia
- Hyperreflexia and extensor plantar, later loss of reflexes

International Society for Hepatic Encephalopathy and Nitrogen Metabolism (ISHEN) criteria and Full Outline of Unresponsiveness (FOUR) which assesses four components—eye response, motor response, brain-stem reflex, and respirations are better scoring systems.

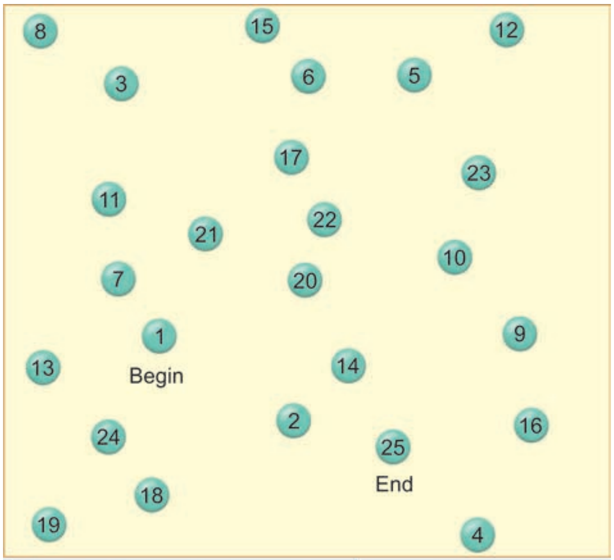
Diagnosis: It is based on clinical features. Diagnosis of minimal hepatic encephalopathy is currently based on neuropsychometric tests, including the number connection test, digit symbol test, and the block design test.

Reitan Number Connection Test (Fig. 6.22)

There are 25 numbered circles which can normally be joined together within 30 seconds.

Critical Flicker Frequency

- Critical Flicker frequency (CFF) is a test of retinal gliopathy (that occurs in patients with HE) that can be performed using a portable machine.
- During this test, the patient is asked to indicate the maximum frequency at which they can still perceive the light as flickering while changing the frequency over time.



Time required in seconds	HE grade
≤30	None-minimal
31–50	Minimal-I
51–80	I-II
81–120	II-III
Forced termination	III

FIG. 6.22: Number connection test.

- A CFF threshold of 38–39 Hz has been shown to differentiate between manifest HE (i.e., early stages of OHE) and no HE.

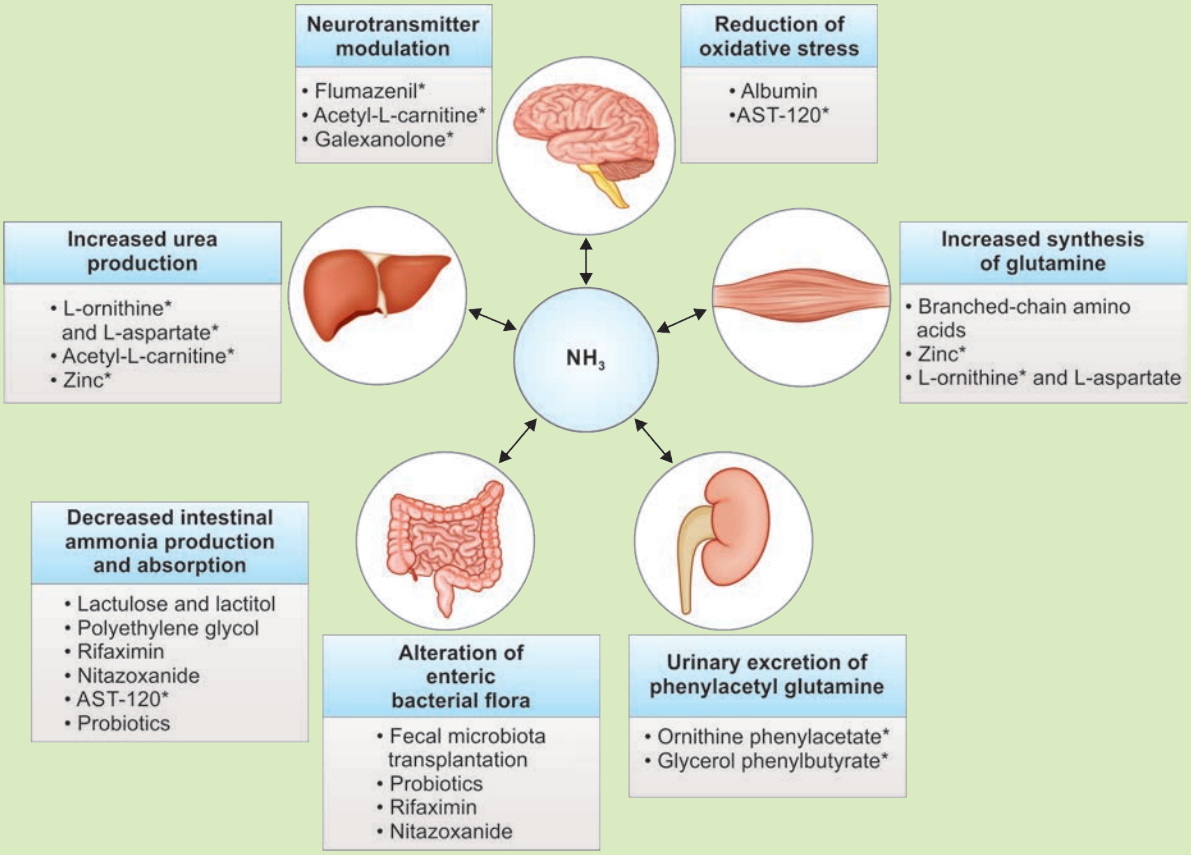
Investigations

- **Blood ammonia levels: Raised** (upper limit of normal is 0.8–1 µg/mL) and can be used for the differential diagnosis of coma and to follow a patient with PSE.
- Serum levels of **3-nitrotyrosine** may be elevated in patients with minimal hepatic encephalopathy.
- **Electroencephalography (EEG):** Bilaterally synchronous decrease in wave frequency and an increase in wave amplitude, associated with the disappearance of a readily discernible normal alpha-rhythm (8–13 cps).
- **Cerebrospinal fluid: Glutamine increased,** proteins normal, and cell count normal.
- Visual evoked potential abnormalities may be present during subclinical encephalopathy.
- Routine LFTs only confirm the presence of liver disease and not the presence of encephalopathy.
- Imaging is performed to rule out other causes.

Q. Write short note on treatment of hepatic encephalopathy.

Treatment of hepatic encephalopathy (Fig. 6.23)

Treatment is multifactorial. Restriction of protein intake is reserved for resistant cases.



Neurotransmitter modulation
• Flumazenil*
• Acetyl-L-carnitine*
• Galexanolone*
Reduction of oxidative stress
• Albumin
•AST-120*
Increased urea production
• L-ornithine* and L-aspartate*
• Acetyl-L-carnitine*
• Zinc*
NH$_3$
Increased synthesis of glutamine
• Branched-chain amino acids
• Zinc*
• L-ornithine* and L-aspartate
Decreased intestinal ammonia production and absorption
• Lactulose and lactitol
• Polyethylene glycol
• Rifaximin
• Nitazoxanide
• AST-120*
• Probiotics
Alteration of enteric bacterial flora
• Fecal microbiota transplantation
• Probiotics
• Rifaximin
• Nitazoxanide
Urinary excretion of phenylacetyl glutamine
• Ornithine phenylacetate*
• Glycerol phenylbutyrate*

FIG. 6.23: Established and novel treatment modalities used in hepatic encephalopathy treatment.

*There are no ongoing clinical trials to further investigate the role of this agent in hepatic encephalopathy management according to Clinical Trials.

General measures:

- Management or removal of the precipitating factors is the most important aspect in the treatment.
- Maintain nutrition with adequate calories 35–40 kcal/kg/day.

- Maintain hydration and correct the electrolyte imbalance.
- **Protein restriction** in the diet. Administer 1.0–1.2 g/kg of proteins daily, preferably vegetable protein.
- Zinc supplementation may be helpful and is relatively harmless.
- Stop or reduce diuretic therapy.
- Treat any infection with **suitable antibiotics** (e.g., ampicillin, rifaximin, metronidazole, or neomycin).
- Stop alcohol. **Avoid sedatives.** For restlessness and excitement, small dose of diazepam or midazolam may be given intravenously.

Evacuation of the bowels and sterilizing the bowel:

- Give purgation and enemas to empty the bowels of nitrogenous substances.
- **Lactulose therapy:** To reduce plasma ammonia level
    - **Actions:** Lactulose (beta-galactosidofructose) is a nonabsorbable disaccharide, which acts as an osmotic purgative. In the colon, lactulose and lactitol are catabolized by the bacterial flora to lactic acid and acetic acid. It lowers the colonic pH and favors the formation of the nonabsorbable NH^+ from NH, trapping NH^+ in the colon and thus reducing plasma ammonia concentrations. Other mechanisms of action include (1) increased incorporation of ammonia by bacteria for synthesis of nitrogenous compounds, (2) modification of colonic flora, resulting in displacement of urease-producing bacteria with nonurease-producing bacteria and cathartic effects that improves GI transit, allowing less time for ammonia absorption, (3) increased fecal nitrogen excretion due to the increase in stool volume, and (4) reduced formation of toxic short-chain fatty acids (e.g., propionate, butyrate, valerate).
    - **Dose:** 15–30 mL three times orally per day. Dose is increased gradually till there are two to three loose stools per day.
    - **Lactitol** (β-galactoside sorbitol 30 g daily): It has a similar action, more palatable and better than lactulose.
        - Poorly absorbed antibiotics: They are often used as adjunctive to sterilize the gut in patients who have difficulty with lactulose. They reduce the intestinal ammonia production by bacteria.
        - Alternating administration of **neomycin and metronidazole** to reduce the individual side effects of each neomycin for nephrotoxicity and ototoxicity and metronidazole for peripheral neuropathy.
        - **Rifaximin** semisynthetic, gut-selective, and nonabsorbable oral antibiotic, derived from rifamycin and a structural analog of rifampin in the dose of 550 mg twice daily or 400 mg thrice daily is very effective and without any side effects of neomycin or metronidazole. It has only 0.4% systemic absorption.
    - When there is GI bleeding, Ryle's tube aspiration and bowel washes are performed to remove the blood and blood products. It reduces the production of nitrogen in the gut.
    - *Other drugs tried are:*
        - Bromocriptine
        - L-ornithine L-aspartate (LOLA): They are endogenous amino acids that act as substrates for the urea cycle and help with ammonia detoxification. LOLA can also increase urea production by activating the rate limiting enzyme of urea cycle, carbamoyl phosphate synthetase. By activation of glutamine synthetase, LOLA also augments glutamine production in perivenous hepatocytes and skeletal muscles.
        - Acetyl-L-carnitine: It plays a role in transferring fatty acid across the inner mitochondrial membrane, and ester of this nutrient, acetyl-L-carnitine, has been hypothesized to induce ureagenesis leading to decreased ammonia levels in blood and brain and HE improvement. It also increases acetylcholine production in the brain and enhances synthesis of proteins and phospholipids that alleviate neuronal toxicity in HE.
        - Branched-chain amino acids: The 3 essential branched-chain amino acids (BCAAs) are valine, leucine, and isoleucine.
        - Nitazoxanide (NTZ): It is an antimicrobial agent with wide safety profile that has broad-spectrum activity against urease-producing bacteria leading to decreased ammonia production.
        - Probiotics and prebiotics
        - Acarbose
        - Sodium benzoate
        - Ornithine phenylacetate
        - Golexanolone
        - Glycerol phenylbutyrate
        - Zinc
        - Polyethylene glycol
        - Flumazenil
        - Melatonin
        - Fecal microbiota transplantation

- Novel treatment strategies include use of L-carnitine, rivastigmine, endocannabinoids, and mGluR1 antagonists.
  - In acute liver failure, mannitol and judicious use of intravenous fluids to reduce the spontaneous cerebral edema (controversial).
  - Liver transplantation.
  - **Albumin and albumin dialysis. MARS—**Molecular Adsorption Reversibility System—purifies the blood by removal of albumin bound as well as water-soluble substrates.

Management of hepatic encephalopathy is summarized in **Flowchart 6.5**.

Hepatorenal Syndrome

Q. Write a short note on hepatorenal syndrome.

- Hepatorenal syndrome (HRS) is a form of **functional azotemia without renal pathology in patients with advanced cirrhosis or acute liver failure**.
- The urine output is low, tubular function is normal, and kidneys are histologically normal.
- This occurs in 10% of patients with advanced cirrhosis with jaundice and ascites.

Pathogenesis

- **Initially, severe peripheral vasodilatation** (probably due to nitric oxide), leads to severe **reduction in the effective blood volume and hypotension**.
- This **activates** the homeostatic mechanisms and **rennin-angiotensin-aldosterone system leading to vasoconstriction of the renal vessels**.
- Increased preglomerular vascular resistance directs the flow of blood away from the renal cortex. This leads to a **reduced glomerular filtration rate**.
- **Eicosanoids** are another mediator involved in pathogenesis of HRS.

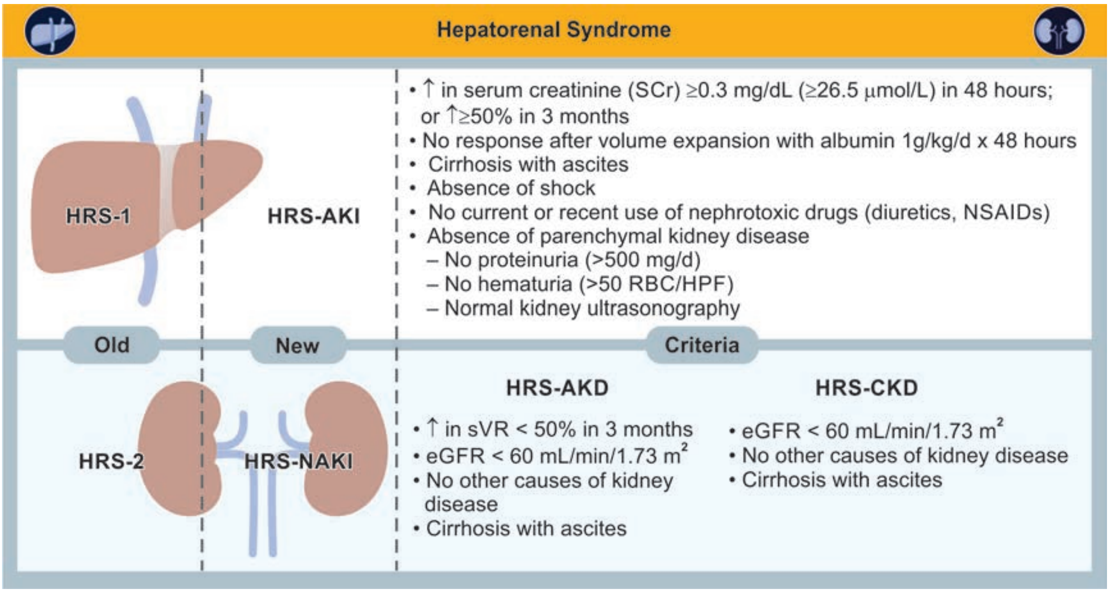
Precipitating Factors for HRS

See **Box 6.23**.

Box 6.23: Precipitating factors for hepatorenal syndrome (HRS).

- Gastrointestinal bleeding
- Aggressive paracentesis
- Diuretic therapy
- Sepsis including spontaneous bacterial peritonitis
- Diarrhea

Clinical Types



- ↑ in serum creatinine (SCr) ≥0.3 mg/dL (≥26.5 μmol/L) in 48 hours; or ↑≥50% in 3 months
- No response after volume expansion with albumin 1g/kg/d x 48 hours
- Cirrhosis with ascites
- Absence of shock
- No current or recent use of nephrotoxic drugs (diuretics, NSAIDs)
- Absence of parenchymal kidney disease
  - – No proteinuria (>500 mg/d)
  - – No hematuria (>50 RBC/HPF)
  - – Normal kidney ultrasonography

HRS-AKD

- ↑ in sVR < 50% in 3 months
- eGFR < 60 mL/min/1.73 m^2
- No other causes of kidney disease
- Cirrhosis with ascites

HRS-CKD

- eGFR < 60 mL/min/1.73 m^2
- No other causes of kidney disease
- Cirrhosis with ascites

(HRS: Hepatorenal syndrome; AKI: Acute kidney injury; NAKI: Non-acute kidney injury; eGFR: Estimated glomerular filtration rate; AKD: Acute kidney disease; CKD: Chronic kidney disease; RBC/HPF: Red blood cells per high power field; NSAIDs: Non-steroidal anti-inflammatory drugs)

Clinical Features

- Develops in advanced cirrhosis, almost always with ascites
- Anorexia, weakness, fatigue, oliguria, nausea, vomiting, and thirst
- Terminally coma deepens and hypotension develops.

Investigations

- **Urea and creatinine levels:** High
- **Serum sodium:** Less than 130 mEq/L
- **Urine sodium excretion:** Less than 10 mEq/day
- **Urinalysis:** Normal
- **Urine:** Plasma osmolality ratio is more than 1.5

Diagnosis

Usually made in the presence of a large amount of ascites in patients who have a stepwise progressive increase in creatinine. Diagnostic criteria HRS **(Box 6.24).**

Box 6.24: All of the following must be present for the diagnosis of hepatorenal syndrome (HRS).

- Cirrhosis with ascites
- Serum creatinine >1.5 mg/dL
- No improvement of serum creatinine (decrease to a level of 1.5 mg/dL or less) after at least 2 days of diuretic withdrawal and volume expansion with albumin
- Absence of shock
- No current or recent treatment with nephrotoxic drugs
- Absence of parenchymal kidney disease as indicated by proteinuria >500 mg/day, microhematuria (>50 red blood cells per high power field), and/or abnormal renal ultrasonography

Treatment

- **Prevention:**
  - Avoid over vigorous diuretic therapy
  - Slow treatment of ascites
  - Early recognition of electrolyte imbalance, hemorrhage, or infection
- **Stop diuretic therapy**
- **Correct hypovolemia** by intravenous plasma protein solution or salt-poor albumin
- Screen and **treat infection** including SBP
- An **albumin infusion** (1 g/kg bodyweight/day up to a maximum of 100 g/day) in combination with **terlipressin** (vasopressin analogs) is effective short-term medical therapy
- Currently, **midodrine** (α-agonist) along with octreotide and intravenous albumin is also used.
- Renal replacement therapy
- Transjugular intrahepatic portosystemic stent shunt (TIPSS) if vasoconstrictors fail

Liver transplantation is the treatment of choice.

ASCITES

Q. IM5.6, 5.16 Describe and discuss the pathophysiology, clinical evolution, complications and management of ascites.

Q. Discuss the definition, mechanism, causes, clinical features and differential diagnosis of ascites.

Ascites is defined as the **accumulation of excess fluid within the peritoneal cavity**.

The **most common** (85% of cases) **cause** of ascites is **portal hypertension** caused by **cirrhosis**; however, malignant or infectious causes can also produce ascites.

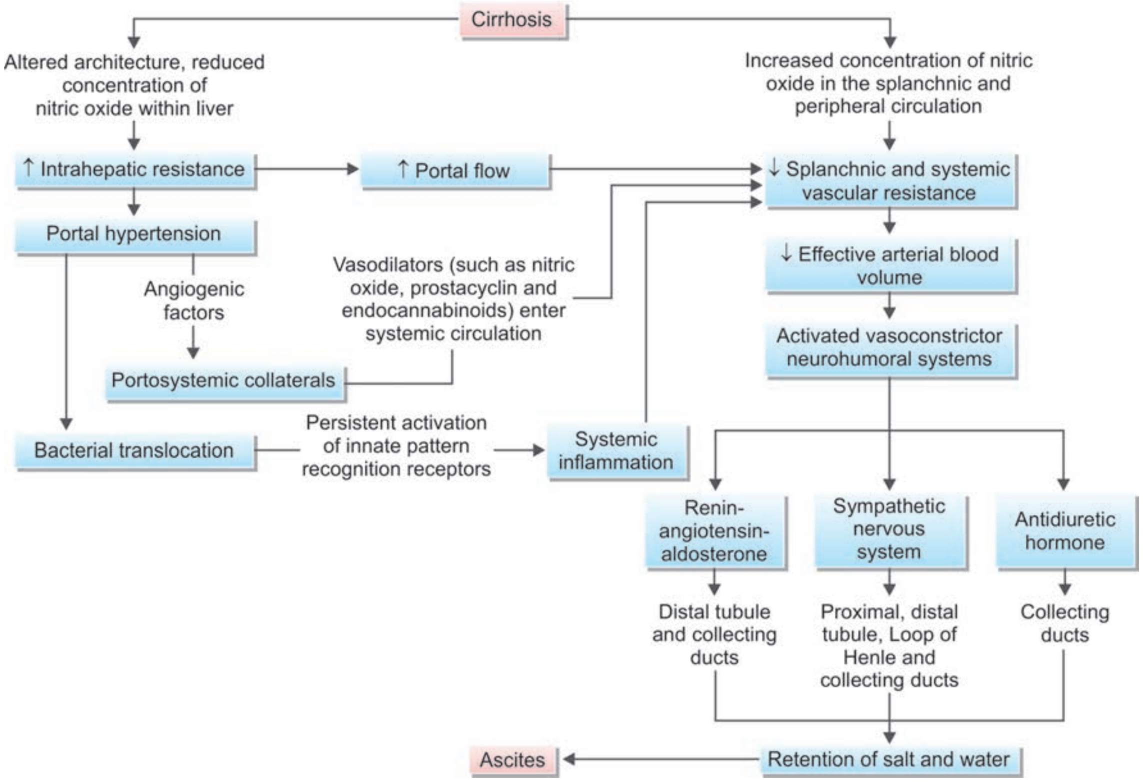
Pathogenesis/Mechanisms

Pathogenesis of Ascites in Cirrhosis (Fig. 6.24)

It is complex, involving the following mechanisms:

- **Portal hypertension:** Increase in portal vein hydrostatic pressure and results in extravasation of fluid from plasma into the peritoneal cavity.
- **Hypoalbuminemia:** Due to decreased synthetic function in a cirrhotic liver, plasma oncotic pressure is reduced. This results in an extravasation of fluid (ascites and edema).
- **Splanchnic vasodilation and hyperdynamic circulation**. It reduces systemic arterial blood pressure, activates **renin-angiotensin-aldosterone system** with the development of **secondary hyperaldosteronism.** Failure of liver to metabolize aldosterone intensifies secondary hyperaldosteronism. It leads to **sodium retention** and **fluid accumulation** and expansion of the extracellular fluid volume.

  The combination of portal hypertension, splanchnic arterial vasodilation, and sodium and water retention increases the hydrostatic pressure as well as permeability of interstitial capillaries. It causes extravasation of fluid into the peritoneal cavity.



Cirrhosis
Altered architecture, reduced concentration of nitric oxide within liver
Increased concentration of nitric oxide in the splanchnic and peripheral circulation
↑ Intrahepatic resistance
↑ Portal flow
↓ Splanchnic and systemic vascular resistance
Portal hypertension
Angiogenic factors
Vasodilators (such as nitric oxide, prostacyclin and endocannabinoids) enter systemic circulation
↓ Effective arterial blood volume
Activated vasoconstrictor neurohumoral systems
Portosystemic collaterals
Bacterial translocation
Persistent activation of innate pattern recognition receptors
Systemic inflammation
Renin-angiotensin-aldosterone
Sympathetic nervous system
Antidiuretic hormone
Distal tubule and collecting ducts
Proximal, distal tubule, Loop of Henle and collecting ducts
Collecting ducts
Ascites
Retention of salt and water

FIG. 6.24: Pathogenesis of ascites in cirrhosis.

- **Percolation of hepatic lymph into the peritoneal cavity:** In cirrhosis, hepatic lymphatic flow exceeds thoracic duct capacity. The excess lymph oozes freely from the surface of cirrhotic liver into the peritoneal cavity and causes ascites.

Theories of ascites:

- According to the **underfill theory**, transudation from the liver leads to reduction of the blood volume, thereby stimulating sodium (Na) retention by the kidney.
- According to the **overflow theory**, increased portal pressure stimulates renal Na retention through incompletely defined mechanisms.
- The **vasodilation theory** suggests that portal hypertension leads to vasodilation and relative arterial hypotension.

Pathogenesis

In Cirrhosis	*Absence of Cirrhosis*
Portal hypertension	**Inflammation of peritoneum**
Increase in portal vein hydrostatic pressure, cause extravasation of fluid from plasma into the peritoneal cavity.	Peritonitis from bacteria or mycobacteria causes increased vascular permeability and exudation of fluid into peritoneal cavity.
Hypoalbuminemia	**Venous obstruction**
Decreased synthetic function in cirrhosis reduces plasma oncotic pressure, results in extravasation of fluid (ascites and edema).	Inferior vena caval (IVC) obstruction increases the hydrostatic pressure, leads to transudation of fluid into peritoneal cavity.
Splanchnic vasodilation	**Lymphatic obstruction**
Reduction of arterial blood pressure activates **renin–angiotensin–aldosterone system** causing secondary hyperaldosteronism. Liver fails to metabolize aldosterone increased hyperaldosteronism. It causes **sodium and fluid retention.**	Obstruction of lymphatic flow due to involvement of mesenteric lymph nodes, thoracic duct, and abdominal lymphatic ducts can cause leakage of chyle into peritoneal cavity and can lead to chylous ascites.
Percolation of lymph	**Rupture of a viscus**
In cirrhosis, hepatic lymphatic flow exceeds thoracic duct capacity. Excess lymph oozes freely from the surface of cirrhotic liver into the peritoneal cavity causing ascites.	Outpouring of blood, cystic fluid, contaminated material, favoring ascites. Pancreatic ascites results from leakage of pancreatic enzymes into the peritoneum (pancreatitis).
Combination of portal hypertension, splanchnic arterial vasodilation, and sodium and water retention increases the hydrostatic pressure as well as permeability of interstitial capillaries. It causes extravasation of fluid into the peritoneal cavity.	**Malignancy** Primary peritoneal malignancies (mesothelioma, sarcoma), abdominal malignancies (gastric, colonic adenocarcinoma) or metastatic disease from breast, lung, or melanoma.

Clinical Features

Symptoms

- Distension of abdominal (increase in abdominal girth) and bloated feeling often accompanied by peripheral edema.
- Ascitic fluid may cause elevation of diaphragm and compromise respiratory function and produce dyspnea and orthopnea.
- Indigestion and heart burns due to gastroesophageal reflux may develop because of increased intra-abdominal pressure.
- Malnourishment and patients have muscle wasting and excessive fatigue and weakness.

Signs (Fig. 6.25 and Box 6.25)

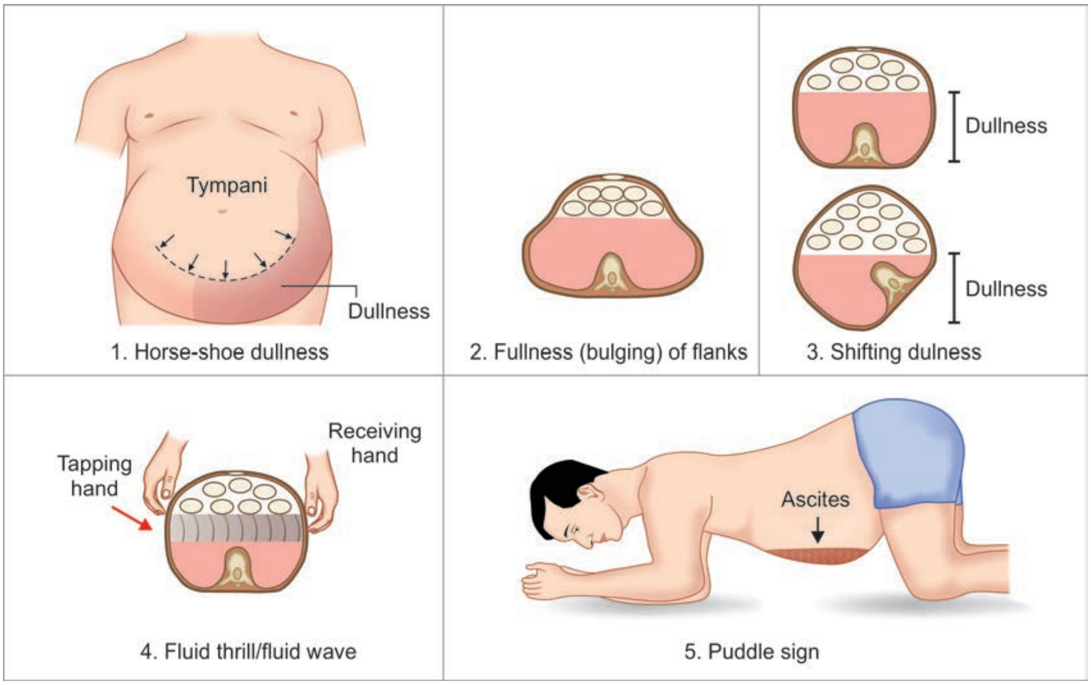
Box 6.25: Five signs of ascites.

1. Horseshoe dullness
2. Shifting dullness
3. Puddle sign
4. Fullness of flank
5. Fluid thrill/fluid wave

- Distension of abdomen and fullness of flanks (bloated feeling)
- Umbilicus appear flat or everted.
- Skin over the abdominal wall appear stretched and shiny.
- In the erect posture, hypogastrium appears prominent.
- Abdominal wall may show two types of distended veins:
    i. **Caput medusae** in which veins radiate out from the umbilicus with blood flow away from the umbilicus. They represent collaterals developed due to portal hypertension.
    ii. **Prominent veins in the flanks** with blood flow from below upward. They represent the IVC collaterals developed due to compression of IVC by severe ascites.
- **Abdominal dullness:** It indicates the presence of fluid in the abdominal cavity.
    - Dullness in the paraumbilical zone is detected with smaller amounts of fluid. This is elicited by asking the patient to assume knee elbow position and paraumbilical region percussed. Normally, the percussion note is tympanitic. With mild ascites the dullness is found only in the flanks.

Q. What is Puddle sign?

- **Puddle sign/Lawson's sign:** It can detect even ascites as low as 120 mL. Patient is asked to lie in prone position for 5 minutes, followed by knee elbow position. Place the diaphragm of the stethoscope on the most dependent part of the abdomen. Repeatedly flick one flank lightly. Diaphragm is gradually moved to the opposite flank. A marked change in the intensity and character of percussion note indicates the presence of fluid.
- With moderate ascites, both the flanks and hypogastric areas are dull **(horse shoe-shaped dullness)**. The epigastrium and umbilical regions show resonant note due to floating intestines.



1. Horse-shoe dullness
2. Fullness (bulging) of flanks
3. Shifting dulness
4. Fluid thrill/fluid wave
5. Puddle sign

FIG. 6.25: Signs of ascites.

- With massive ascites, the whole of the abdomen is dull, except for a small region over the umbilicus.
- For elicitation, **shifting dullness** at least of 500–1000 mL of fluid is required.
- **Fluid thrill** can be elicited in tense ascites (fluid more than 2,000 mL).

Secondary effects

- **Edema of scrotum**.
- **Pedal edema:** Due to hypoproteinemia and a functional block of IVC caused by tense ascites.
- **Pleural effusion:** Mainly on the right side. Pleural effusion is due to defects in the diaphragm that allows the ascitic fluid to pass into the pleural cavity.
- **Cardiac apex: Shifted upward** because of raised diaphragm
- **Distension of neck veins:** Secondary to a raised right atrial pressure, which follows tense ascites and raised diaphragm.
- **Meralgia paresthetica:** It can develop due to compression of lateral cutaneous nerve of thigh.
- Divarication of recti and hernia.

Definitions

Uncomplicated ascites

- Ascites that is not infected and which is not associated with the development of the hepatorenal syndrome (HRS).
- Ascites can be graded as mild when ascites is detectable only by ultrasound examination, moderate when it causes moderate symmetrical distension of the abdomen and large when it causes marked abdominal distension.

Refractory ascites

Ascites that cannot be mobilized or the early recurrence of which (i.e., after therapeutic paracentesis) cannot be satisfactorily prevented by medical treatment. This includes two different subgroups.

1. Diuretic-resistant ascites

Ascites that is refractory to dietary sodium restriction and intensive diuretic treatment.

2. Diuretic-intractable ascites

Ascites that is refractory to treatment owing to the development of diuretic-induced complications that preclude the use of an effective diuretic dosage.

Investigations

Ultrasonography: It is very sensitive and can detect even small amounts of ascitic fluid and also useful in identifying the cause.

- **Paracentesis and evaluation of ascitic fluid**.
- **Laparoscopy and biopsy of peritoneum.**

Aspirate about 10–20 mL of ascitic fluid and ascitic tap (**Fig. 6.26**) the following tests are performed:

- ***Cell count*:** A neutrophil count above 250 cells/mm^3 usually indicates SBP.
- ***Gram stain and culture*:** For bacteria and acid-fast bacilli.
- ***Protein*:** Total ascitic fluid protein less than 1.5 g/dL indicates an increased risk of SBP.
- ***SAAG (serum ascites albumin gradient):*** It is the differences between serum albumin and ascitic fluid albumin. SAAG is useful for differentiating ascites caused by portal hypertension from nonportal hypertensive ascites. It is calculated by subtracting the ascitic albumin concentration form the serum albumin concentration and does not change with diuresis. It is **better indicator** than simple estimation of protein in the ascitic fluid. SAAG is not a ratio, it is the difference. Classification of ascites based on SAAG is presented in **Table 6.38**. Corrected SAAG = Uncorrected SAAG × 0.16 × (Serum globulin g/dL + 2.5).
- ***Cytology*:** For malignant cells to exclude neoplasms causing ascites.
- ***Amylase*:** To exclude pancreatic ascites. It is increased in acute pancreatitis.

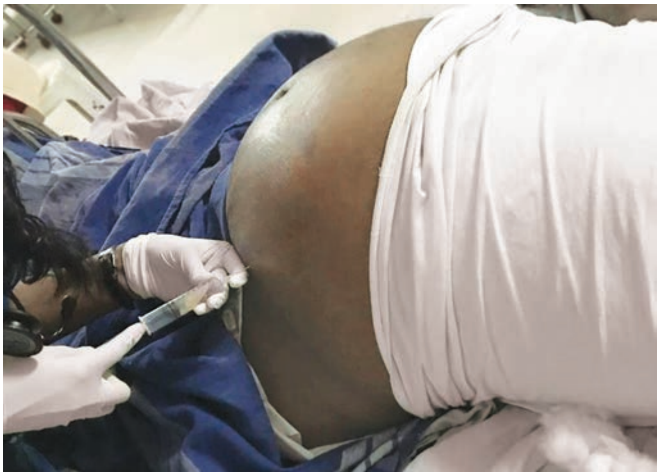


FIG. 6.26: Ascitic tap.

Ascitic fluid changes in cirrhosis are presented in **Table 6.41**. Causes of high- and low-serum-ascites albumin gradient (**Table 6.42**).

TABLE 6.41: Causes of high and low serum-ascites albumin gradient.

Causes of high serum-ascites albumin gradient (>1.1 g/dL)	*Causes of low serum-ascites albumin gradient (<1.1 g/dL)*
➢ Portal hypertension, e.g., cirrhosis of liver ➢ Hepatic outflow obstruction ➢ Portal vein thrombosis ➢ Alcoholic hepatitis ➢ Cardiac failure ➢ Myxedema ➢ Fatty liver of pregnancy ➢ Budd–Chiari syndrome ➢ Hepatic veno-occlusive disease ➢ Right-sided heart failure ➢ Constrictive pericarditis ➢ Massive liver metastasis	➢ Peritoneal tuberculosis ➢ Carcinoma involving peritoneal cavity ➢ Pancreatitis ➢ Nephrotic syndrome ➢ Biliary ascites ➢ Serositis (connective tissue disorders) ➢ Bowel infarction ➢ Bowel perforation

TABLE 6.42: Ascitic fluid changes in cirrhosis.

Features	*Findings*
➢ Appearance	➢ Clear, straw-colored or light green
➢ Specific gravity	➢ <1.018
➢ Protein	➢ <2.5 g/dL
➢ Total cell count	➢ Normal (<250/L)
➢ Differential cell count	➢ Mesothelial cells and lymphocytes
➢ Gram's stain	➢ Negative
➢ Culture	➢ Negative
➢ Malignant cells	➢ Absent
➢ Serum ascites albumin gradient (SAAG)	➢ 1.1 g/dL

Differential Diagnosis of Ascites (Table 6.43)

Nature of Ascitic Fluid

The ascitic fluid may be transudate or exudate. Differences between transudates and exudates are listed in **Table 6.44**.

TABLE 6.43: Examination of ascitic fluid and its interpretation.

Feature	*Interpretation*
Gross appearance	
Clear, straw-colored or light green	Cirrhosis, infective (e.g., tuberculosis, following intra-abdominal perforation), malignancy, chronic pancreatitis, heart disorders (congestive cardiac failure), constrictive pericarditis, hepatic vein obstruction (e.g., Budd–Chiari syndrome), Meigs syndrome (ovarian tumor), hypoproteinemia (e.g., nephrotic syndrome)
Hemorrhagic	Malignant tumors, tuberculosis, acute pancreatitis, ruptured ectopic pregnancy, trauma to abdomen
Cloudy, turbid	Bacterial peritonitis
Milky white (chylous)	Lymphatic obstruction (e.g., by carcinoma), cirrhosis
Specific gravity	<1.018 in transudates
	>1.018 in exudates
Protein	<2.5 g/dL in transudates
	>2.5 g/dL in exudates
Serum-ascites albumin gradient (SAAG)	*Refer* **Table 6.41**
Glucose	Low in malignancy, tuberculosis, peritonitis
Amylase activity	>1,000 units/L in pancreatitis
Microscopy	
Polymorphs	<250/mm^3 in cirrhosis
	>250/mm^3 in bacterial peritonitis
Lymphocytes	Tuberculosis, malignancy
Cytological examination	Malignancy
Special stains ➢ Gram's stain ➢ Ziehl–Neelsen staining	 Bacterial peritonitis Tuberculosis
Culture	
Pyogenic bacteria	Bacterial peritonitis
Mycobacteria	Tuberculosis

TABLE 6.44: Differences between transudative and exudative ascites.

Characteristics	*Transudate*	*Exudate*
Cause	Noninflammatory process	Inflammatory process
Mechanism	Ultrafiltrate of plasma, due to increased hydrostatic pressure with normal vascular permeability	Increased vascular permeability
Appearance	Clear, serous	Cloudy/turbid purulent/hemorrhagic/chylous
Color	Straw yellow	Yellow to red
Specific gravity	<1.018	>1.018
Protein	Low, <2 g/dL, mainly albumin	High, >2 g/dL
Clot	Absent	Clots spontaneously because of high fibrinogen
Cell count	Low (<250/μL)	High (>250/μL)
Type of cells	Few lymphocytes and mesothelial cells	Neutrophils in acute and lymphocytes in chronic inflammation
Bacteria	Absent	Usually present
Lactate dehydrogenase (LDH)	Low	High
Examples	Cirrhosis, nephrotic syndrome, heart failure	Peritonitis, malignancy

Causes: Various causes of ascites are listed in **Table 6.45**.

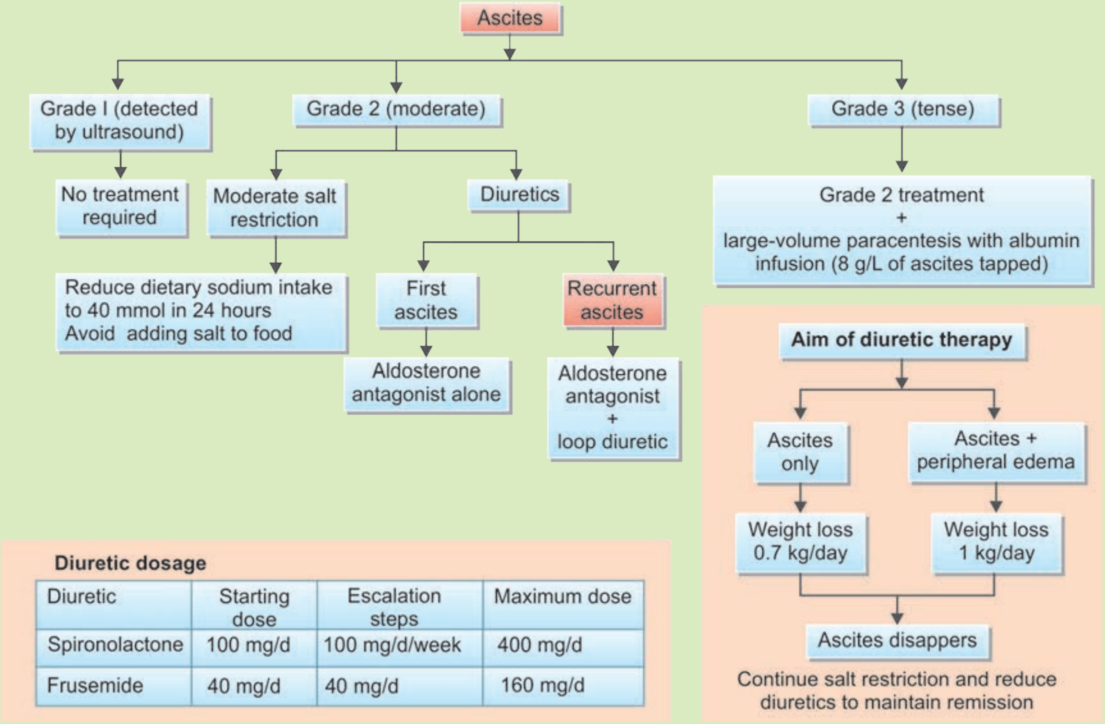
TABLE 6.45: Causes of ascites.

Cause	*Frequency (%)*	*Cause*	*Frequency (%)*
Parenchymal liver disease	78	**Renal**	1.5
Cirrhosis	77	Nephrotic syndrome Uremia Hemodialysis	
Fulminant liver failure	1	Pancreatic	1
Malignancy	12	Bacterial peritonitis	0.5
Cardiovascular disease ➢ Congestive heart failure ➢ Constrictive or restrictive cardiomyopathy ➢ Thrombosis of inferior vena cava ➢ Budd-Chiari syndrome ➢ Veno-occlusive disease	5	➢ Marked hypothyroidism ➢ Collagen vascular disease ➢ Familial mediterranean fever ➢ Amyloidosis ➢ Hereditary angioneurotic edema ➢ Menetrier's disease and protein-losing enteropathy ➢ Starch peritonitis ➢ Trauma	
Infection ➢ Tuberculosis ➢ Fitz-Hugh-Curtis syndrome (chlamydiae, gonococci) Coccidioidomycosis ➢ Whipple's disease (Tropheryma whipplei)	2		

Management

- **General measures:**
  - Hospitalization is necessary, if there is massive ascites.
  - Check serum electrolytes, renal function tests at the start of treatment and twice a week.
  - Weigh the patient daily. Measure abdominal girth and strict intake and output monitoring daily.
- **Bed rest** alone induces diuresis in a small proportion of people because renal blood flow increases in the horizontal position, but in practice is not helpful. Ascites treatment algorithm is shown in **Flowchart 6.6**.
- **Dietary restriction of sodium** by reducing sodium intake to 40 mmol in 24 hours and maintain an adequate protein and calorie intake with a palatable diet.
  - Patients with cirrhosis and ascites should have a moderately salt restricted diet with daily salt intake of no more than 5–6.5 g (87 mmol–113 mmol sodium). This translates to a no added salt diet with avoidance of precooked meals.
  - (Average Indian consumes—10.98 g/day of salt (regional variability)

FLOWCHART 6.6: Ascites treatment algorithm.



Ascites
Grade I (detected by ultrasound)
Grade 2 (moderate)
Grade 3 (tense)
No treatment required
Moderate salt restriction
Diuretics
Grade 2 treatment + large-volume paracentesis with albumin infusion (8 g/L of ascites tapped)
Reduce dietary sodium intake to 40 mmol in 24 hours Avoid adding salt to food
First ascites
Recurrent ascites
Aldosterone antagonist alone
Aldosterone antagonist + loop diuretic
Aim of diuretic therapy
Ascites only
Ascites + peripheral edema
Weight loss 0.7 kg/day
Weight loss 1 kg/day
Ascites disappers
Continue salt restriction and reduce diuretics to maintain remission
Diuretic dosage

Diuretic	Starting dose	Escalation steps	Maximum dose
Spironolactone	100 mg/d	100 mg/d/week	400 mg/d
Frusemide	40 mg/d	40 mg/d	160 mg/d

- First-line treatment of patients with cirrhosis and ascites consists of sodium restriction (88 mmol/day [2000 mg/day]) and diuretics (oral spironolactone with or without oral furosemide).
- Fluid restriction is not necessary unless serum sodium is less than 125 mmol/L.

- **Drugs:** Many contain significant amounts of sodium (up to 50 mmol daily). Examples include antacids, antibiotics (particularly the penicillins and cephalosporins) and effervescent tablets. Sodium retaining drugs (nonsteroidal, corticosteroids) should be avoided.
- **Fluid restriction to 1,000–1,500 mL/day** is necessary if the serum sodium is under 120 mmol/L.
- **Diuretics**
  - **Aim of diuretic therapy: To produce a net loss of fluid** of about 700 mL/day (0.7 kg weight loss in patients with ascites alone or 1.0 kg if both ascites and peripheral edema is present). The maximum rate at which ascites can be mobilized is 500–700 mL/day. This is to prevent diuretic-induced renal failure and/or hypernatremia.
  - Diuretics are administered in a step-wise manner.
  - **Aldosterone antagonists:** As there is **secondary hyperaldosteronism**, the diuretic of first choice is the one of the aldosterone antagonists (potassium-sparing diuretics), e.g., **spironolactone, triamterene, amiloride.** Spironolactone is started at a low dose of 25 mg QID (100 mg daily), and gradually stepped up every week to a maximum of 400 mg/day (providing there is no hyperkalemia). Chronic administration of spironolactone produces gynecomastia. **Eplerenone** 25 mg once daily does not produce gynecomastia.
  - **Loop diuretics:** When a large dose of spironolactone has failed, add a loop diuretic, such as **furosemide 20–40 mg or bumetanide 0.5 mg or 1 mg daily**. Usually spironolactone is combined with furosemide. Disadvantages of loop diuretics include development of hyponatremia, hypokalemia, and volume depletion.
  - **Stop all diuretics, if severe hyponatremia** (sodium <120 mEq/L), progressive renal failure or worsening of hepatic encephalopathy occurs. Vaptans may improve serum sodium in patients with cirrhosis and ascites.

Assessing diuretic response

Outpatient setting

- Assess atleast once a week
- Report early if alarm symptoms
- Reduction of weight less than 2 kg/week → increase dose
- Weekly creatinine/electrolytes
- Check for symptoms—fatigue, cramps, minimal hepatic encephalopathy (MHE)
- BP, orthostatic hypotension

Inpatient setting

- For grade 3 ascites—start combination
- Weight loss maximum 0.5 kg/day if ascites without edema and 1 kg/day if with edema
- Review dose every 48 hours
- Monitor labs/symptoms

When to reduce dose of diuretics?

- Complete response of edema feet
- Undetectable ascites on USG
- Weight loss more than 0.5 kg/day if ascites without oedema and 1 kg/day if with edema
- Postural hypotension
- Mild elevation of creatinine
- K <3.5 (furosemide), or >5.5 (spironolactone)

When to stop diuretics?

- SBP
- New onset HE
- Hypotension
- Rise in creatinine by 0.3 over baseline
- Sudden drop in urine output
- GI bleed
- Na <120

Treatment of Refractory Ascites

Q. Write short essay/note on indication, procedure, and complications of abdominal paracentesis.

Refractory ascites is defined as fluid overload that (1) is unresponsive to sodium-restricted diet and high-dose diuretic treatment (400 mg per day of spironolactone and 160 mg per day furosemide), or (2) recurs rapidly after therapeutic paracentesis.

They are managed on the following lines:

1. **Intravenous salt-poor albumin, 25 g in 3 hours**
2. **Oral midodrine 7.5 mg three times daily**
3. **Large-volume paracentesis**
   - **Indications (Box 6.26)**
   - **Procedure:**
     - Remove 3–5 L of fluid over 1–2 hours.
     - Salt-free albumin (8 g/L of ascetic fluid removed) if volume is more than 4–5 L is removed. If albumin is not available, dextran-70 may be used. Strict monitoring is necessary.

Box 6.26: Indications for large-volume paracentesis.

- Refractory ascites
- Used to relieve symptomatic tense ascites, e.g., cardiorespiratory distress due to gross ascites.
- Impending rupture of a hernia.

- **Complication:** Hypovolemic and renal dysfunction (postparacentesis circulatory dysfunction) more likely with removal of >5 L and worse liver function.

4. **Shunts:**
   - **TIPSS:** It is used for resistant ascites, if there is no spontaneous portosystemic encephalopathy and no disturbance of renal function.
   - **Le Veen shunt:** It is a peritoneovenous shunt that allows the peritoneal fluid to drain directly into the internal jugular vein.
5. Automated low-flow ascites pump (ALFApump)
   - Consists of a subcutaneously implanted battery-powered programmable pump.
   - It is connected to catheters that transfer ascites from the peritoneal cavity to the bladder, from which it is eliminated with urine
6. Slow low-dose continuous albumin, furosemide with or without terlipressin **SIFA(T)**infusion.
7. Liver transplantation.

Bacterial Peritonitis

Types: (1) Acute bacterial peritonitis or (2) chronic bacterial peritonitis.

1. Acute Bacterial Peritonitis

Causes: Appendicitis, perforated peptic ulcer or typhoid ulcer, cholecystitis, diverticulitis, gangrene of the small intestine and ulcerative colitis.

Symptoms

Fever, nausea, thirst, vomiting, severe abdominal pain. No flatus.

Signs

- Hippocratic facies
- Tachycardia, hypotension, and shock
- Board-like rigidity, tenderness, and rebound tenderness
- Absent peristaltic sounds.

Investigations

See **Box 6.27**

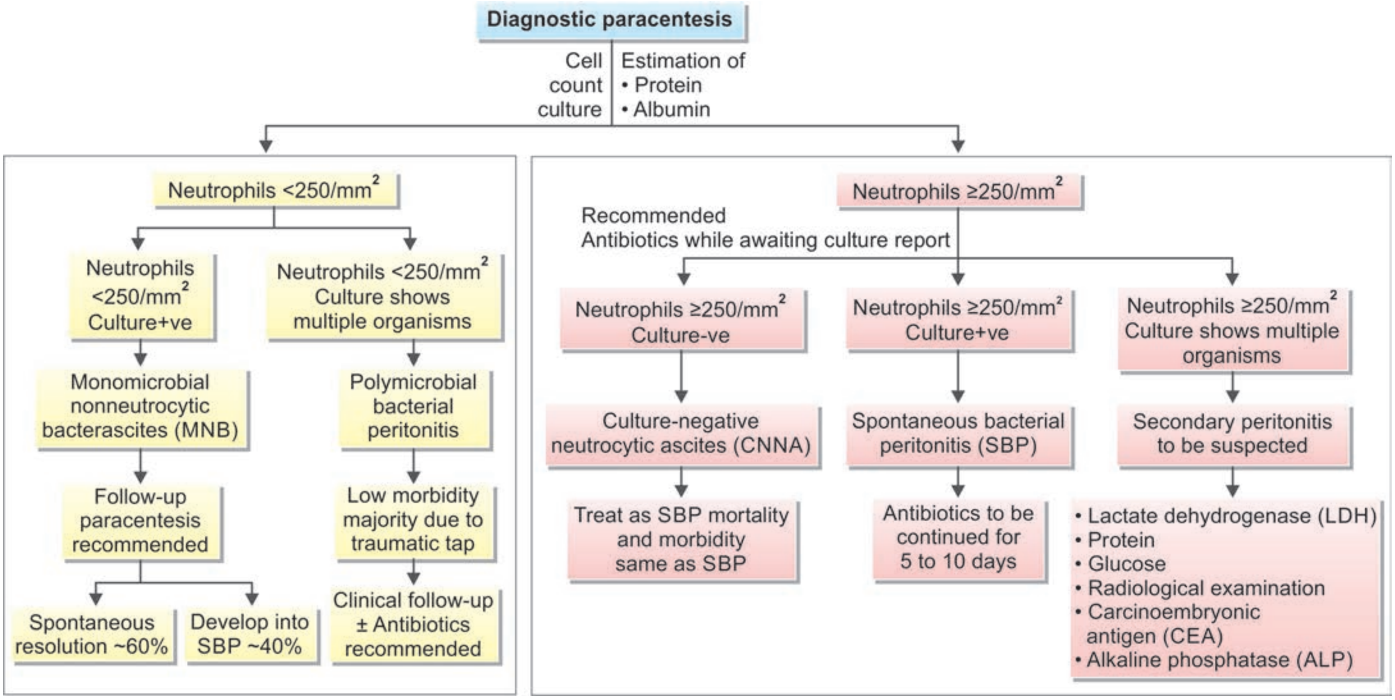
Box 6.27: Investigations in acute bacterial peritonitis.

- **Plain radiograph of abdomen**
  - Dilated loops of intestine
  - Gas under the diaphragm if there is intestinal perforation
- **Ascitic fluid (Flowchart 6.7)**
  - Exudate, turbid, or purulent
  - Shows intestinal contents in the fluid
  - Cell counts: Markedly increased, polymorphs > 250/mm^3
  - Gram stain: Positive for bacteria
  - Culture: It shows growth of organism.

Treatment: It is a surgical emergency.

- Correction of fluid and electrolyte balance
- Broad-spectrum antibiotic therapy
- Treat the shock
- Surgical treatment depending on the causes

FLOWCHART 6.7: Approach to the patient with ascites following diagnostic paracentesis.



Diagnostic paracentesis
Cell count culture
Estimation of • Protein • Albumin
Neutrophils <250/mm²
Neutrophils <250/mm² Culture+ve
Neutrophils <250/mm² Culture shows multiple organisms
Monomicrobial nonneutrocytic bacterascites (MNB)
Polymicrobial bacterial peritonitis
Follow-up paracentesis recommended
Low morbidity majority due to traumatic tap
Spontaneous resolution ~60%
Develop into SBP ~40%
Clinical follow-up ± Antibiotics recommended
Neutrophils ≥250/mm²
Recommended Antibiotics while awaiting culture report
Neutrophils ≥250/mm² Culture-ve
Neutrophils ≥250/mm² Culture+ve
Neutrophils ≥250/mm² Culture shows multiple organisms
Culture-negative neutrocytic ascites (CNNA)
Spontaneous bacterial peritonitis (SBP)
Secondary peritonitis to be suspected
Treat as SBP mortality and morbidity same as SBP
Antibiotics to be continued for 5 to 10 days
• Lactate dehydrogenase (LDH)
• Protein
• Glucose
• Radiological examination
• Carcinoembryonic antigen (CEA)
• Alkaline phosphatase (ALP)

2. Chronic Bacterial Peritonitis

- Associated with subacute intestinal obstruction
- Ascitic fluid: Exudate, protein is high, and contains a large number of chronic inflammatory cells.
- Classification of ascitic fluid infections is listed in **Box 6.28**.

Box 6.28: Classification of ascitic fluid infection.

- Culture-negative neutrocytic ascites
- Monomicrobial nonneutrocytic bacterascites
- Polymicrobial bacterascites (needle perforation of the bowel)
- Secondary bacterial peritonitis
- Spontaneous bacterial peritonitis

Treatment of the underlying cause.

Spontaneous Bacterial Peritonitis

Q. IM5.6, 5.16 Describe and discuss the pathophysiology, clinical evolution and management of spontaneous bacterial peritonitis.

Patients with cirrhosis and ascites are highly susceptible to infection of ascitic fluid.

Definition

Spontaneous bacterial peritonitis is a **common and severe complication of ascites** characterized by **spontaneous infection of ascitic without an evident intra-abdominal surgically treatable source**.

Pathogenesis

- **Causative agents***:* Most common organisms are *Escherichia coli, Klebsiella,* or enterococci, or other gut bacteria. Others include streptococci and enterococci.
- **Route of infection:** The infecting organisms in the gut flora traverse the intestine into mesenteric lymph nodes, leading to bacteremia and seeding of the ascitic fluid by hematogenous spread.

Clinical Features

- SBP should be **suspected in any patient with ascites who clinically deteriorates**.
- It may present as **sudden deterioration or hepatic encephalopathy in a cirrhotic patient with ascites.**
- Features include **fever, abdominal pain or discomfort and rebound abdominal tenderness** or they may present without any of these features.
- In terms of important predictors for identifying cirrhotic patients at greatest risk for SBP, both a high serum bilirubin (above 2.5 mg/dL) and a low ascitic fluid protein concentration (less than 1.0 g/dL) have been shown to be independent factors for both initial episodes of SBP as well as for recurrence.

Investigations

- **Peripheral blood: Leukocytosis.**
- **Ascitic fluid:**
    - **Cloudy fluid**
    - **Leukocyte count: More than $500/\text{mm}^3$**. A raised neutrophil count of $>250/\text{mm}^3$ in ascites is alone sufficient for diagnosis and to start treatment immediately.
    - pH: Less than 7.3.
    - **Culture: Positive**. Monomicrobial *E. coli* is the most common organism.
- Investigations to rule out abdominal sources of peritonitis by imaging.

Diagnosis

With **clinical suspicion, a diagnostic aspiration** (paracentesis) should always be performed in patients with GI bleeding, shock, fever, worsening liver and/or renal function, and hepatic encephalopathy for making the diagnosis.

Treatment

- **Third-generation cephalosporin:** Such as **cefotaxime or ceftazidime** being the most commonly used antibiotic. This is modified on the basis of culture results. Dose of cefotaxime: 2 g IV 8 hourly for 5 days.
- **Alternative therapy** in patients without shock or hepatic encephalopathy
    - **Amoxicillin/clavulanate** (1.2 g IV 8 hourly followed by 625 mg orally)
    - **Ciprofloxacin** (200 mg IV12 hourly followed by 500 mg BID orally)
    - **Ofloxacin** (400 mg twice daily).

Note: Quinolones should not be given if patient is on norfloxacin for prophylaxis.

- Antibiotic therapy and albumin (1.5 g/kg bodyweight within 6 hours of detection and 1 g/kg on day 3) reduces risk of type1 HRS.

Prophylaxis for SBP

Recurrence is common (70% within a year) and prophylaxis is indicated (**Box 6.29**).

- **Drugs:**
  - In **patients with upper GI hemorrhage: cefotaxime or norfloxacin** (400 mg BID for 7 days).
  - In **patients with low ascitic protein content** or previous episode of SBP: Long-term quinolones such as **norfloxacin** (400 mg/day lifelong).
  - Alternative but less effective drugs: Include cotrimoxazole (800 mg sulfamethoxazole + 160 mg trimethoprim once a day) or ciprofloxacin (750 mg once a week).

Tuberculous Peritonitis

Pathogenesis: Tuberculosis spreads to involve peritoneum by or more of the following sources:

- Through hematogenous seeding of peritoneum
- Through lymphatics or mesenteric nodes
- From genitourinary source

Box 6.29: Indications for prophylaxis for spontaneous bacterial peritonitis.

- **Patients with acute gastrointestinal bleeding** (antibiotic prophylaxis also reduces the rate of rebleeding)
- Patients with a **previous episode(s) of SBP** and recovered
- Patients with **low total ascites protein content** <1.5 g/dL or severe liver disease and no prior history of SBP

Clinical Features

- **Night sweats, weight loss, loss of appetite, malaise, and evening rise of temperature**
- Gradual abdominal distension and "**doughy feel" of the abdomen**.
- Multiple palpable masses in the abdomen produced due to matted omentum and loops of intestine.

Investigations (Table 6.46)

Treatment: Antituberculous chemotherapy.

TABLE 6.46: Investigations in tuberculous peritonitis.

Ascitic fluid	
➢ Usually straw colored ➢ **Protein: >2.5g/dL** ➢ **Lymphocytes >70%** ➢ **Ziehl–Neelsen staining:** It may show acid-fast bacilli	➢ Culture of ascitic fluid for tubercle bacilli ➢ Adenosine deaminase (ADA) levels: Raised ➢ **Peritoneal biopsy under laparoscopy**: Shows **granuloma** and helps in confirmation of diagnosis

Malignant Ascites

Causes

- Primary tumors of stomach, colon, ovary or other **intra-abdominal tumors may produce exudation fluid into the peritoneal cavity.**
- **Peritoneal metastasis:** From any primary.
- **Periumbilical subcutaneous metastatic tumor** deposits (known "Sister-Joseph's" nodules'), e.g., carcinoma of stomach.

Investigations

- **Ascitic fluid (Box 6.30)**
- **Biopsy of the peritoneum** by laparoscope: **It shows the tumor** and useful for confirmation of diagnosis.

Box 6.30: Ascitic fluid findings in malignant ascites.

- Appearance: **Exudate and hemorrhagic**
- **Protein: High**
- **Specific gravity: High**
- Microscopy: Sediment shows **malignant cells**.

Treatment: Palliative

- Repeated paracentesis.
- Intraperitoneal instillation of chemotherapeutic drugs: It may reduce rate of reaccumulation of ascites. The drugs include methotrexate, nitrogen mustard, or immunotherapy (interferon alfa).

Meigs Syndrome

Q. Write short note on Meigs's syndrome.

Features of Meigs's syndrome are presented in **Box 6.31**.

Box 6.31: Features of Meigs syndrome.

- Pleural effusion is most commonly **right sided**, may be exudate or transudate.
- **Ascites**
- **Pelvic tumor** (commonly fibroma of the ovary) in females. Both ascites and pleural effusion resolve following excision of the pelvic tumor.

Ascites Praecox

Q. What is ascites praecox?

- In ascites praecox, ascites occurs early and is disproportionately prominent as well as appears before the edema. It occurs in constrictive pericarditis, acute Budd–Chiari syndrome, tuberculous peritonitis, and malignant peritonitis.
- In constrictive pericarditis, ascites appears first, followed by edema. This sequence is one of the cardinal features, distinguishing ascites from congestive heart failure in which edema appears first and ascites much later. Edema is minimal in constrictive pericarditis and occurs in the later part of the disease.

Chylous Ascites

- Characterized by the **presence of chyle** (intestinal lymph) in the peritoneal cavity. Ascitic fluid is milky or creamy due to the presence of chylomicrons.
- **Causes:**
  - Injury/trauma to the main lymph ducts in the abdomen.
  - Malignancy (e.g., lymphoma) or tuberculosis causing obstruction of the intestinal lymphatics
  - Filariasis
  - Intestinal obstruction associated with rupture of a major lymphatic channel
  - Congenital lymph angiectasia
- **Clinical features:**
  - Acute abdominal pain with signs of peritoneal irritation
  - Distended, nontender, fluid filling the abdomen (chylous ascites).
- **Ascitic fluid:**
  - **Milky or creamy**
  - **High fat (triglycerides >1,000 mg/dL) content.**
  - **Sudan III staining demonstrates fat globules**.

DRUG AND TOXIN-INDUCED HEPATITIS

Q. IM5.7 Enumerate and describe the causes and pathophysiology of drug induced liver injury.

Types of drug-induced liver injury (DILI)

Variable	*Direct hepatotoxicity*	*Idiosyncratic hepatotoxicity*	*Indirect hepatotoxicity*
Frequency	Common	Rare	Intermediate
Dose-related	Yes	No	No
Predictable	Yes	No	Partially
Latency	Typically rapid (days)	Variable (days to years)	Delayed (months)
Common phenotypes	Acute hepatic necrosis, serum enzyme elevations	Acute hepatocellular hepatitis	Acute hepatitis, immune mediated hepatitis, fatty liver
Most common agents	High doses of acetaminophe, niacin, aspirin	Amoxicillin-clavunate, cephalosporins, macrolide antibiotics	Anti-neoplastic agents, glucocorticoids
Cause	Intrinsic hepatotoxicity when agent given in high doses	Idiosyncratic metabolic or immunologic reaction	Indirect action of agent on liver or immune system

DILI can also be classified as:

- Immune mediated (allergic)
- Non-immune mediated (non-allergic)

Case definitions for DILI:

- ≥5 × ULN elevation of ALT
- ≥2 × ULN elevation in ALP (particularly with accompanying elevation in concentrations of GGT in the absence of bone pathology driving the rise in ALP)
- ≥3 × ULN elevation in ALT and simultaneous elevation of TB exceeding 2 × ULN

$$R = \frac{\text{ALT} \div \text{ULN of ALT}}{\text{Alkaline phosphatase} \div \text{ULN of alkaline phosphatase}}$$

- $R \geq 5$ = Hepatocellular injury
- $R \leq 2$ = Cholestasis
- $R > 2$ and <5 = Mixed pattern of injury

	Immune mediated	*Non-immune mediated*
Latency period	1–6 weeks	1 month to 1 year
Fever, rash, eosinophilia	Yes	Uncommon
Reproduction of liver injury upon drug rechallenge	Yes	Uncommon
Dose related	No	May be

RUCAM (Roussel Uclaf causality assessment method) is an objective means of assessing causality that it is based on a numerical scoring system.

Hy's law

- ≥3 × ULN elevation of ALT or AST with >2 × ULN elevation of total bilirubin, without initial findings of cholestasis, indicated by elevated ALP.
- It is an indicator of severity.
- It is associated with a 10% higher risk of mortality.

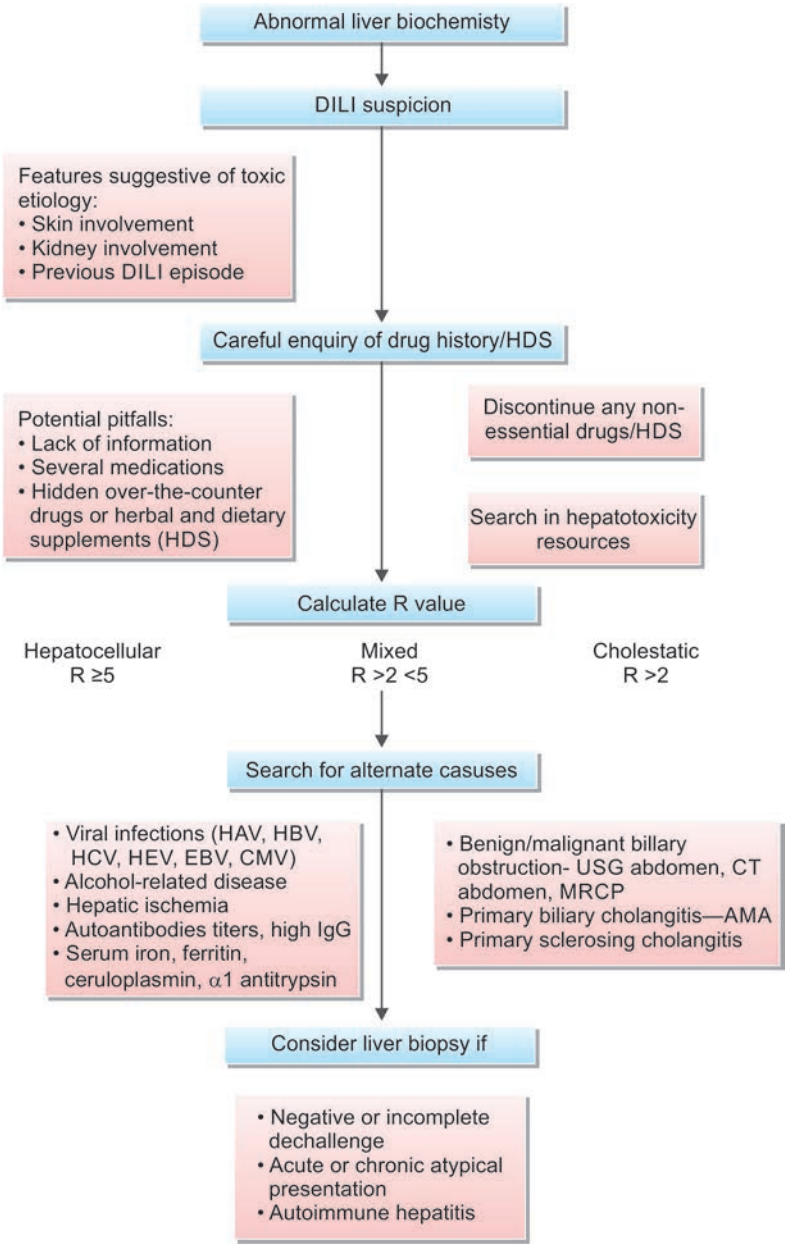
Clinicopathologic Classification of Drug-induced Liver Disease (Table 6.47)

TABLE 6.47: Clinicopathologic classification of drug-induced liver injury (DILI).

Category	***Implicated drugs: Examples***
Hepatic adaptation	Phenytoin, warfarin, rifampin, flavaspidic acid
Dose-dependent hepatotoxicity (necrosis)	Acetaminophen (paracetamol), nicotinic acid, amodiaquine, hycanthone, carbon tetrachloride, mushroom (*Amanita phalloides*), yellow phosphorus
Other cytopathic toxicity, acute steatosis	Valproic acid, didanosine, HAART agents, fialuridine, L-asparaginase, some herbal medicines
Acute hepatitis	Isoniazid, dantrolene, nitrofurantoin, halothane, sulfonamides, phenytoin, disulfiram, acebutolol, etretinate, ketoconazole, terbinafine, troglitazone, rifampicin, methyldopa, ibuprofen, ketoconazole, fluconazole, zidovudine, chlorothiazide, oxyphenisatin
Chronic hepatitis	Nitrofurantoin, etretinate, diclofenac, minocycline, nefazodone, phenytoin, isoniazid
Granulomatous hepatitis	Allopurinol, carbamazepine, hydralazine, quinidine, quinine, phenylbutazone, sulfonamides, allopurinol
Cholestasis without hepatitis	Oral contraceptives, androgens
Cholestatic hepatitis	Chlorpromazine, tricyclic antidepressants, erythromycin estolate, amoxicillin–clavulanic acid, methimazole, chlorpromazine, chlorpropamide, methyl testosterone, anabolic steroids, cyclosporine, nimesulide
Cholestasis with bile duct injury	Chlorpromazine, flucloxacillin, dextropropoxyphene
Chronic cholestasis	Chlorpromazine, haloperidol, erythromycin, cimetidine/ranitidine, nitrofurantoin, imipramine, azathioprine
Hepatic fibrosis	Methotrexate
Vanishing bile duct syndrome	Chlorpromazine, flucloxacillin, trimethoprim–sulfamethoxazole
Sclerosing cholangitis	Intra-arterial floxuridine, intralesional scolicidals
Steatosis (fatty change)	Zidovudine, amiodarone, indinavir, ritonavir, methotrexate, tetracyclines, valproic acid
Steatohepatitis	Perhexiline, amiodarone,
Vascular disorders	Contraceptive drugs, anabolic steroids, azathioprine
Tumors	Contraceptive pill, danazol

Treatment

- Discontinue the implicated agent.
- Spontaneous recovery after discontinuation is an important criteria in causality assessment.
- Specific therapy:
  - Cholestyramine is used to decrease the course of hepatotoxicity due to specific drugs such as leflunomide and terbinafine. Dose: 4 g every 6 hourly for 2 weeks.
  - Carnitine is used in valproate toxicity. Dose: 100 mg/kg IV over 30 minutes (maimum dose—6 g), followed by 15 mg/kg every 4 hourly until clinical improvement.
  - N-acetyl cysteine is used in paracetamol poisoning.
- Cholestatic DILI can be treated with UDCA at a dose of 13–15 mg/kg.
- Corticosteroids have not proven to be beneficial in idiosyncratic DILI unless accompanied by hypersensitivity features such as eosinophilia, rash, and fever.
- Any sign of acute liver failure requires prompt referral to a liver transplant center.



Abnormal liver biochemisty
DILI suspicion
Features suggestive of toxic etiology:
• Skin involvement
• Kidney involvement
• Previous DILI episode
Careful enquiry of drug history/HDS
Potential pitfalls:
• Lack of information
• Several medications
• Hidden over-the-counter drugs or herbal and dietary supplements (HDS)
Discontinue any non-essential drugs/HDS
Search in hepatotoxicity resources
Calculate R value
Hepatocellular R ≥5
Mixed R >2 <5
Cholestatic R >2
Search for alternate casuses
• Viral infections (HAV, HBV, HCV, HEV, EBV, CMV)
• Alcohol-related disease
• Hepatic ischemia
• Autoantibodies titers, high IgG
• Serum iron, ferritin, ceruloplasmin, α1 antitrypsin
• Benign/malignant billary obstruction- USG abdomen, CT abdomen, MRCP
• Primary biliary cholangitis—AMA
• Primary sclerosing cholangitis
Consider liver biopsy if
• Negative or incomplete dechallenge
• Acute or chronic atypical presentation
• Autoimmune hepatitis

HEPATIC VENOUS OUTFLOW TRACT OBSTRUCTION

Q. Discuss the etiology, clinical features, investigations, and management of hepatic venous outflow tract obstruction.

Q. Describe veno-occlusive disease or sinusoidal obstruction syndrome.

- Obstruction to the hepatic venous outflow can occur at different levels. These include:
  - Small central hepatic veins: Veno-occlusive disease
  - Large hepatic veins: Budd–Chiari syndrome
  - Inferior vena cava
  - Heart
- *Clinical features:* It depends on the cause and on the speed with which obstruction develops. Common features are congestive hepatomegaly and ascites.

Budd–Chiari Syndrome

Q. Explain briefly about Budd–Chiari syndrome.

- *Definition:* Budd–Chiari syndrome is characterized by obstruction of hepatic venous outflow owing to occlusion of the hepatic vein.
- *Level of obstruction:* It may be at any level from the small hepatic veins to the junction of the IVC with the right atrium.
- Classic Budd–Chiari syndrome results from thrombosis of one or more hepatic veins at their openings into the IVC.

Box 6.32: Various causes of Budd–Chiari syndrome.

Hepatic vein obstruction

Venous thrombosis

- Hypercoagulability states
    - Hematological disorders
    - Polycythemia vera
    - Paroxysmal nocturnal hemoglobinuria
    - Antithrombin III, protein C, or protein S deficiencies
    - Antiphospholipid syndrome
    - Sickle cell disease
    - Leukemia
    - Pregnancy
    - Use of oral contraceptive pills
    - Compression (may also produce thrombosis)
- Hepatic infections
- Hydatid cyst
- Liver abscess
- Obstruction due to tumors
- Renal cell carcinoma
- Adrenal tumors
- Hepatocellular carcinoma
- Posterior abdominal wall sarcomas

Radiation injury

Congenital venous webs

Trauma to the liver

Idiopathic (40–50% of cases)

Etiology

See **Box 6.32**

Clinical Features

Budd-Chiari syndrome: It comprises a triad of (1) abdominal pain, (2) ascites, and (3) hepatomegaly with hepatic histology showing centrilobular sinusoidal distension and pooling.

- Acute form (acute Budd–Chiari)
    - Follows sudden venous occlusion (e.g., by renal cell carcinoma, HCC, and polycythemia)
    - Acute upper abdominal pain, nausea, vomiting, tender hepatomegaly, marked ascites, and mild jaundice
    - With total venous occlusion: Delirium, coma, and hepatocellular failure
- Fulminant form (fulminant Budd–Chiari syndrome)
    - Presents with fulminant hepatic failure usually in the setting of an additional predisposing factor (e.g., factor V Leiden mutation)
    - Occurs particularly in pregnant women
- Chronic form (chronic Budd–Chiari)
    - More gradual occlusion and more usual presentation
    - Pain in abdomen, tender hepatomegaly, and gross ascites
    - Enlarged caudate lobe of the liver becomes palpable
    - Jaundice is mild or absent
    - Splenomegaly with portal hypertension
    - Negative hepatojugular reflux, i.e., pressure over the liver fails to fill the jugular veins.
    - Bilateral pedal edema and distended veins over abdomen, flanks, and back **(Fig. 6.27)** with IVC obstruction
    - Features of cirrhosis and portal hypertension in patients who survive the acute event
    - HCC may develop.

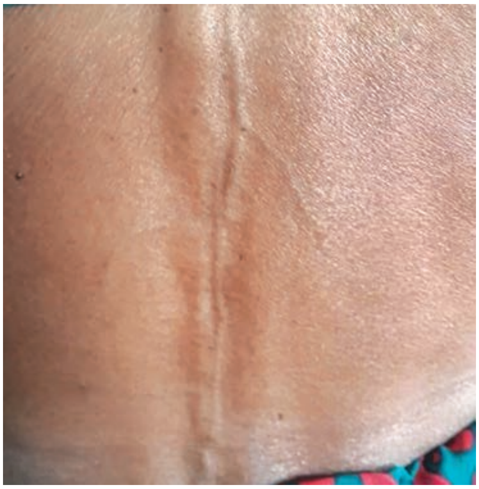


FIG. 6.27: Budd–Chiari dilated veins in back and lumbar region.

Investigations

- Liver function tests vary considerably.
    - Features of acute hepatitis: Mild hyperbilirubinemia, raised ALP, low serum albumin, and raised transaminases
- *Ascitic fluid examination:* Typically shows a high protein content (>2.5 g/dL, i.e. exudate) in the early stages; however, this often falls later in the disease.
- *Ultrasound*: It may show enlargement of the caudate lobe, intrahepatic collaterals, echogenic areas, and ascites. It also may show compression of the IVC, if present.
- *Pulsed Doppler sonography or a color Doppler:* It may show obliteration of the hepatic veins and reversed flow or associated thrombosis in the portal vein with high accuracy. This may be sufficient to establish the diagnosis. Doppler ultrasonography, with sensitivity and specificity rates >80%, is the diagnostic procedure of first choice.

- *Noninvasive CT or MRI:* It may also demonstrate occlusion of the hepatic veins and IVC with diffuse abnormal parenchyma on contrast-enhancement. It may also demonstrate enlargement of the caudate lobe which has independent blood supply and venous drainage.
- Hepatic venography is only necessary if CT and MRI are unable to demonstrate the hepatic venous anatomy clearly. It helps to determine extent of block and caval pressures.
- *Liver biopsy:* It shows centrilobular congestion hemorrhage, fibrosis, and cirrhosis depending on the duration of the disease.
- *Other investigations:* To identify a cause (e.g., blood tests and coagulation studies).

Management

- Predisposing causes should be removed or treated as far as possible.
- *In the acute situation with recent thrombosis:* Treated with thrombolytic therapy consisting of intrahepatic venous streptokinase (in very early cases of thrombosis), followed by heparin and oral anticoagulation (warfarin).
- *Short hepatic venous strictures:* Treated with angioplasty
- *Extensive hepatic vein occlusion:* Insertion of a covered TIPSS followed by anticoagulation may be useful in opening of the hepatic veins. Direct intrahepatic portocaval shunt (DIPS) is a modification of the TIPS procedure, using intravascular ultrasound-guidance, combined with fluoroscopy.
- *Ascites:* Initially treated medically with low-salt diet, diuretics as well as treating the underlying cause (e.g., polycythemia). If not relieved may be treated with surgical shunts such as Le Veen shunt and portosystemic shunts.
- Percutaneous balloon angioplasty is performed for membranous obstruction of the IVC and hepatic vein.
- Congenital web can be treated radiologically or resected surgically.
- Liver transplantation is indicated for chronic Budd–Chiari syndrome and for progressive liver failure, followed by lifelong anticoagulation.
- Without transplantation or shunting, particularly acute and fulminant types, are associated with poor prognosis.

Veno-occlusive Disease

Veno-occlusive disease (VOD), also known as sinusoidal obstruction syndrome, is a rare condition characterized by widespread occlusion of the small central hepatic veins.

Etiology

Develops as a complication of:

- Total body irradiation/myeloablative regimens are used before hematopoietic stem cell transplantation. It carries a high mortality.
- A variety of antineoplastic drugs have been implicated as causes of sinusoidal obstruction syndrome including gemtuzumab ozogamicin, actinomycin D, dacarbazine, cytosine arabinoside, mithramycin, and 6-thioguanine.
- Chronic immunosuppression with azathioprine or 6-thioguanine
- Ingestion of herbal teas made with pyrrolizidine alkaloids in Senecio and Heliotropium plants
- Ingestion of alkaloids in inadequately winnowed wheat or in "bush tea"
- Hepatic irradiation

Clinical Features

Clinical features are similar to those of the Budd–Chiari syndrome. Classically, sinusoidal obstruction syndrome manifests with mild hyperbilirubinemia (bilirubin levels >2 mg/dL), painful hepatomegaly, weight gain of >2%, and development of ascites.

Investigations

- Large hepatic veins appear patent radiologically. This is in contrast to Budd–Chiari syndrome.
- Transjugular liver biopsy (with portal pressure measurements) confirms diagnosis.
- Liver biopsy: Evidence of venous outflow obstruction.

Treatment

- Supportive and includes control of fluid overload, ascites, and hepatocellular failure.
- Defibrotide is a novel oligodeoxyribonucleotide with anti-ischemic, antithrombotic, and thrombolytic activity but minimal systemic anticoagulant effect. Several studies have shown efficacy of defibrotide in the prevention and treatment of sinusoidal obstruction syndrome with no major toxicity.

HEPATOCELLULAR CARCINOMA

Q. Discuss the etiology, clinical features, investigations, and management of hepatocellular carcinoma.

Hepatocellular carcinoma is the most common primary malignancy of liver from hepatocytes or their precursors. Predominantly in males with M:F ratio of 2.4:1. The number of men and number of women with HCC in the absence of cirrhosis are almost equal.

Etiology (Table 6.48)

Clinical Features

- Usually develops in patients with underlying cirrhosis
- **Nonspecific symptoms** Include ill-defined upper abdominal pain in the right hypochondrium, malaise, weakness, anorexia, fatigue, weight loss and ascites. Rapid development of these symptoms in a patient with cirrhosis is suggestive of HCC. Fever occurs due to tumor necrosis.
- On examination:
  - **Liver is enlarged, irregular, and nodular with pain or tenderness.**
  - **Friction rub or a hepatic bruit over the liver due to vascularity of tumor**
- Blood-tinged ascites, bone pain, and dyspnea due to metastasis.

TABLE 6.48: Risk factors for hepatocellular carcinoma.

Major risk factors	***Minor risk factors***	
Chronic hepatitis: HBV/HCV	Hereditary hemochromatosis	Oral contraceptives
Alcoholic cirrhosis	Wilson's disease	Cigarette smoking
Aflatoxin B_1 (a fungal toxin contaminating food)	Primary biliary cholangitis	Betel quid chewing
Nonalcoholic steatohepatitis (NASH)	Tyrosinemia	Thorotrast and arsenic exposure
	α1-antitrypsin deficiency	Obesity
	Glycogen storage disease	Ataxia telangiectasia
	Hormones: Anabolic steroids, estrogens and androgens	Hypercitrullinemia
		Acute intermittent porphyria
		Gallstones and cholecystectomy **>one in second column and other in third column**

(HBV: Hepatitis B virus; HCV: Hepatitis C virus)

Paraneoplastic Syndromes Associated with Hepatocellular Carcinoma (Table 6.49)

All patterns of HCCs have a strong tendency for invasion of vessels. The portal vein and its branches are infiltrated by tumor. Occasionally, long, snake-like tumor masses may **invade the portal vein** and occlude portal circulation. Rarely tumor may invade IVC and extend into the right side of the heart through the hepatic veins. It may metastasize to the lungs.

Investigations

- **Serum marker**
  - **Alpha-fetoprotein:** About 50% HCC is associated with high serum (>500 µg/L) or rising levels of alpha-fetoprotein. However, α-fetoprotein levels are often raised in other neoplastic and nonneoplastic liver diseases and in some extrahepatic disorders. AFP concentrations are normal in up to 40% of small HCCs.
  - **α-l-fucosidase:** It is raised in HCC and also in cirrhosis.
  - **Serum des-γ-carboxy prothrombin:** It is raised in a majority of HCC.
  - **Plasma microRNA** expression is also marker of HCC.
  - **Serum ALP: Very high.**
- Ultrasound scans show filling defects.
- CT scan **(triple-phase)** or MRI abdomen has 75–85% sensitivity in picking HCC. Hyperenhancement on late arterial phase images and washout at the portal venous and/or delayed phases of multiphasic contrast material-enhanced imaging are seen.
- **Hepatic artery angiography shows "tumor blushes."**

TABLE 6.49: Paraneoplastic syndromes associated with hepatocellular carcinoma.

Carcinoid syndrome	Porphyria
Hypercalcemia	Sexual changes—isosexual precocity, gynecomastia, feminization
Hypertrophic osteoarthropathy	Systemic arterial hypertension
Hypoglycemia	Thyrotoxicosis
Neuropathy	Thrombophlebitis migrans
Osteoporosis	Watery diarrhea syndrome
Polycythemia (erythrocytosis)	Dermatomyositis, pemphigus foliaceus, pityriasis rotunda

- Liver scintigraphic scans.
- **Liver aspiration or biopsy** particularly under ultrasonic guidance confirms the diagnosis.

Management/Treatment

Treatment is different for patients with cirrhosis and those without. Therapy depends on tumor size, multicentricity, extent of liver disease (Child–Pugh score) and performance status.

The Barcelona-Clínic Liver Cancer (BCLC) staging system

- Stage 0 with very early HCC are optimal candidates for resection.
- Stage A—early HCC are candidates for radical therapies (resection, liver transplantation or percutaneous treatments).
- Stage B—intermediate HCC—chemoembolization.
- Stage C—advanced HCC-new agents in the setting of clinical trials.
- Stage D—end-stage disease—symptomatic treatment
- **Surgical resection:** It is indicated when lesions 1–3 in number and <5 cm in size; without metastasis; with child score A. Local or segmental resections are preferred to major resections. After successful resection, tumor recurs in the cirrhotic liver in about 70% of patients after 5 years.
- **Nonsurgical therapy:** Majority of patients diagnosed in the advanced stage of HCC and cannot be treated by surgical resection. These patients can be treated by following nonsurgical therapy:
  - Local ablation strategies:
    - Radiofrequency ablation (RFA): Percutaneous RFA uses heat to kill tumor cells. A single electrode inserted into the tumor under CT or ultrasound guidance.
    - Transarterial embolization (TAE): Hepatic artery embolization with Gelfoam and doxorubicin
    - Transarterial chemo embolization (TACE): With drugs such as doxorubicin but is contraindicated in decompensated cirrhosis and when HCC is multifocal can be combined with RFA.
  - Local injection therapy: Numerous agents can be used for local injection into tumors and includes percutaneous ethanol injection (PEI) or percutaneous acetic acid injection (PAI). PEI causes not only direct destruction of tumor cells, but also destroy normal cells in the vicinity. It usually requires multiple injections (average three) and the maximum size of tumor treated is 3 cm.
  - Conventional chemotherapy and radiotherapy are unsuccessful.
  - Chemotherapy using sorafenib: This drug is a multikinase inhibitor with activity against RAF, VEGF, and PDGF signaling.
  - Nivolumab against programmed cell death 1 receptor (PD-1) has been used as immunotherapy.
- Liver transplantation: Indicated in presence of localized tumor and underlying advanced liver disease. Unfortunately, the underlying liver disease (e.g., hepatitis B and C) may recur in the transplanted liver.

Prognosis

Depends on size of tumor, the extent of spread (e.g., presence of vascular invasion), and liver function in those with cirrhosis.

LIVER TRANSPLANTATION

Q. Discuss briefly about liver transplantation.

Q. IM5.18 Enumerate the indications for hepatic transplantation.

- Transplantation of liver is useful in treating patient with end-stage liver disease or acute/fulminant liver failure and 5-year survival rate in good centers is about 75%.
- **"Split" livers:** In which one liver is used for two recipients. It is helpful in tackling organ shortage and in shortening the time on the waiting list.
- **Orthotopic liver transplantation:** It is the most common form of liver transplantation. Orthotopic means that the graft is placed in its correct anatomical location. In this technique, donor organ after removal of the native organ is transplanted in the same anatomic location.
- **Auxiliary partial orthotopic liver transplantation** (APOLT) is also called partial or split liver transplantation.
  - In this technique, a segment of donor liver is transplanted in a recipient who has undergone hemihepatectomy to make room for the graft.
  - **Advantage:** If the donor's liver fails, the recipient's own organ can function as a backup until a new liver is found.
- **Living donor liver transplantation:** In this technique, a portion of healthy person's liver is removed and used for transplantation.
  - **Living-related donors:** In this, the donor of the liver segment is a first-degree living relative.
- **Bioartificial liver:** Cultured hepatocytes are used in patients with acute liver failure till donor liver becomes available.

Indications (Table 6.50)

TABLE 6.50: Indications for liver transplantation.

Cirrhosis due to	*In children*
➢ **Acute/fulminant liver failure** (e.g., seronegative hepatitis, drug-induced liver injury) ➢ Chronic viral hepatitis C and B ➢ Alcoholic liver disease (after successful demonstration of abstention) ➢ Other causes of cirrhosis (e.g., nonalcoholic steatohepatitis, autoimmune diseases, primary biliary cholangitis)	➢ **Biliary atresia** ➢ **Inborn errors of metabolism:** Wilson's disease, glycogen storage diseases, Crigler–Najjar syndrome type I, familial hypercholesterolemia, α1-antitrypsin deficiency familial amyloid polyneuropathy, primary hyperoxaluria
➢ **Hepatocellular carcinoma** with no single lesion >5 cm or no more than three lesions with the largest being 3 cm or smaller. ➢ **Failure of previous liver transplant**	

Contraindications

- **Absolute contraindications**
  - Poor expected outcome of transplantation (e.g., multisystem organ failure, malignancy or infection of extrahepatic or extrabiliary tract, HCC with metastatic spread advanced cardiac or pulmonary disease, and HIV infection).
- **Relative contraindications**
  - Comorbidities that reduce survival (e.g., renal insufficiency, primary hepatobiliary malignancy >5 cm, hemochromatosis, SBP, patient older than 65 years).

Complications of Liver Transplantation (Table 6.51) and Immunosuppression (Box 6.33)

TABLE 6.51: Complications of liver transplantation.

Hepatic complications	*Nonhepatic complications*	
➢ Preservation-reperfusion injury with graft failure due to ischemia ➢ Acute graft rejection ➢ Surgical complications—relating to the anastomosis of bile duct and blood vessels such as failure or obstruction of biliary anastomosis.	➢ Chronic graft rejection ➢ Recurrent disease ➢ Infection and drug-induced liver injury ➢ Jaundice (due to blood transfusion, use of drugs and anesthetic agents, etc.).	➢ Infections/sepsis ➢ Fluid overload ➢ Renal dysfunction ➢ Intraperitoneal bleed

Box 6.33: Complications of immunosuppression.

- Infections
- Metabolic syndrome
  - Hypertension
  - Diabetes mellitus
  - Obesity
  - Dyslipidemia
  - Cardiovascular risk
  - Acute and chronic renal disease
  - Metabolic bone disease
  - De novo malignancy

PYOGENIC ABSCESS

Q. Discuss the etiology, clinical features, investigations, and management of pyogenic liver abscess (bacterial liver abscess).

Etiology

- Bacterial infections in the liver may be manifested as pyogenic abscess. The most common organism includes *E. coli, Streptococcus milleri, Klebsiella pneumoniae,* and *Bacteroides*. Other organisms include *Enterococcus faecalis, Proteus vulgaris,* and *Staphylococcus aureus*. Often the infection is mixed. Tuberculosis and melioidosis can present with liver abscess.
- **Route of infection:** The organisms may reach the liver through one of the following routes:
  1. **Portal vein:** Major source is intra-abdominal infections (e.g., appendicitis, diverticulitis, colitis and perforated bowel).
  2. **Arterial blood supply:** During systemic bacteremia, organism may reach liver via hepatic artery.
  3. **Ascending infection** in the biliary tract (ascending cholangitis).
  4. **Direct invasion** of the liver from a nearby source (e.g., subphrenic abscess, perinephric abscess), or a penetrating injury.

Clinical Features

- **Fever, chills, rigors, and right upper quadrant pain** radiating to right shoulder
- Weight loss, anorexia, nausea, and vomiting; can manifest as PUO
- Pleuritic chest pain

- **Tender hepatomegaly**
- Mild jaundice may develop when there is extrahepatic biliary obstruction.
- Respiratory findings at the base of right lung (pleural effusion and crepitations) or a pleural rub in the right lower chest.

Investigations

- **Serum bilirubin:** Raised in 25% of cases
- **Serum ALP:** Markedly elevated
- **Blood cultures:** Positive in only 30% of cases.
- **Normochromic normocytic anemia**, usually accompanied by a polymorphonuclear leukocytosis.
- **ESR and CRP** are often raised.
- **Chest radiograph:** Elevation of the right dome of diaphragm, and in severe cases right basilar atelectasis and pneumonia or effusion.
- **Ultrasonography** confirms the diagnosis.
- **CT scan of abdomen:** helpful when ultrasound is normal.
- **Needle aspiration of pus** for culture and sensitivity

Management

- **Antibiotics:** Initiate treatment with antibiotics (combination of ampicillin, gentamicin, and metronidazole) to cover gram-positive, gram-negative, and anaerobic organisms till the causative organism is identified. Later, change the antibiotic according to the culture and sensitivity reports. Duration of treatment is 4–8 weeks.
- **Ultrasound-guided aspiration of the abscess:** Indications are listed in **Box 6.34**.
- **Surgical drainage** via a large-bore needle for those who fail to respond **(Fig. 6.28)**.
- **Treat the underlying cause.**

Box 6.34: Indications for ultrasound-guided aspiration of liver abscess.

- Large abscess (>6 cm)
- Abscess in the left lobe
- Lack of response within 48-72 hours of medical therapy
- Ultrasonography suggestive of large abscess impending rupture

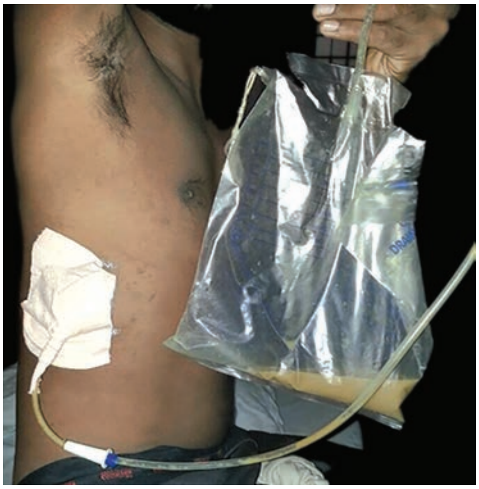

FIG. 6.28: Drainage of abscess with pig tail.

AMEBIC LIVER ABSCESS

Q. Write short essay/note on diagnosis and management of amebic liver abscess/hepatic amebiasis.

Liver involvement by *Entamoeba histolytica* produces amebic liver abscess. The term amebic hepatitis is not used at present.

Pathogenesis

- ***Entamoeba histolytica*** trophozoites from the base of an amebic ulcer in **colon** may reach liver **through the portal circulation.** The capillary system of the liver acts as an efficient filter and holds these trophozoites. **Trophozoites** multiply, **kill hepatocytes,** cause coagulation necrosis of the liver cells and produce single or multiple abscesses.
- Amebic abscess ranges from 8–12 cm in diameter and appears well circumscribed.

In most of the cases, the abscess is single and confined to the **posterosuperior aspect of the right lobe of the liver**. This is because right-lobe portal laminar blood flow is supplied predominantly by the superior mesenteric vein, whereas the left-lobe portal blood flow is supplied by the splenic vein. Abscess cavity is filled with a thick, dark brown, odorless, semisolid necrotic material, which resembles **anchovy paste (sauce) in color and consistency.**

Clinical Features

- Symptoms are similar to pyogenic abscesses (such as fever, anorexia, weight loss and malaise). Concurrent diarrhea is present in less than one-third of patients.
- **Insidious**/gradual **onset** with low-grade fever, sweats, malaise, weight loss, chills, and rigors. Few may have an acute-onset of fever. In later phase, there may be swinging temperature and sweating usually without marked systemic symptoms or associated cardiovascular signs.

- **Pain:** Patient may have pain in the right hypochondrium due to stretching of the liver capsule. Diaphragmatic irritation by abscess may cause referred pain in the right shoulder.
- Past history of dysentery may be present. Jaundice is rare.
- **Physical examination:** The patient looks ill, shows an enlarged, tender liver, intercostals point tenderness in the posterolateral of a lower right intercostals space (intercostal tenderness) and bulging of the intercostals spaces, upward extension of the liver dullness on percussion. There may be signs of an effusion or consolidation in the base of the right side of the chest.

Complications

1. **Due to rupture of abscess:**
   - Spontaneous external rupture may produce "granuloma cutis.
   - Rupture into bronchus may result in expectorates large amounts of the typical "anchovy-sauce" pus
   - Rupture into pleural space may produce massive pleural effusion
   - Rupture into peritoneal cavity may produce peritonitis
   - Rupture below the diaphragm to produce subdiaphargmatic abscess
   - Rupture into stomach
   - Abscess in the left lobe of liver may rupture into pericardium resulting in pericarditis and rarely cardiac tamponade.
2. **Due to direct extension** into lung, it may produce amebic lung abscess.
3. **Due to hematogenous spread:** Metastatic brain abscess, splenic abscess

Diagnosis

- **Blood:** Polymorphonuclear leukocytosis is a characteristic finding.
- **Liver function tests:** May be abnormal.
  - Most consistent abnormality is raised ALP.
  - Level of AST reflects the severity of the disease. Jaundice is uncommon, and its presence is indicative of a grave prognosis.
- **Chest radiography:** Demonstrate abscess (a raised right hemidiaphragm on chest X-ray). Other findings include right-sided pleural effusion and right basal pneumonitis.
- **Ultrasound:** Ultrasonic scanning of liver is very useful for establishing the diagnosis and localization of the abscess. The defect produced by abscess in the liver usually persists for several months after the complete recovery of the patient.
- **Isotope liver scans and computed tomography:** Can also assist to detect abscess.
- **Serologic tests:** For ameba, include indirect hemagglutination test, amebic complement fixation test, ELISA or counter immunoelectrophoresis which can detect antibodies in the blood and are more useful in amebic liver abscess.
- **Amebic fluorescent antibody test:** It is positive in about 90% of patients with liver abscess and in 60–70% with active colitis. **Nested-multiplex PCR** has a sensitivity of 75–100%.
- **Aspiration of amebic liver abscess:** Needle aspiration yields the characteristic "anchovy-sauce" or "chocolate-brown" pus (**Fig. 6.29**). The pus is usually thick in consistency, yellow or green in color, and characteristically odorless. It consists of liquefied necrotic liver tissue and does not contain polymorphonuclear leukocytes. As the parasites are localized in the abscess wall, pus may not show free amebae. Ameba may be demonstrated in the terminal portion of the aspirate, or by a needle biopsy of the abscess wall.

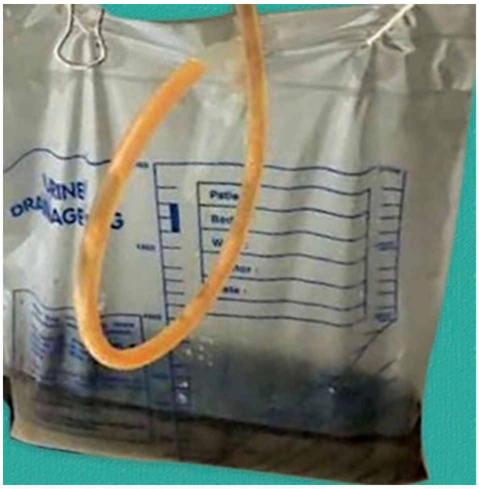

FIG. 6.29 : Anchovy-sauce appearance of amebic abscess.

Treatment

- **Metronidazole** 800 mg three times daily for 7–10 days or **tinidazole** 2 g orally daily as a single dose for 5 days is usually adequate in liver abscess. Severe cases may need intravenous administration of metronidazole (500 mg 8 hourly).
- **Chloroquine:** It may be given at a dose of 300 mg twice daily for 2 days, followed by 150 mg twice daily for another 19 days. It is usually administered to those patients who do not respond adequately to metronidazole.

- **Emetine and dehydroemetine** are lethal to the trophozoites of *E. histolytica*. However, because of their toxicity, they are rarely used. Dehydroemetine is less toxic than emetine. Toxicity includes cardiac arrhythmias, muscle weakness, vomiting precordial pain, and diarrhea.
- **Therapeutic aspiration of the abscess:** If a liver abscess is large or likely to burst, or if the response to chemotherapy is not prompt, aspiration is required and repeated if required. Rupture of an abscess into the pleural cavity, pericardial sac or peritoneal cavity needs immediate aspiration or surgical drainage.
- **Percutaneous drainage:** It is achieved by placing a large-bore catheter into the abscesses for draining the abscess. It is usually performed when therapeutic aspiration fails and its indications are:
  - Large abscess and associated risk of spontaneous rupture (especially left-lobe abscesses)
  - If abscess is ruptured already (drainage of both abscess and extraneous collection)
  - Absence of response to medical therapy with signs of persistent sepsis or enlarging abscesses or persistent symptoms
  - Evidence of liver failure
- **After treatment** of the invasive disease, luminal amebicide such as diloxanide furoate 500 mg orally TID for 10 days; or aminosidine (paromomycin) 25–35 mg/kg/day orally in three divided doses for 7–10 days should be given to clear luminal cysts or parasite. Alternative agents include iodoquinol 650 mg orally TID for 20 days, and nitazoxanide.

Clinical comparison between pyogenic and amebic liver abscess (**Table 6.52**)

TABLE 6.52: Pyogenic and amebic liver abscess: clinical comparisons.

Parameter	*Pyogenic liver abscess*	*Amebic liver abscess*
Number	Often multiple	Usually single
Location	Either lobe of liver	Usually right hepatic lobe, near the diaphragm
Presentation	Subacute	Acute
Jaundice	Mild	Moderate
Diagnosis	US or CT-guided aspiration	US or CT and serology

(CT: Computed tomography; US: Ultrasound)

METABOLIC LIVER DISEASE

Iron Overload

Q. What are various disorders associated with iron overload?

Q. Discuss the etiology, pathology, clinical features, investigations, and management of hereditary (primary) hemochromatosis ("bronze diabetes").

Classification of Iron Overload (Box 6.35)

In secondary iron overload, iron accumulates in Kupffer cells rather than hepatocytes compared to that of hereditary hemochromatosis.

Box 6.35: Classification of iron overload.

Hereditary
- Mutations of genes encoding HFE, transferrin receptor 2 (TfR2), or hepcidin
- Mutations of genes encoding hemojuvelin (HJV)
- Hemosiderosis (secondary hemochromatosis)
- Parenteral iron overload
  - Exogenous: Multiple blood transfusions, repeated iron injections, long-term hemodialysis
  - Endogenous: Sickle cell disease
- Ineffective erythropoiesis with increased erythroid activity: β-thalassemia, sideroblastic anemia, porphyria cutanea tarda
- Increased oral intake of iron
- Chronic liver disease: Chronic alcoholic liver disease

Hereditary Hemochromatosis

- Hereditary hemochromatosis (HH) is an inherited **autosomal recessive** disorder characterized by **abnormal (excessive) accumulation of iron** in various parenchymal organs leading to eventual fibrosis and functional organ failure.
- In symptomatic patients of hemochromatosis, the total body iron is increased to 20–40 g, compared with 3–4 g in normal individuals.
- Associated with **high incidence of HCC**
- Most of the hereditary hemochromatosis is inherited as autosomal recessive genetic disorder and associated with HLA-B3, B7 and B14 histocompatibility antigens.

Pathology

The **excess iron is deposited** commonly in the **liver, joint, heart, pancreas, endocrine glands** (e.g., pituitary gland) **and skin**.

Clinical Features

- **Age and gender:** Overt clinical manifestations occur **more frequently in males** over the age of 40 years. About 90% of the patients are males. Females are protected because of loss of iron during menstruation and pregnancy.
- **Symptoms:**
  - It may develop due to toxic damage of cells by accumulated iron and consequent fibrosis.

- Symptoms may be **vague**-muscle aches, weakness, abdominal and/or joint pain.
- **Classic triad:** Consists of **bronze skin pigmentation** (**Fig. 6.30**) (due to melanin deposition in exposed parts, axillae, groins and genitalia), **hepatomegaly and diabetes** mellitus (**"bronzed diabetes"**) is observed in patients with gross iron overload.
- **Late features:** Hypopituitarism, loss of libido, testicular atrophy, cardiac complaints (cardiomyopathy, heart failure and cardiac arrhythmias), hypothyroidism, cirrhosis with hepatosplenomegaly, spiders, loss of body hair, jaundice, and ascites.

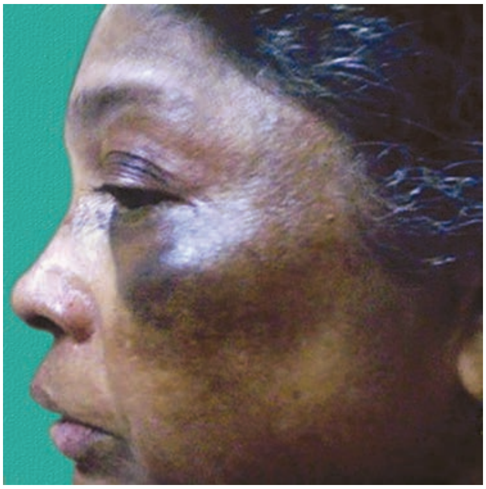

FIG. 6.30: Skin pigmentation in hemochromatosis.

Complications

- **Chondrocalcinosis:** Develops due to asymmetrical deposition of calcium pyrophosphate in both large and small joints and leads to an arthropathy. It has characteristic radiologic findings: Squared-off bone ends and hook-like osteophytes in the second and third metacarpophalangeal (MCP) joints.
- **Hepatocellular carcinoma** in 30% of patients with cirrhosis
- **Multi-organ failure**
- Susceptibility to specific infections (bacteria whose virulence is increased in the presence of excess iron). These include *Listeria monocytogenes, Yersinia enterocolitica,* and *Vibrio vulnificus.*

Investigations

- **Serum iron profile:**
  - **Serum iron** is **elevated** (>30 μmol/L).
  - **Total iron binding capacity (TIBC): Reduced**
  - **Fasting transferrin saturation** (serum iron divided by the total iron binding capacity) **is high (>45%)** which is **highly sensitive for diagnosis.**
  - **Serum ferritin is elevated** (usually >500 μg/L or 240 nmol/L). It is less sensitive than transferrin saturation in screening for hemochromatosis because it is also increased in alcoholic liver disease, hepatitis C infection, NASH. It is also an acute-phase reactant and increased in other inflammatory and neoplastic conditions.
- **Biochemical tests** for liver function are **often normal**, even with established cirrhosis.
- **Genetic testing:** It is performed if iron studies are abnormal.
- **CT scan:** Shows **increased density of liver** due to deposits of iron.
- **Magnetic resonance imaging (MRI):** It is **sensitive** to detect liver iron content.
- **Liver biopsy:** Not necessary for diagnosis. It shows **iron deposition** and hepatic **fibrosis** leading on to cirrhosis.
- **Screening**: All first-degree family members of hereditary hemochromatosis must be screened to detect early and asymptomatic disease.

Treatment and Management

- Treatment **should be started before permanent organ damage** occurs due to iron toxicity. The excess iron should be removed as rapidly as possible and prolongs life and may reverse tissue damage.
- **Phlebotomy/Venesection:** Venesection of 500 mL blood (removes 250 mg of iron) is performed twice-weekly until the serum iron is normal. This may take 2 years or more.
- **Chelation therapy:** Rarely in patients who cannot tolerate venesection because of severe cardiac disease or anemia, chelation therapy with **desferrioxamine** can be used. Dose is 40–80 mg/kg/day subcutaneously. It removes about 10–20 mg of iron/day. Deferiprone and deferasirox are other chelators.
- **Erythrocytapheresis** is an apheresis technique whereby red cells are removed in an isovolemic manner and the patient's plasma is returned to the patient, larger amounts of iron can be removed per session than by phlebotomy.
- Treatment of diabetes
- Treatment of cirrhosis: There is a risk of malignancy if cirrhosis is present
- Treatment of congestive heart failure and cardiac arrhythmias
- **Dietary limitations:** (i) Dietary iron intake to be restricted, (ii) agents for reducing iron absorption (tannates in tea, phytates, oxalates, calcium, and phosphates) to be used, (iii) avoidance of excessive ethanol, (iv) avoidance of ascorbic acid (vitamin C) supplements, and (v) avoidance of uncooked seafood.

Wilson's Disease

Q. Discuss the etiology, pathology, clinical features, investigations, and management of Wilson's disease (hepatolenticular degeneration).

Q. Explain in brief about Kayser-Fleischer ring.

- **Wilson's disease (progressive hepatolenticular degeneration)** is a **very rare inborn error of copper metabolism** characterized by **increased total body copper.**
- Excess **copper deposition** in various organs: **(1) liver, (2) basal ganglia of the brain, (3) cornea, (4) kidneys, and (5) skeleton**.
- **Potentially treatable** condition.

Etiology

- **Autosomal recessive** disorder
- Consanguinity is risk factor.
- **Molecular defect within a copper-transporting ATPase** encoded by a gene (***ATP7B***) located on chromosome 13. More than 300 mutations have been identified and is rare in India and Asia.
- **Defect:** Excessive accumulation of copper in the body due to:
  - Failure of incorporation of copper into proceruloplasmin and leads to **low serum ceruloplasmin.**
  - Failure of biliary copper excretion, causing its accumulation in the body.

Pathology

Liver: Microscopic features are **not diagnostic** and vary from that of **chronic hepatitis to macronodular cirrhosis**. Stains for copper show a periportal distribution of copper.

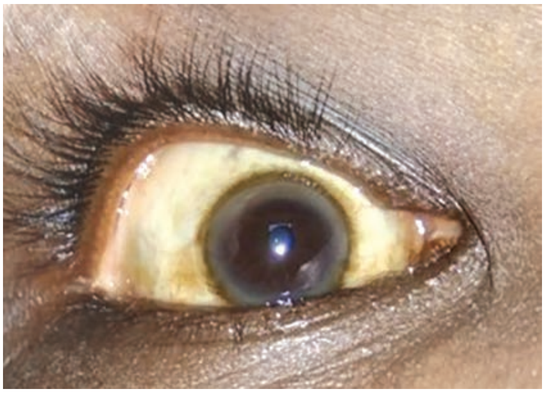

FIG. 6.31: Kayser–Fleischer ring.

Clinical Features

- **Age of presentation** is usually between **5 and 30 years**.
  - Children usually present with hepatic problems.
  - Young adults usually present with more neurological problems.
- **Features of liver involvement:** Varies from (1) acute hepatitis going on to, (2) fulminant hepatic failure to, (3) chronic hepatitis, or (4) cirrhosis.
- **Features of brain involvement: Dysarthria,** involuntary movements, tremors (especially asymmetric, resting and intention tremors, wing beating), **ataxia,** and eventually dementia.
- **Psychiatric manifestations:** Phobia, depression, compulsive behavior.

Kayser–Fleischer rings

- It is a **characteristic sign** due to deposition of **copper in the Descemet's membrane** of cornea.
- Appears as **greenish-brown or golden-brown ring at the corneoscleral junction** (around the periphery of the cornea), appearing first at the upper periphery gradually disappear with effective medical treatment or liver transplantation.
- Best identified by slit-lamp examination
- It may be absent in young children and disappears with treatment.
- May be associated with "sunflower cataracts."
- **Kayser–Fleischer rings (Fig. 6.31) are not specific for Wilson's disease**; they are found occasionally in patients with other types of chronic liver disease, usually with a prominent cholestatic component, such as PBC, primary sclerosing cholangitis, or familial cholestatic syndromes, and rarely in patients with nonhepatic diseases.

Other manifestations: Kidney (renal tubular damage), skeleton (osteoporosis, arthropathy).

Investigations

- **Slit-lamp examination** of the eyes for Kayser–Fleischer ring
- **Serum copper: Reduced** but can be normal.
- **Serum ceruloplasmin levels: Low** and less than 20 mg/dL.
- **Urinary copper: Usually increased** 100–1,000 μg in 24 h (1.6–16 μmol); normal levels <40 μg (0.6 μmol). The **penicillamine challenge:** 500 mg dose of penicillamine at the beginning of the 24-hour urine collection and then again at 12 hours. Urinary copper excretion greater than 1,600 mg per 24 hours (>25 μmol) is diagnostic.

- **Liver biopsy:** Gold standard. Diagnosis depends on the amount of copper in the liver (>250 µg/g dry weight).
- **Hemolysis and anemia** may be found.

Treatment and Management

- Treatment should be started early and will show improvement both clinically and biochemically.
- **Chelating drugs:**
  - **Penicillamine with pyridoxine:** It should be given lifetime in the dose of 1–1.5 g daily and effectively chelates copper.
- For asymptomatic cases and maintenance therapy (after maximal improvement with penicillamine)
  - **Trientine dihydrochloride:** In the dose of 1.2–1.8 g/day
  - **Zinc acetate:** Indicated in chronic hepatitis and cirrhosis. Dose 150 mg/day. It blocks absorption of copper from intestine. However, it **should not be administered with penicillamine or trientine** since both these drugs chelate zinc.
  - **Other drugs:** (1) intramuscular **dimercaprol,** (2) **ammonium tetrathiomolybdate,** (3) **potassium sulfide, and** (4) **carbacrylamine resins**.
  - **Liver transplantation:** In fulminant hepatic failure and decompensated/advanced cirrhosis
  - All siblings and children of the patient should be screened for Wilson's disease and treated even if they are asymptomatic, and if there is evidence of copper accumulation.

α1-Antitrypsin Deficiency

Q. Write a short note on α1-antitrypsin.

Clinical Features

- In neonates, it produces cholestatic jaundice
- **In adults:**
  - **Liver: Chronic hepatitis, cirrhosis, HCC, and cholangiocarcinoma**
  - **Lung: Emphysema, chronic bronchitis**
  - **Others:** Panniculitis, vasculitis, pancreatitis, and glomerulonephritis

Investigations

- **Serum α_1-antritrypsin is low** (normal above 150 mg/dL).
- **Serum protein electrophoresis** shows **absence of $\propto_1$-globulin peak**.
- **Liver biopsy:** α_1-AT accumulates in periportal hepatocytes and can be seen as **periodic acid-Schiff (PAS)-positive, diastase-resistant globular inclusions** in these **hepatocytes**. The injury to these hepatocytes results in progressive fibrosis and cirrhosis.

Treatment

- **No treatment** apart from dealing with the complications of liver disease.
- Stop cigarette smoking and alcohol intake.
- Liver or lung transplantation.

Biliary Cirrhosis

Q. What is biliary cirrhosis? Discuss the etiology, pathology, clinical features, investigations, and management of primary biliary cholangitis.

- It is a type of **cirrhosis** of the liver **secondary to prolonged obstruction of biliary system** (anywhere between the small interlobular bile ducts and the papilla of Vater).
- Obstruction results in progressive destruction of bile ducts.

Classification

Biliary cirrhosis may be subdivided into PBC and secondary biliary cirrhosis.

1. **Primary biliary cholangitis:** It is a probably an **autoimmune disorder** of the intrahepatic biliary tree.
2. **Secondary biliary cirrhosis:** It is due to **prolonged obstruction of the extrahepatic biliary tree**.

Primary Biliary Cirrhosis Presently called as Primary Biliary Cholangitis

- **Gender:** It usually affects **middle-aged women**, with a female to male ratio of more than 6:1.
- **Age:** Peak incidence between **40 and 50 years** of age (perimenopausal).

Etiology and Pathogenesis

- PBC is thought to be an **autoimmune disorder**, but its exact pathogenesis is not known.
- **Genetic and environmental** factors play role in the pathogenesis of the PBC. Probably an environmental factor acts on a genetically predisposed individual via molecular mimicry initiate autoimmunity.

Clinical Features

- It is **insidious i**n onset and asymptomatic patients are discovered during routine examination or investigations.
- Commonly present with **pruritus** (often the earliest symptom), **fatigue, and skin pigmentation** (due to melanin deposition) abdominal discomfort.
- **Features of liver involvement:**
    - **Intense pruritus** (probably due to bile salts) occurs months to years before jaundice and is more at night. Scratch marks.
    - **Progressive jaundice (bottle green color)**
    - **Clubbing** of fingers
    - Hepatosplenomegaly
    - Hepatic decompensation, portal hypertension, ascites and variceal bleeding develop.
- **Hypercholesterolemia:**
    - **Xanthelasmas** (cholesterol-rich macrophages) around the eyes **(Fig. 6.32)**
    - **Xanthomas** over joints, tendons, hand creases, elbows, and knees
    - Pain, tingling, and numbness over feet and hands due to peripheral neuropathy produced by lipid infiltration of peripheral nerves.

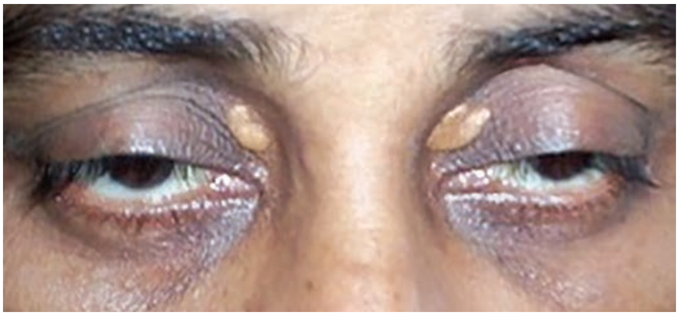

FIG. 6.32: Xanthelasmas around the eyes.

- **Malabsorption**
    - Steatorrhea and diarrhea due to malabsorption of fat
    - Easy bruising and ecchymosis due to vitamin K deficiency
    - Osteomalacia and/or osteoporosis due to malabsorption of vitamin D
    - Night blindness due to vitamin A deficiency
    - Dermatitis due to vitamin E deficiency
- **Extrahepatic manifestations:** These include autoimmune disorders such as Sjögren syndrome, keratoconjunctivitis sicca (dry eyes and mouth), systemic sclerosis, autoimmune thyroiditis, rheumatoid arthritis, Raynaud phenomenon, membranous glomerulonephritis, and celiac disease.

Investigations

- **Antimitochondrial antibodies** are characteristic and are essential for the diagnosis of PBC. They are found in 90–95% of patients. M2 antibody is specific. Other nonspecific antibodies (e.g., **antinuclear factor** and smooth muscle) may also be present.
- **Marked rise of serum 5′-nucleotidase** activity
- **High serum ALP** (markers of cholestasis)**:** Two-to five-fold rise
- **Hyperlipidemia and serum cholesterol** is **raised.**
- **Serum bilirubin:** Hyperbilirubinemia of the conjugated type occurs in late stages.
- **Serum transaminase:** Mild elevation of transaminases.
- **Serum IgM** may be **very high**.
- **Ultrasound:** It shows diffuse alteration in liver architecture.
- **MRCP (or ERCP):** It shows normal biliary tree.
- **Liver biopsy:** Portal tract infiltration by lymphocytes and plasma cells and about 40% have granulomas. Later portal tract fibrosis and, eventually progress to cirrhosis.

Note: Hepatic granulomas are not specific and are also found in sarcoidosis, tuberculosis, schistosomiasis, drug reactions, brucellosis, parasitic infestation (e.g., strongyloidiasis) and other conditions.

Management/Treatment

- **Ursodeoxycholic acid (10–15 mg/kg):** It improves bilirubin and aminotransferase levels. It should be started early in the asymptomatic phase.
- **Steroids:** They improve biochemical and histological disease but may lead to increased osteoporosis.

- **Other therapies** include azathioprine, colchicines, and methotrexate and cyclosporine may be beneficial in few patients.
- **Steatorrhea:** It is treated by limiting intake of fat and substituting long-chain triglycerides with medium-chain triglycerides in the diet.
- **Malabsorption of fat-soluble vitamins** (A, D, and K) is managed **by supplementation.**
- Calcium supplementation
- **Pruritus** is difficult to control but following can be helpful.
  - **Cholestyramine** one 4 g sachet three times daily, but is unpalatable
  - Antihistamines
  - Rifampicin, naloxone hydrochloride, ondansetron, and opiate antagonists (naloxone and naltrexone)
- Liver transplantation

Complications: These include (i) cirrhosis, (ii) osteoporosis and osteomalacia, (iii) polyneuropathy, and (iv) increased risk of HCCs.

Secondary Biliary Cirrhosis

Q. Write short note on secondary biliary cirrhosis.

Definition

Cirrhosis developing **secondary to prolonged** (for months) **obstruction** of the extrahepatic (large biliary duct) biliary tree.

Causes of Obstruction

(1) Gallstones, (2) bile duct strictures, and (3) sclerosing cholangitis
Patients with malignant tumors of bile duct or pancreas rarely survive long enough to develop secondary biliary cirrhosis.

Cardiac Cirrhosis

Q. Write a short note on cardiac cirrhosis.

- **Cause:** Liver damage primarily due to congestion may develop in all types of **right heart failure.** Examples: valvular heart disease, constrictive pericarditis, or cor pulmonale of long duration (more than 10 years).
- **Mechanism:** Right heart failure causes retrograde transmission of raised venous pressure via the IVC and hepatic vein into the liver. This leads to passive congestion of liver. When passive venous congestion becomes chronic/prolonged, the liver becomes enlarged, tender and shows a "nutmeg appearance" (alternating red-congested and pale-fibrotic areas). Very rarely, prolonged, severe right-sided heart failure and hepatic congestion cause cardiac cirrhosis.
- **Clinical features**
  - Usually dominated by the heart disease
  - Symptoms and signs of severe right heart failure.
- **Diagnosis**
  - Firm enlarged liver with signs of chronic liver disease in a patient with valvular heart disease, constrictive pericarditis, or chronic cor pulmonale.
  - Nonpulsatile liver despite the presence of tricuspid regurgitation
  - Liver biopsy confirms the diagnosis (not required in most cases).

Treatment of the underlying cardiovascular disorder.

Noncirrhotic Portal Fibrosis

Q. Write a short note on noncirrhotic portal fibrosis.

- Noncirrhotic portal fibrosis (NCPF) is an idiopathic disease characterized by periportal fibrosis and involvement of small and medium branches of portal vein.
- It leads to development of portal hypertension and splenomegaly without features of liver cell failure.
- Worldwide it accounts for 3–5% of all patients with portal hypertension, but in India it accounts for 15–20% of cases of portal hypertension.

Etiology

Bacterial infections, exposure to toxins (arsenic, vinyl chloride monomer, copper sulfate, methotrexate, hypervitaminosis A, 6-mercaptopurine), immunological abnormalities and hypercoagulable states may play a role.

Clinical Features

- Characterized by upper GI bleed, **massive splenomegaly** with anemia
- Preserved liver function
- **Ascites, jaundice, and hepatic encephalopathy are uncommon.**

Investigations

- *Liver function tests:* Usually normal
- *Peripheral blood:* Pancytopenia may develop due to hypersplenism.
- *Doppler ultrasound:* It shows patent splenoportal axis and hepatic veins.
- *Splenoportovenography (SPV):* It reveals massive dilatation of the portal and splenic veins, and the presence of collaterals.
- *Liver biopsy:* Lobular architecture maintained, portal fibrosis of variable degree, sclerosis and obliteration of small-sized portal vein radicals.

Treatment: Endoscopic sclerotherapy or banding to prevent variceal bleed and shunt surgery.

Differences between extrahepatic portal venous obstruction (EHPVO), NCPF, and cirrhosis are presented in **Table 6.53**.

TABLE 6.53: Differences between EHPVO, NCPF, and cirrhosis.

Features	*EHPVO*	*NCPF*	*Cirrhosis*
Median age	10 years	28 years	40 years
Ascites	Absent	Absent	+++
Encephalopathy	Nil	Nil	Present
Deranged LFT	Nil	Nil	Present
Splenomegaly	Moderate-massive	Moderate	Mild-moderate
Abdominal vein	Nil	Nil	Anterior abdominal veins +
Liver–gross	Normal	Normal	Shrunken, nodular
Liver biopsy	Normal	Portal fibrosis	Hepatic necrosis, fibrosis, regenerative nodules
Ultrasonography	Portal/splenic vein block and cavernoma	Dilated and patent portal vein	Coarse echotexture of liver. Dilated portal vein, ascites
Site of block	Extrahepatic presinusoidal	Intrahepatic presinusoidal	Intrahepatic sinusoidal and postsinusoidal

(EHPVO: Extrahepatic portal venous obstruction; LFT: Liver function test; NCPF: Noncirrhotic portal fibrosis)

Common Causes of Painful Hepatomegaly (Table 6.54)

TABLE 6.54: Common causes of painful hepatomegaly.

Hepatitis	*Amoebic liver abscess*	*Malignancies*
➢ Viral hepatitis	➢ Pyogenic liver abscess	➢ Hepatocellular carcinoma
➢ Drug-induced hepatitis	➢ Actinomycosis	➢ Secondaries
➢ Alcoholic hepatitis	➢ Congestive cardiac failure	
➢ Chronic hepatitis	➢ Acute Budd-Chiari syndrome	

Q. What are the common causes of hepatomegaly with tenderness (tender hepatomegaly)?

Causes of Pulsatile Liver (Box 6.36)

Q. Write a short note on causes of pulsatile liver.

Box 6.36: Causes of pulsatile liver.

- Tricuspid regurgitation (systolic)
- Tricuspid stenosis (diastolic)
- Aortic regurgitation

Causes of Splenomegaly (Table 6.55)

Q. Enumerate the common causes of splenomegaly.

TABLE 6.55: Classification of splenomegaly and their causes.

Mild splenomegaly (up to 5 cm)	
Acute infections	Septic shock, infective endocarditis, enteric fever, infectious hepatitis, infectious monoculeosis, brucellosis, cytomegalovirus, toxoplasmosis
Chronic infections	Tuberculosis, syphilis, brucellosis, chronic bacteremia, HIV
Parasitic infestations	Malaria, kala-azar, and schistosomiasis

Contd...

Contd...

Inflammation	Rheumatoid arthritis, sarcoidosis, SLE
Others	Congestive cardiac failure, thalassemia minor
Moderate splenomegaly (up to umbilicus) (5–8 cm)	
Neoplastic	Lymphomas, acute leukemias, chronic lymphocytic leukemia, chronic myeloid leukemia
Nonneoplastic	Cirrhosis of liver (with portal hypertension), chronic hemolytic anemia, malaria, kala-azar, sarcoidosis, infectious mononucleosis, splenic abscess, amyloidosis, hemochromatosis, polycythemia vera
Massive splenomegaly (below umbilicus) (more than 8 cm) (Fig. 6.33)	
Common causes	Chronic myeloid leukemia, myelofibrosis, kala-azar, hairy cell leukemia, tropical splenomegaly, portal hypertension (extrahepatic portal vein thrombosis), hyperreactive malarial splenomegaly
Uncommon causes	Lymphomas, Gaucher's disease, Niemann–Pick disease, thalassemia major, splenic cysts and tumors of spleen, myeloid metaplasia, hairy cell leukemia, sarcoidosis, *MAC* infection in HIV patients

(MAC: *Mycobacterium avium* complex; SLE: Systemic lupus erythematosus)

Causes of Hepatosplenomegaly (Table 6.56 and Figs. 6.34 and 6.35)

TABLE 6.56: Causes of hepatosplenomegaly.

Infections: Malaria, kala-azar, infective hepatitis, disseminated tuberculosis (TB), bacterial endocarditis, infectious mononucleosis	**Hematological disorders:** Chronic hemolytic anemia, chronic myeloid leukemia, myelofibrosis, Hodgkin and non-Hodgkin lymphoma
Congestive states: Congestive cardiac failure, constrictive pericarditis, cirrhosis of liver with portal hypertension, Budd–Chiari syndrome	**Storage disorders:** Gaucher's disease, glycogen storage disorders, and amyloidosis

HEPATIC DISORDERS OF PREGNANCY

Q. List the differential diagnosis for liver diseases during pregnancy.

Disease	***Hyperemesis gravidarum***	***Liver failure due to preeclampsia***	***Intrahepatic cholestasis***	***AFLP***	***HELLP***
Trimester	1st	>20 weeks	2nd to 3rd	2nd to 3rd	3rd to postpartum
Frequency	0.3–2%	<10%	0.1–5%	0.01%	0.2–0.6%
Clinical features	Nausea, vomiting, dehydration, weight loss, features of ketosis	Hypertension, proteinuria, headache, blurring of vision, edema of extremities	Jaundice rarely, pruritus	Abdominal pain, proteinuria, encephalopathy	Abdominal pain, vomiting, proteinuria, headache, edema of extremities
Ascites	Nil	Nil	Nil	May be present	Nil

Contd...

Contd...

Disease	***Hyperemesis gravidarum***	***Liver failure due to preeclampsia***	***Intrahepatic cholestasis***	***AFLP***	***HELLP***
Platelet count	No change	Decreased	No change	Decreased	Decreased
Hemolysis	No change	Increased	No change	No change	May be increased
Bilirubin and bile acids	Bilirubin remains low. No change in bile acids	Bilirubin remains low. No change in bile acids	Bile acids may be increased 50–100 times	Mildly increased bilirubin; no change in bile acids	Bilirubin remains low. No change in bile acids
AST/ALT	1–2 times normal	1–100 times normal	1–5 times normal	5–10 times normal	1–100 times normal
LDH	No change	Mildly increased	No change	Mildly increased	Usually above 600 IU/L
ALP	No change	Mildly increased	Increased	Increased	Increased
Uric acid	No change	Increased	No change	Highly increased	Increased
Treatment	Supportive therapy, antiemetics, vitamin replacement, admission if dehydration is severe	Good control of blood pressures, careful monitoring for progression into eclampsia	Ursodeoxycholic acid may be administered. Delivery preferably at 36–37 weeks	Delivery to be done early preferably at 34–36 weeks	Delivery to be done early. May need to go as early as 24–34 weeks as long as antenatal corticosteroids are given
Complications	Resolves spontaneously by 18 weeks	Maternal and perinatal mortality	Late IUDs	Liver rupture, necrosis, maternal and perinatal mortality	Maternal and perinatal mortality

(AFLP: Acute fatty liver of pregnancy; ALT: Alanine aminotransferase; ALP: Alkaline phosphatase; AST: Aspartate aminotransferase; HELLP: Hemolysis, elevated liver enzyme levels, and low platelet levels; LDH: Lactate dehydrogenase)

Causes of Hepatosplenomegaly with Lymphadenopathy

See **Box 6.37.**

Box 6.37: Causes of hepatosplenomegaly with lymphadenopathy.

- Lymphomas
- Infectious mononucleosis
- HIV
- Sarcoidosis
- Lymphocytic leukemia
- Disseminated tuberculosis
- Disseminated histoplasmosis

GALLBLADDER

Cholecystitis

Q. IM5.8 Describe and discuss the pathophysiology, clinical evolution and complications cholecystitis.

- **Definition:** It refers to the inflammation of the gallbladder.
- It is of 2 types—acute and chronic.
- Acute cholecystitis refers to a syndrome of right upper quadrant pain, fever, and leukocytosis associated with gallbladder inflammation
- Acute cholecystitis is again divided into 2 types:
    i. Acute calculous cholecystitis—which is the most common cause
    ii. Acute acalculous cholecystitis—5–10% of cases.

Acute Calculous Cholecystitis

- It is acute necroinflammatory disease of the gallbladder with multifactorial pathogenesis.
- Accounts to 10% of cases of Acute cholecystitis and is associated with high mortality and morbidity rates.

Causes

- Common in ICU patients—in critically-ill patients.
- It is due to bile stasis and ischemia.
- Common in AIDS, elderly males, diabetics, patients who have undergone major nonbiliary surgery.
- Patients on TPN, atherosclerotics.

Pathology is edema and necrosis of the gallbladder wall with features of acute inflammation.

- Clinical presentation is usually acute.
- Gangrene, perforation, empyema are common

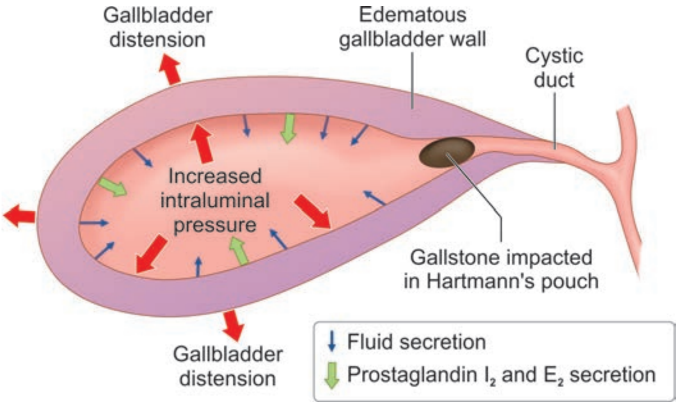
Investigations: Routine lab investigations—mainly TLC and LFT, USG abdomen.

- Isotope study (HIDA)
- Role of CT appears similar to USG

Treatment

- Percutaneous US-guided/CT-guided or open cholecystostomy initially.
- Cholecystectomy is the treatment of choice later.

- **Chronic cholecystitis**—it is due to recurrent attacks of acute cholecystitis leading to fibrosis and thickening of gallbladder and extensive chronic inflammation with minimal symptoms.
- **Bacterial causes**—
  - *E. coli*—most common
  - *Klebsiella, Pseudomonas, Proteus*
  - *Streptococcus faecalis*
  - *Salmonella*
  - *Clostridium welchii*



Gallbladder distension
Edematous gallbladder wall
Cystic duct
Increased intraluminal pressure
Gallstone impacted in Hartmann's pouch
Gallbladder distension
↓ Fluid secretion
↓ Prostaglandin I₂ and E₂ secretion

FIG. 6.36: Features of acute/chronic cholecystitis.

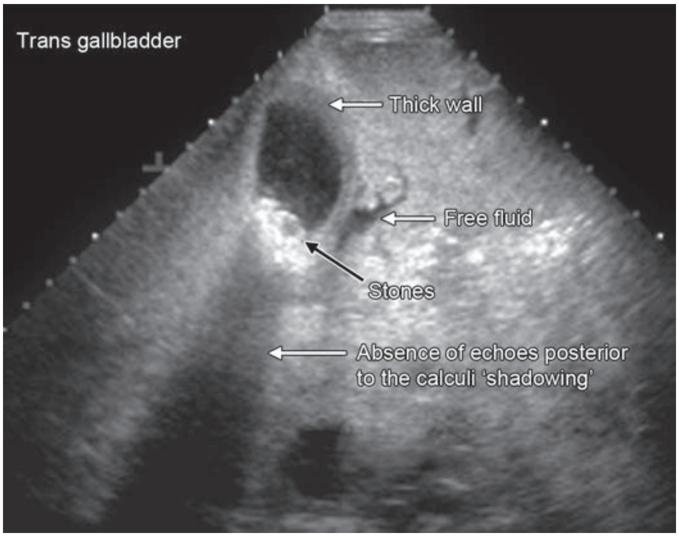
Pathogenesis and pathology: Gallbladder will be distended with edematous friable wall and the wall contains dilated vessels. Mucosa shows ulceration and necrosis. Lumen contains infected fluid/infected bile or frank pus. *Histology* shows features of acute inflammation with neutrophils, edema, and areas of necrosis and cell death **(Fig. 6.36)**.

Clinical features:

- Sudden onset of pain in the right hypochondrium, with tenderness, guarding, and rigidity.
- Area of hyperesthesia between 9th and 11th ribs posteriorly on the right side (Boas's sign).
- Jaundice may be present.
- Fever, nausea, vomiting, anorexia
- Palpable tender mass in right hypochondrium
- Positive Murphy's sign—while palpating the gallbladder, patient is asked to take deep inspiration and due to descent of inflamed gallbladder on deep inspiration, patient experiences discomfort and holds the breath (this sign is more sensitive than specific).

Laboratory investigations:

- Ultrasound abdomen **(Fig. 6.37)**—very useful, reveals presence or absence of gallstones; and thickening of gallbladder wall. Sonographic Murphy's sign may be positive.
- Contrast enhanced USG if plain USG is negative.
- Plain X-ray abdomen—10% of gallstones are radio-opaque, gas is seen in emphysematous gallbladder.
- Blood investigations—total count may show neutrophilia, LFT—obstructive jaundice pattern—signifies cholangitis
- HIDA/PIPIDA radioisotope study/cholescintigraphy—very useful. Non-visualization of gallbladder post on 30-min post-morphine is diagnostic. Sensitivity and specificity are 90—97% and 71—90%, respectively **(Fig. 6.38)**.
- CT scan is useful in identifying the perforation, impacted stone, gallbladder wall thickness and edema



Trans gallbladder
Thick wall

FIG. 6.38: HIDA scan showing acute cholecystitis.
(HIDA: Hepatobiliary iminodiacetic acid; GB: Gallbladder; CBD: Common bile duct)

- The following procedures are preferred when there is acute cholecystitis with obstructive jaundice or in choledocholethiasis picture.
    - MRCP
    - Endoscopic ultrasound
    - ERCP

Differential diagnosis—should be differentiated from other causes of acute pain abdomen.

- Acute pancreatitis
- Acute appendicitis
- Duodenal ulcer perforation
- Acute pyelonephritis
- Ruptured ectopic pregnancy
- Myocardial infarction

Complications of acute cholecystitis:

- Perforation—which usually occurs in the fundus or in the neck
- Cholecystoduodenal, cholecystointestinal or cholecystobiliary fistula
- Mirrrizi's syndrome
- Peritonitis
- Pericholecystic abscess
- Cholangitis
- Septicemia
- Empyema gallbladder
- Gangrenous gallbladder

Treatment

- Patient is advised hospitalization
- First step is conservative treatment—
    - Nasogastric aspiration
    - IV fluids
    - Analgesics and antispasmodics
    - Broad-spectrum antibiotics
    - Observation
    - Follow-up USG scan
- 3-6 weeks later elective interval cholecystectomy will be done via open or laparoscopic method
- Emergency cholecystectomy is required in—
    - Emphysematous cholecystitis
    - Progressing or persisting symptoms

CHOLELITHIASIS

Q. IM5.8 Describe and discuss the pathophysiology, clinical evolution and complications of cholelithiasis.

It is gallstone disease.

There are 3 different types of gallstones mainly **(Fig. 6.39)**

a. Cholesterol stones—often solitary.

b. Mixed stones are 90% common. It contains cholesterol, calcium salts of phosphate carbonate, palmitate, proteins, and are multiple faceted.

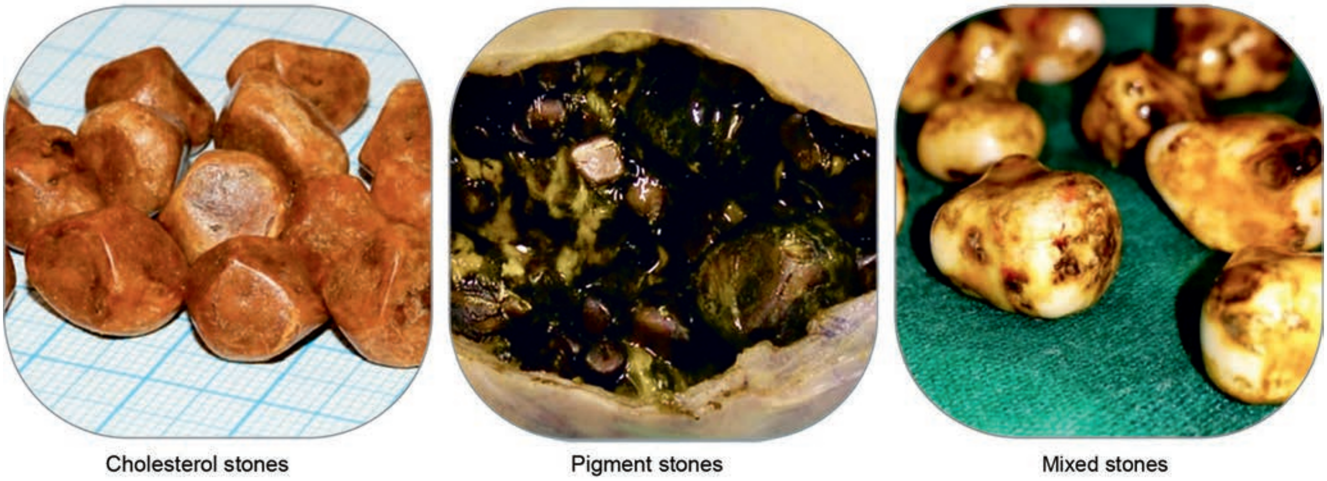

FIG. 6.39: Types of gallstones.

c. Pigment stones are small, black or greenish black, multiple.
    - Common in "Fat, Fertile, Forty, Flatulent, Female".
    - Common in western countries and in north India.

Gallstone disease is of 2 types:

1. Uncomplicated gallstone disease
2. Complicated gallstone disease

Lysolecithin
saturated FA
UCB
Free bile acids
Mucin gel
B

FIGS. 6.41A AND B: Pathogenesis of gallstones.
(ROS: Reactive oxygen species; UCB: Unconjugated bilirubin)

Clinical Features

Most of the individuals can be asymptomatic and incidentally detected upon abdominal imaging.
It is rare to have complications without having biliary colic for the incidental gallstones.

Symptomatic gallstone disease

- **Biliary colic:** Contraction of the gallbladder due to the hormones and neuronal response, forcing the stone against the gallbladder outlet, leading to increase in pressure. Increase in pressure causes pain and when gallbladder relaxes, the stone often falls back from cystic duct and pain subsides.
  - It is an intense, dull discomfort, located in the right upper quadrant, epigastrium or substernal area, occasionally radiating to the back.
  - Patient describes it typically as having pain after eating a fatty meal.
  - Pain is mainly nocturnal and not relieved by squatting or any bowel movements. The entire attack usually lasts for 6 hours.

Atypical symptoms include:

- Belching
- Bloating/abdominal distension
- Nausea, vomiting, anorexia
- Regurgitation/retrosternal or epigastric burning
- Early satiety
- Non-specific abdominal pain.

Complications of gallstone disease

- Silent gallbladder
- Acute cholecystitis
- Chronic cholecystitis
- Biliary colic with periodicity
- Cholecystoduodenal fistula
- Gallstone ileus—passage of a gallstone, usually larger than 2.5 cm, through a cholecystoenteric fistula may lead to the development of mechanical bowel obstruction (usually in the narrowest part of the terminal ileum which is approximately two feet proximal to the ileocecal valve)
- Empyema of the gallbladder
- Mucocele of gallbladder
- Limey gallbladder
- Carcinoma gallbladder
- Secondary CBD stone (10%)
- Mirizzi syndrome: It is a rare condition caused by the obstruction of the common bile duct or common hepatic duct by external compression from multiple impacted gallstones or a single large, impacted gallstone in Hartman's pouch
- Cholangitis
- pancreatitis

Investigations

- Lab investigations—include TLC, LFT mainly to check for sepsis and obstructive jaundice pattern
- USG abdomen to check for the radiolucent gallstones
- X-ray abdomen to check for the radio-opaque gallstones
- CT scan abdomen to rule out presence of CBD stones

Treatment

- Laparoscopic cholecystectomy ideal.
  - Open cholecystectomy is done through right subcostal Kocher's incision.
  - Open approach is used—in suspected CBD stones, Mirizzi syndrome, suspected carcinoma gallbladder.

7

CHAPTER

Pancreas

PANCREATITIS

Acute Pancreatitis

Q Discuss the etiology, clinical features, investigations, diagnosis, complications and management of acute pancreatitis.

Definition

Acute pancreatitis is best defined clinically by a patient presenting with two of the three criteria listed in **Box 7.1**.

Box 7.1: Criteria for diagnosis of acute pancreatitis.

- **Symptoms:** Epigastric pain, consistent with the disease.
- **Laboratory findings:** Serum amylase or lipase three times greater than the upper limit of normal.
- **Radiologic imaging:** Findings consistent with the diagnosis, by either computed tomography (CT) or magnetic resonance imaging (MRI).

Classification of Acute Pancreatitis

Atlanta classification of acute pancreatitis

- **Interstitial edematous acute pancreatitis:** Characterized by acute inflammation of the pancreatic parenchyma and peripancreatic tissues, but without tissue necrosis.
- **Necrotizing acute pancreatitis:** Characterized by inflammation associated with pancreatic parenchymal necrosis and/or peripancreatic necrosis.

Classification of acute pancreatitis according to the severity

- **Mild acute pancreatitis:** Not associated with organ failure and local or systemic complications.
- **Moderately severe acute pancreatitis:** No organ failure or transient organ failure (<48 hours) and/or local complications.
- **Severe acute pancreatitis:** Persistent organ failure (>48 hours) that may involve one or multiple organs.

Etiology (Table 7.1) (Box 7.2)

Q. Describe etiology of acute pancreatitis.

TABLE 7.1: Causes of acute pancreatitis.

Obstructive causes	*Toxins*
➢ Gallstones (40–70%) ➢ *Obstruction of the pancreatic duct system:* Ampullary or pancreatic tumors ➢ *Biliary sludge and microlithiasis* ➢ *Parasites: Ascaris lumbricoides* and *Clonorchis sinensis* organisms ➢ *Developmental anomalies:* Pancreas divisum, choledochocele, annular pancreas	➢ Ethyl alcohol (25–35%) ➢ Methyl alcohol ➢ Scorpion venom ➢ Snake venom ➢ Organophosphates ➢ Insecticides ➢ Smoking
Drugs	***Metabolic causes***
➢ *Definite association:* Azathioprine, 6-mercaptopurine, valproic acid, estrogens, corticosteroids, didanosine, tetracycline ➢ *Probable association:* Thiazides, ethacrynic acid, phenformin, procainamide, chlorthalidone, L-asparaginase, pentamidine	➢ Hypertriglyceridemia (1–14%) ➢ Hyperparathyroidism ➢ Hyperlipoproteinemia ➢ Hypercalcemia ➢ Renal failure ➢ Postrenal transplantation

Contd...

Contd...

Trauma	***Infectious***
➢ *Accidental*: Blunt trauma to the abdomen ➢ *Iatrogenic injury:* – Postoperative, – Postendoscopic retrograde cholangiopancreatography (3–5%) – Postendoscopic sphincterotomy – Post-sphincter of Oddi manometry	➢ *Viral:* Mumps, rubella, viral hepatitis, coxsackie virus B, echovirus, cytomegalovirus, human immunodeficiency virus (HIV) ➢ *Bacterial:* Mycoplasma, *Campylobacter jejuni*, tuberculosis, *Legionella* species, Leptospirosis ➢ *Fungi: Aspergillus* ➢ *Parasites: Clonorchis sinensis, Toxoplasma, Cryptosporidium, Ascaris, Echinococcus granulosus, Fasciola hepatica*
Vascular	***Idiopathic***
➢ *Ischemia:* Hypoperfusion (e.g., postcardiac surgery) or atherosclerotic emboli ➢ *Vasculitis*: Systemic lupus erythematosus, polyarteritis nodosa, malignant hypertension	*Note:* Approximately 15 to 25 percent of patients with acute pancreatitis are idiopathic
Miscellaneous	***Genetic***
➢ Penetrating peptic ulcer ➢ Pregnancy associated Reye syndrome ➢ Autoimmune	➢ Mutations in the pancreatic trypsin inhibitor (*SPINK1*) gene in the cystic fibrosis transmembrane regulator (CFTR) ➢ Gain-of-function mutations in the *PRSS1* gene

Pathogenesis (Fig. 7.1)

Autodigestion of the pancreatic substance is a currently accepted pathogenic theory of acute pancreatitis. According to this theory, acute pancreatitis develops as a consequence of premature and exaggerated activation of proteolytic enzymes within the pancreas itself (e.g., trypsinogen, chymotrypsinogen, proelastase, and lipolytic enzymes such as phospholipase A_2).

Activation of pancreatic enzymes

Activation of trypsin: One of the proenzyme is trypsinogen, which is **prematurely activated to trypsin.** It is an important triggering event. Actions of trypsin are:

- ***Activates other proenzymes:*** Trypsin converts many proenzymes into active forms (such as proelastase and prophospholipase). Activated enzymes elastase (from proelastase) and phospholipase (prophospholipase) can damage the elastic fibers of blood vessels and degrade fat cells.

Box 7.2: Mnemonic for causes of pancreatitis.

Proenzymes
Activated enzymes
Proteolysis by proteases
Fat necrosis by lipase, phospholipase
Hemorrhage by elastase acting on blood vessel wall
Acute pancreatitis

FIG. 7.1: Pathogenesis of acute pancreatitis.

- ***Activation of kinin, clotting and complement system:*** Trypsin acts on kinin system and converts prekallikrein to its activated form kallikrein. This in turn can activate Hageman factor (factor XII), the clotting and complement systems.

The severity of acute pancreatitis depends on the balance of two opposite sets of forces, namely the activity of released proteolytic enzymes and antiproteolytic factors. The latter consists of an intracellular pancreatic trypsin inhibitor protein and circulating β2-macroglobulin, α1-antitrypsin and C1-esterase inhibitors.

Clinical Features

Q. Write short note on signs and symptoms of acute pancreatitis.

Symptoms

- **Abdominal pain:** It is the cardinal and major symptom of acute pancreatitis. Its characteristics are:
  - **Location:** Upper abdominal pain usually located in the **epigastric and periumbilical region** more on the left or right side, depending on the portion of the pancreas is involved.
  - **Onset: Sudden** onset and gradually increases in severity.
  - **Nature: Constant, steady, intense** (over 15–60 minutes)/dull and boring.
    - Pain is relieved by sitting or leaning forward (Mohammedan prayer sign) due to shifting forward of abdominal contents and taking pressure off from inflamed pancreas.
    - When the retroperitoneum is involved, pain often **radiates to the upper back** as well as to the chest, flanks, and lower abdomen.
    - 5–10% of patients with acute severe pancreatitis may have *painless disease* and have *unexplained hypotension.*
- **Other symptoms:** These include anorexia, nausea, and vomiting.

Acute pancreatitis may present as acute abdomen as a medical emergency.

Signs

- **Early stages**
  - Distressed and anxious patient.
  - **Marked epigastric tenderness** and **abdominal distension** (due to gastric and intestinal hypomotility). In the **early stages**, rebound **tenderness and guarding are absent** because the inflammation is mainly in the retroperitoneal region.
  - Tachypnea due to ARDS, atelectasis and pleural effusion.
  - In patients with gallstones **jaundice** may develop due to compression of the intrapancreatic portion of the common bile duct caused by edema of the head of the pancreas.
- **Severe disease**
  - **Low grade fever, tachycardia**, and **hypotension** are common.
  - **Shock with oliguria** may develop due to:
    - Hypovolemia secondary to exudation of blood and plasma into the retroperitoneal space.
    - Vasodilation and increased vascular permeability produced due to increased formation and release of kinin peptides.
    - Systemic effects of proteolytic and lipolytic enzymes released from the pancreas into the circulation.
  - **Abdominal examination** may show tenderness with guarding as well as diminished or absent bowel sounds (when paralytic ileus develops).
  - **Respiratory system:** Lungs findings include basal rales, atelectasis, and pleural effusion (68% left sided effusion).
  - **Skin:** Erythematous skin nodules due to focal subcutaneous fat necrosis may be seen.
  - **Purtscher retinopathy:** Ischemic injury to retina may be visible on fundus examination.
  - **Cutaneous ecchymoses:**
    - **Cullen's sign:** Faint bluish discoloration (bruising) around the umbilicus **(Fig. 7.2)** due to hemoperitoneum. It may be also found in association with ruptured ectopic

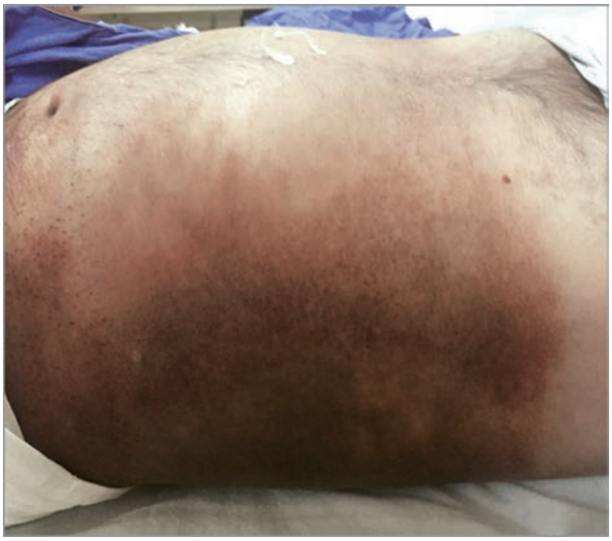

FIG. 7.2: Ecchymotic discoloration in the periumbilical region (Cullen's sign) or along the flank (Grey Turner's sign).

pregnancy, ruptured aortic aneurysm, ruptured spleen and hepatocellular carcinoma, blunt abdominal trauma and spontaneous bleeding secondary to coagulopathy.

- **Grey Turner's sign:** Blue-red-purple or green-brown discoloration of the flanks **(Fig. 7.2)** due to tissue catabolism of hemoglobin.
- **Fox's sign:** Bluish discoloration over the inguinal ligament.

Laboratory Investigations

Q. Write short note on diagnosis and treatment of acute pancreatitis.

Q. BI11.17 Explain the basis and rationale of biochemical tests done in pancreatitis.

Blood

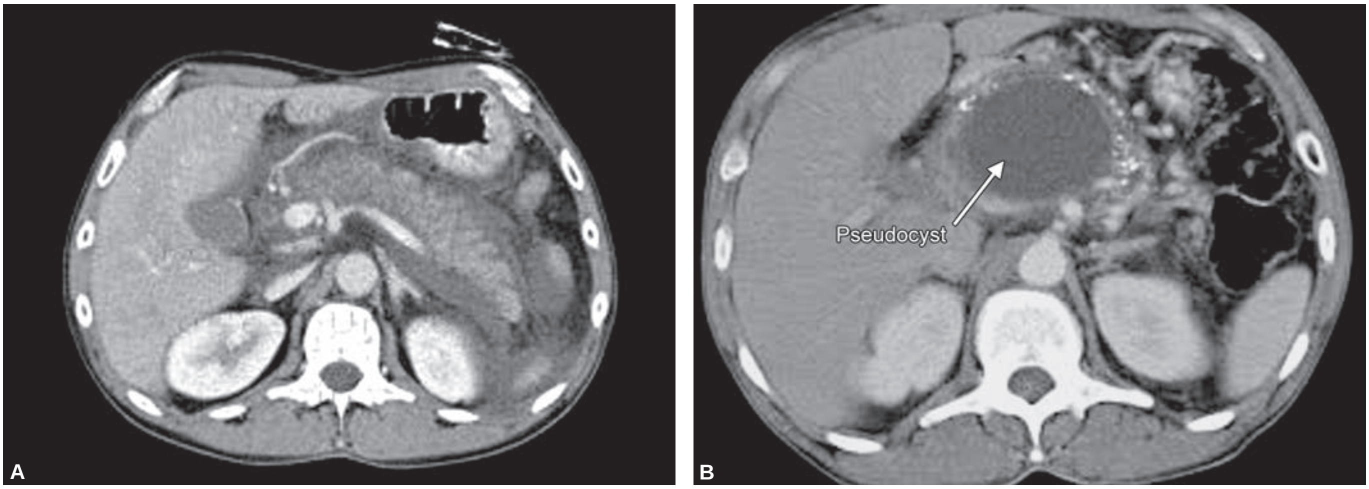
The diagnosis of acute pancreatitis is usually established by the finding of **raised level of serum amylase and lipase** and ultrasound or CT evidence of pancreatic swelling.

1. ***Serum amylase:***
    - Levels markedly (three times the upper limit of normal) raised within 6–12 hours and then decline to normal within 3–5 days.
    - Persistently elevated serum amylase levels indicate development of complications such as pancreatic abscess or pseudocyst formation.
    - Amylase levels may be spuriously normal in 20% patients with alcoholic pancreatitis and 50% patients with hypertriglyceridemia.
    - Peritoneal amylase is massively raised in pancreatic ascites.
    - *Serum amylase concentrations are also elevated in other conditions like perforated bowel, salivary gland obstruction/infection, ruptured ectopic pregnancy, renal failure, mesenteric infarction macroamylasemia, etc.*
2. ***Urinary amylase:*** Levels may be diagnostic because they remain elevated over a longer period of time.
3. ***Serum lipase:***
    - Preferable to amylase for diagnosis as it remains elevated for a longer period of time (8–14 days) than levels of serum amylase. It has **greater diagnostic accuracy** and is a more useful indicator of acute pancreatitis.
    - Rises within 4–8 hours of the onset of symptoms, peaks at 24 hours.
    - Marked elevation of lipase in pleural or peritoneal fluid (> 5000 IU/dL) suggests acute pancreatitis.
4. ***C-reactive protein level:*** It is useful in assessing severity and prognosis of acute pancreatitis.
5. ***Other blood investigations:***
    - **Low Hb:** Indicates prolonged hematemesis/melena, internal hemorrhage.
    - **Leukocytosis:** Moderate to severe acute pancreatitis usually show leukocytosis.
    - **Low platelets:** Disseminated intravascular coagulation (DIC)
    - **Hyperglycemia and glycosuria:** It occurs in 10% of cases. Possibly due to hyperglucagonemia, associated with relative hypoinsulinemia.
    - **Hypocalcemia:** It is due to precipitation of calcium soaps in necrotic fat. Persistent hypocalcemia is a poor prognostic sign.
    - **Other baseline investigations:** These include urea and electrolytes, liver biochemistry [raised bilirubin, aspartate transaminase (AST), alanine transaminase (ALT), lactate dehydrogenase (LDH), alkaline phosphatase (ALP), gamma-glutamyl transpeptidase (GGTP)-gallstone pancreatitis], LDH, triglycerides, and arterial blood gases.

Radiology

The enlarged inflamed pancreas may be directly visualized by radiography.

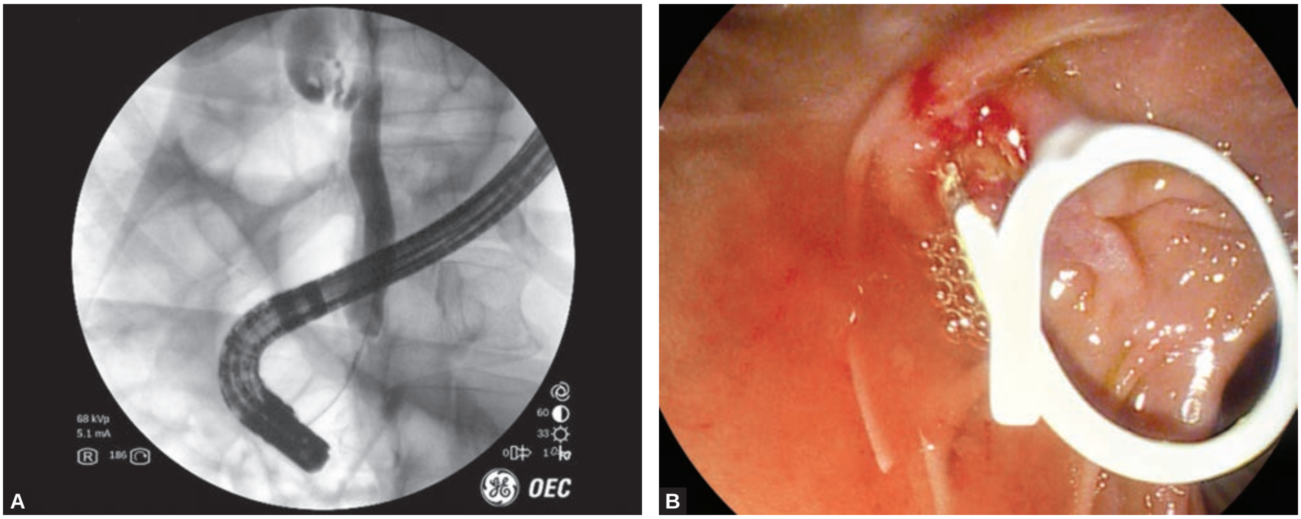
- ***Plain X-ray (X-ray abdomen and chest):*** Useful for excluding other causes of acute abdominal pain (e.g., gastroduodenal perforation or obstruction). A supine abdominal X-ray may reveal gallstones or pancreatic calcification. Nonspecific signs like 'colon cut-off sign', 'sentinel loop sign' can be seen.
- ***Abdominal ultrasound scan:*** Used as a screening test to evaluate gallbladder and biliary tree (to identify gallstones, biliary obstruction or pseudocyst formation). It may show pancreatic swelling, necrosis and peripancreatic fluid collections. However, the pancreas may not be visualized because of gas-filled loops of bowel.
- ***CT scan of abdomen:*** May show swollen pancreas (phlegmon), pseudocyst **(Figs. 7.3A and B)** or pancreatic abscess. Helpful in **assessing the severity,** the risk of morbidity and mortality and the complications of acute pancreatitis.
    - ***Contrast-enhanced CT scanning:*** Should be performed after 72 hours of onset of symptoms to know the extent of pancreatic necrosis. Necrotizing pancreatitis shows decreased pancreatic enhancement on CT, following intravenous injection of contrast material.



FIGS. 7.3A AND B: CT image showing: **A.** Exudative pancreatitis; **B.** Pseudocyst.

It can detect complications such as fluid collections, abscess formation, pseudocyst and involvement of the colon, blood vessels and other adjacent structures by the inflammatory process. The presence of gas within necrotic material suggests infection and possible abscess formation.

- ***MRI abdomen and magnetic resonance cholangiopancreatography (MRCP):*** Its uses are:
  - For assessing the degree of pancreatic damage/necrosis.
  - To identify gallstones within the biliary tree.
  - To differentiate between fluid and solid inflammatory masses.
- ***Endoscopic retrograde cholangiopancreatography (ERCP):*** Used for removing bile duct stones in few selected cases of gallstone-related pancreatitis and for sphincterotomy/stent placement **(Figs. 7.4A and B)**.



FIGS. 7.4 AND B: ERCP and stent placement.

Determining the Severity of Acute Pancreatitis

- **Course of acute pancreatitis:** Majority of cases of acute pancreatitis are mild and run a short, self-limiting course. About 25% develop a more complicated course and in about 10% this may be life-threatening.
- The **best scoring system** available is: **Ranson scoring system (Table 7.2)**.
- The **modified Glasgow (Box 7.3) or the Imrie criteria** consists of 8 parameters and requires a 48-hour period of observation and scores 3 or more it indicates severe pancreatitis.
- **Acute physiology and chronic health evaluation (APACHE) II score:** It is based on common physiological and laboratory values, adjusted for age and the presence or absence of a number of other chronic health problems (>8 predicts severe disease).

TABLE 7.2: Ranson criteria for assessing severity of acute pancreatitis.

Factors	***Alcoholic pancreatitis***	***Gallstone pancreatitis***
1. On admission		
Age	>55 years	>70 years
WBC count	>16,000/cumm	>18,000/cumm
Blood glucose	>200 mg/dL	>220 mg/dL
Serum lactate dehydrogenase (LDH)	>350 IU/L	>400 IU/L
Serum aspartate aminotransferase (AST)	>250 IU/L	>250 IU/L
2. Within 48 hours		
Hematocrit decreases	>10%	—
Increase of blood urea nitrogen (BUN)	>5 mg/dL	>2 mg/dL
Serum calcium	<8 mg/dL	<8 mg/dL
PaO$_2$	60 mmHg	—
Base deficit	>4 mEq/L	>5 mEq/L
Fluid deficit	>6 L	>4 L
Number of criteria and approximate mortality (%): 0 to 2 = 0%; 3 to 4 = 15%; 5 to 6 = 50%; >6 = 100%.		

TABLE 7.3: Computed tomography (CT) grading system of Balthazar and CT severity index (CTSI).

Balthazar grades			
Grade A		Normal pancreas consistent with mild pancreatitis	
Grade B		Focal or diffuse enlargement of the gland, including contour irregularities and inhomogeneous attenuation but without peripancreatic inflammation	
Grade C		Grade B plus peripancreatic inflammation	
Grade D		Grade C plus associated single fluid collection	
Grade E		Grade C plus two or more peripancreatic fluid collections or gas in the pancreas or retroperitoneum	
CTSI = Balthazar grade score plus necrosis score*			
Balthazar grade score:		Necrosis score:	
A	= 0	Absence of necrosis	0
B	= 1	Necrosis of up to 33% of pancreas	2
C	= 2	Necrosis of 33% to 50%	4
D	= 3	Necrosis of >50%	6
E	= 4		

*Score = morbidity [%]/mortality [%]: 0 to 3 = 8%/3%; 4 to 6 = 35%/6%; 7 to 10 = 92%/17%.

Box 7.3: Modified Glasgow criteria.

P—PaO$_2$ <8 kPa
A—Age >55-year-old
N—Neutrophilia: WBC >15 × 10^9/L
C—Calcium <2 mmol/L
R—Renal function, urea >16 mmol/L
E—Enzymes: LDH >600 IU/L; AST >200 IU/L
A—Albumin <32 g/L (serum)
S—Sugar: Blood glucose >10 mmol/L

- **Bedside index for severity in acute pancreatitis (BISAP),** also uses the first letter of each parameter for 1 point. *The BISAP score provides a single point for 5 parameters: blood urea nitrogen (BUN) greater than 25 mg/dL, impaired mental status, systemic inflammatory response syndrome, age greater than 60, and/or the presence of a pleural effusion, for a possible total of 5 points.* A BISAP score greater than 3 is associated with a seven- to twelve-fold increase in developing organ failure.
- **Computed tomography (CT) grading system of Balthazar and CT severity index (CTSI) is presented in Table 7.3 (added score >5 indicates severe pancreatitis).**

Apart from the above scoring systems, individual laboratory tests have been suggested to establish severity.

- These include methemalbumin, alpha-2 macroglobulin, alpha-1 antitrypsin, C3 and C4 levels, phospholipase A2, C-reactive protein, trypsinogen-activated peptide (TAP) and granulocytic elastase.

Differential Diagnosis of Acute Pancreatitis

See **Table 7.4.**

TABLE 7.4: Differential diagnosis of acute pancreatitis.

- Perforation: Peptic ulcer/intestinal
- Acute cholecystitis
- Acute appendicitis
- Bowel ischemia
- Acute myocardial infarction
- Pneumonia
- Abdominal aortic dissection
- Diabetic ketoacidosis
- Renal colic
- Acute hepatitis

Complications of Acute Pancreatitis

Q. List the complications of acute pancreatitis.

Local (Pancreatic) Complications

- **Acute peripancreatic fluid collections (APFC)** do not have a well-defined wall, usually remain asymptomatic.
- **Pancreatic pseudocyst:** It represents a localized peripancreatic collection of pancreatic juice and debris usually developing in the lesser sac following inflammatory rupture of the pancreatic duct. It may be palpable in the upper abdomen four to six weeks after onset of symptoms. Small pseudocysts are common and resolve as the pancreatitis recovers, but those larger than 6 cm can persist causing abdominal pain and may compress or erode surrounding structures.
- **Pancreatic necrosis *(sterile or infected):*** Necrosis may result in an acute necrotic collection (ANC) that contains a variable amount of fluid and necrosis or walled-off necrosis (WON), which consists of a mature, encapsulated collection.
- **Pancreatic abscess:** Localized collection of pus close to the pancreas and containing little or no pancreatic necrotic tissue.
- **Pancreatic ascites:** May develop due to leakage of fluid from a disrupted pancreatic duct into the peritoneal cavity. Systemic complications are listed in **Table 7.5.**

TABLE 7.5: Complications of acute pancreatitis.

Local	***Systemic***

➢ **Acute peripancreatic fluid collections (APFC)** do not have a well-defined wall
➢ **Pseudocyst:** Encapsulated collection of fluid with a well-defined inflammatory wall usually outside the pancreas with minimal or no necrosis
➢ **Necrosis:** Acute necrotic collection **(ANC)** that contains a variable amount of fluid and necrosis but lacks a definable wall walled-off necrosis **(WON),** which consists of a mature, encapsulated collection of pancreatic and/or peripancreatic necrosis that has developed a well-defined inflammatory wall.
➢ **Abscess**
➢ **Pancreatic ascites**
  – Disruption of main pancreatic duct
  – Leaking pseudocyst
➢ Involvement of contiguous organs by necrotizing pancreatitis
➢ Massive intraperitoneal hemorrhage
➢ Thrombosis of blood vessels (splenic vein, portal vein)
➢ Pseudoaneurysm
➢ Bowel infarction
➢ Obstructive jaundice
➢ Abdominal compartment syndrome
	➢ Systemic inflammatory response syndrome **(SIRS)** due to increased vascular permeability caused by release of cytokine, platelet aggregating factor and kinin
	➢ **Respiratory complications:** Pleural effusion, hypoxia—adult respiratory distress syndrome (ARDS) due to microthrombi in pulmonary vessels, pneumonia
	➢ **Cardiovascular:** Hypotension and shock, hypovolemia
	➢ **Gastrointestinal complications: Upper gastrointestinal bleeding** due to gastric or duodenal erosions and paralytic ileus
	➢ **Hepatobiliary complications:** Jaundice, common bile duct obstruction (obstructive jaundice), splenic or portal vein thrombosis, variceal hemorrhage
	➢ **Renal:** Oliguria, azotemia renal artery and/or renal vein thrombosis, acute tubular necrosis
	➢ **Metabolic:** Hyperglycemia (due to disruption of islets of Langerhans with altered insulin/glucagon release), hypocalcemia—due to sequestration of calcium in fat necrosis
	➢ **Hematological complication:** Disseminated intravascular coagulation (DIC), increased factor VII or fibrinogen
	➢ Fat necrosis (subcutaneous nodules), polyarthritis
	➢ Retinopathy (Purtscher's retinopathy): Sudden blindness
	➢ **Central nervous system:** Psychosis, encephalopathy and coma

Q. Write short note on treatment of acute pancreatitis.

Management/Treatment

Steps involved

General supportive care

In about 85–90% of patients, acute pancreatitis is self-limited and subsides spontaneously. The initial management of acute pancreatitis is similar, irrespective of the cause.

- **Intravenous (IV) fluids:** 5 to 10 mL/kg per hour of isotonic crystalloid solution to maintain normal intravascular volume. There may be large amount of fluid loss during early phase of acute pancreatitis. Recent studies (WATERFALL trial) have suggested that moderate fluid resuscitation is superior to aggressive fluid resuscitation in acute pancreatitis.
- **Feeding:**
  - *Nil orally* initially **only in** severe pancreatitis.
  - In the absence of ileus, nausea or vomiting, oral feeding can be initiated early (within 24 hours) as tolerated.
  - Total **parenteral nutrition** may be associated with a high-risk of infection.
  - Nasogastric/nasojejunal administration of feed is possible in most of the patients followed by gradual oral intake.
- **Analgesia for pain:** Tramadol or other opiates (hydroxymorphine, fentanyl, meperidine) are the drugs for pain control. Morphine and diamorphine are avoided, because they may exacerbate pancreatic ductular hypertension by causing contraction of sphincter of Oddi.
- **Nasogastric suction/aspiration:** Indications include (1) continuation of pain, (2) presence of protracted vomiting or (3) obstruction observed on plain X-ray abdomen. It prevents abdominal distension and vomiting and the risk of aspiration pneumonia.
- **Prophylactic antibiotics: Prophylactic antibiotics are not recommended in patients with acute pancreatitis.** Carbapenems (imipenem or meropenem) or ceftazidime/cefuroxime are used only for infected pancreatic necrosis.
- **Other drugs:** Proton-pump inhibitors, glucagon, octreotide, pentoxifylline and aprotinin (protease inhibitor).
- **Anticoagulation** with a low molecular weight heparin for prevention of deep vein thrombosis (DVT).
- Management of acute pancreatitis **(Flowchart 7.1).**
- **Indications for surgery (Box 7.4).**
- **Endoscopic retrograde cholangiopancreatography (ERCP)** is indicated within first 36–48 hours in severe pancreatitis associated with gallstone obstruction (particularly when complicated by cholangitis or jaundice).
- Small percentage patients develop multiorgan failure (reflecting the extent of pancreatic necrosis) and all **severe cases** should be managed in a **high-dependency or intensive care unit.**
- Detection and treatment of complications
- Treatment of the underlying cause (e.g., gallstones, hypercalcemia, hypertriglyceridemia).

Box 7.4: Indications for surgery in acute pancreatitis.

- Infected pancreatic necrosis (pancreatic abscess).
- **Complications:** Most patients with complications such as acute peripancreatic fluid collections and/or pseudocysts do not require surgical interventions unless they become infected or cause compression of other organs.
- **Cholecystectomy**: It should be carried out in gallstone related pancreatitis as soon as feasible (within 2 weeks after the resolution of acute episode). This will prevent potentially fatal/recurrent episode of pancreatitis.

Chronic Pancreatitis

Q. Write short essay/note on chronic pancreatitis.

Chronic pancreatitis is defined as **chronic inflammation of the pancreas** presenting as recurrent pain, characterized by the presence of **inflammation, fibrosis, and loss of acinar and islet cells.** The pancreas shows **irreversible damage to the exocrine pancreas in the form of fibrosis causing exocrine deficiency** (malabsorption). In the **late stages**, there may be destruction of endocrine parenchyma producing endocrine deficiency (**diabetes mellitus**).

Etiology (Table 7.6)

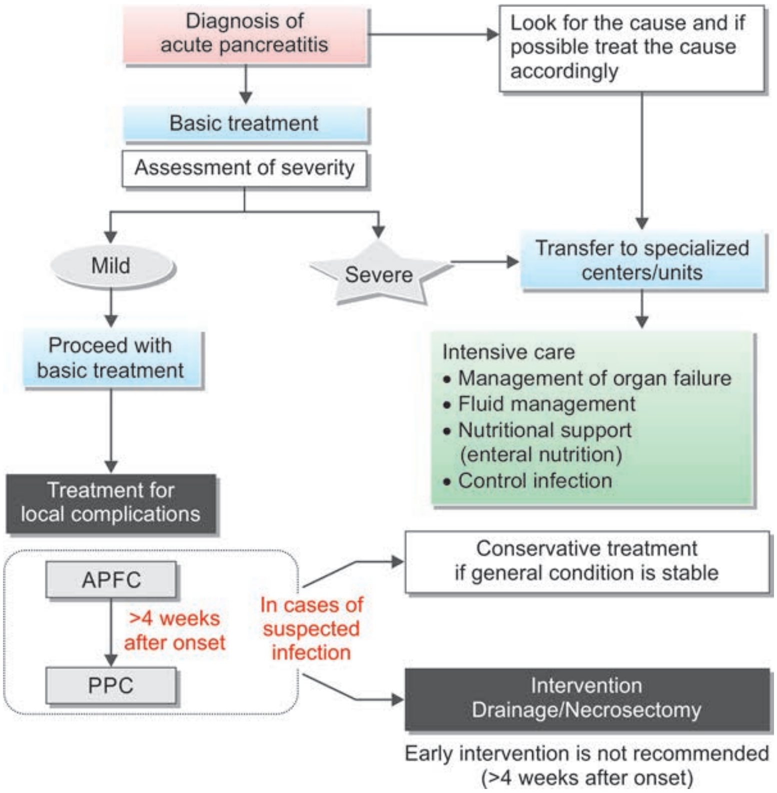
Q. Write short essay/note on causes and complications of chronic pancreatitis.

Pathogenesis

Repeated attacks of acute pancreatitis may lead to chronic pancreatitis. Four models have been suggested which are responsible for the development of chronic pancreatitis.

1. **Obstruction theory:** Some etiological agents cause increase protein concentrations, precipitation of these proteins; form ductal plugs in pancreatic juice. The ductal plugs may calcify to form calculi which further obstruct the pancreatic ducts.
2. **Necrosis-fibrosis theory:** The inflammation and scarring resulting from bouts of acute pancreatitis cause obstruction and stasis within the duct. It may subsequently form stones in the duct.
3. **Toxic-metabolic theory:** Toxins such as alcohol and its metabolites can cause direct toxic damage to acinar cells, and eventually fibrosis.
4. **Oxidative stress theory:** The pancreas is exposed to 'oxidative stress' either through the systemic circulation or through reflux of bile into the pancreatic duct. It also results in recurrent inflammation, tissue damage and fibrosis, and the activation of lysosomes and proenzymes.

FLOWCHART 7.1: Management of acute pancreatitis.



Diagnosis of acute pancreatitis
Look for the cause and if possible treat the cause accordingly
Basic treatment
Assessment of severity
Mild
Severe
Transfer to specialized centers/units
Proceed with basic treatment
Intensive care
• Management of organ failure
• Fluid management
• Nutritional support (enteral nutrition)
• Control infection
Treatment for local complications
APFC
>4 weeks after onset
PPC
In cases of suspected infection
Conservative treatment if general condition is stable
Intervention Drainage/Necrosectomy
Early intervention is not recommended (>4 weeks after onset)

(APFC: Acute peripancreatic fluid collections; PPC: Pancreatic pseudocyst)

TABLE 7.6: Causes of chronic pancreatitis: ***TIGAR-O*** classification system.
Toxic-metabolic ➢ **Alcohol abuse (~70%)** ➢ Tobacco smoking ➢ Hypercalcemia (e.g., hyperparathyroidism) ➢ Chronic renal failure
Idiopathic (~20%) ➢ Tropical/Fibrocalculous pancreatitis
Genetic ➢ Hereditary pancreatitis (cationic trypsinogen mutation) ➢ Cystic fibrosis due to cystic fibrosis transmembrane conductance regulator (CFTR) gene mutations ➢ SPINK1 mutations, mutations in the cationic trypsinogen gene (PRSS1)
Autoimmune ➢ Isolated autoimmune chronic pancreatitis (Type 1—IgG4 related, Type 2— idiopathic duct centric) ➢ Part of multi-organ disorders (Sjögren's syndrome, primary biliary cirrhosis)
Recurrent and severe acute pancreatitis
Obstructive ➢ Duct obstruction (e.g., tumor) ➢ Pancreas divisum ➢ Stenosis of sphincter of Oddi

Clinical Features

Q. Discuss the clinical features of chronic calcific pancreatitis.

- Predominantly affects middle-aged alcoholic men. In southern India, severe chronic calcific pancreatitis may develop in nonalcoholics, probably as a result of *malnutrition and cassava consumption*.
- **Abdominal pain:** Due to increased pressure within the pancreatic ducts and direct involvement of pancreatic and peripancreatic nerves by the inflammatory process. Pain is variable in location, severity, and frequency.
    - May be **continuous or intermittent**.
    - May be **referred to back**.
    - Pain is often increased by eating of heavy meals. This may lead to a fear of eating with consequent weight loss.
    - No uniform relationship between pain and alcohol. Pain may be either exacerbated by alcohol excess or may be relieved by drinking alcohol.
    - It is partially relieved on stooping and bending forwards (Mohammedan prayer sign).
- Features of **maldigestion/malabsorption:** Manifested as chronic diarrhea, **steatorrhea,** weight loss, fatigue.
- **Diabetes mellitus [Pancreatogenic (type 3c) diabetes]** develops in about 30% of patients.
- In late stages, mechanical obstruction of the common bile duct due to fibrosed head of pancreas can produce jaundice.

Physical Examination

Thin, malnourished patient with **tenderness in the epigastric region**.

Investigations

- **Serum amylase and lipase:** May be elevated but in advanced disease they are usually normal.
- **Plain X-ray of abdomen (Fig. 7.5):** May show diffuse **calcifications** in pancreatic area (in ~30%) and usually indicate significant damage to the pancreas.
- **Transabdominal ultrasound scan:** Used for initial assessment.
- **Contrast-enhanced spiral CT scan:** Useful for a more detailed assessment. It may show pancreatic calcification, dilated pancreatic duct, pancreatic atrophy and dilatation/stricture of bile duct.
- **Endoscopic retrograde cholangiopancreatography (ERCP)** is the gold standard for accurate diagnosis and demonstrates pancreatic ducts.
- **MRI with MRCP:** Provides a direct view of the pancreatic duct and detects more subtle abnormalities of the pancreatic duct. **MRI and** MRCP are now the diagnostic procedures of choice.
- **Endoscopic ultrasonography (EUS):** It is useful for specifically assessing complications of chronic pancreatitis including pseudocyst formation and possible development of malignancy.
- **Pancreatic exocrine function tests:**
    - Secretin/cholecystokinin (CCK) stimulation test: Collection of pure pancreatic juice after secretin/CCK injection (gold standard but invasive and seldom used).
    - Fecal chymotrypsin or elastase level: Abnormal in the majority of moderate to severe chronic pancreatitis.
    - 24-hour fecal fat, the Lundh test meal, oral glucose tolerance test and pancreolauryl or para-aminobenzoic acid (PABA) test.
- **Gene mutation analysis:** In cases where the etiology is not known. Common mutations include PRSS1, SPINK-1 and CFTR encoding genes.

Complications of Chronic Pancreatitis

Pseudocyst formation, bile duct or duodenal obstruction, pancreatic ascites or pleural effusion, splenic vein thrombosis, pseudoaneurysms, osteopenia, osteoporosis and pancreatic cancer are the complications of chronic pancreatitis.

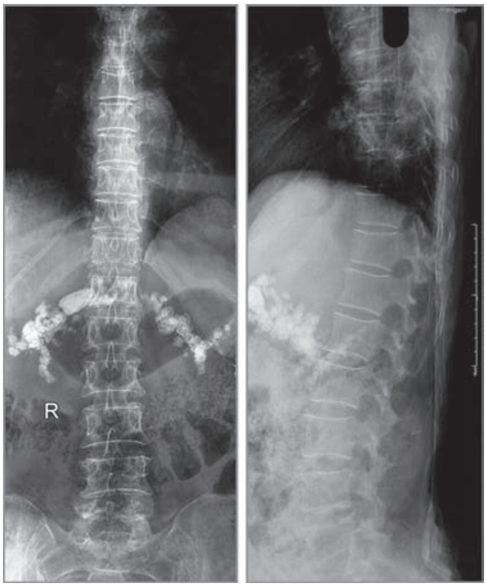


FIG. 7.5: Erect abdominal X-ray AP and lateral views showing calcific pancreatitis.

Treatment

- **Long-term abstinence of alcohol** in patients with alcohol-related chronic pancreatitis may benefit. Smoking cessation prevents progression.
- **Treatment of abdominal pain:** About 60% of patients will become pain-free after about 6–10 years.
  - **Opioids (tramadol) or non-steroidal anti-inflammatory drug (NSAIDs):** Tricyclic antidepressants (e.g., amitriptyline) and membrane stabilizing agents (e.g., pregabalin) may also be used for chronic pain.
  - **Intractable pain** may be treated by **celiac axis nerve block**.
  - **Surgery** includes **pancreatectomy and pancreatojejunostomy** performed for unremitting pain.
  - **Endoscopic therapy** is useful in painful chronic pancreatitis to drain pancreatic duct in patients with obstructed ducts and treatment of complications (e.g., pseudocysts and bile duct obstruction with jaundice).
- **Steatorrhea:**
  - The steatorrhea seen in pancreatic insufficiency may be high, with up to 30 mmol of fat lost/24 h. This is treated with **pancreatic enzymes supplements** particularly lipase, 80,000–1,00,000 units before each meal.
  - An **acid suppressor (H_2-receptor antagonist or proton pump inhibitor)** to prevent inactivation of pancreatic enzymes by gastric acid.
  - Diet rich in **medium-chain triglycerides** which do not require lipase for digestion may be given.
  - Vitamin D supplementation (calcifediol)
- **Treatment of diabetes:** With insulin.

FIBROCALCIFIC/TROPICAL PANCREATITIS

Q. Describe the features of tropical pancreatitis.

- **Juvenile form of chronic calcific pancreatitis** and is **not related to alcohol** intake.
- Almost **exclusively** observed **in tropical countries**. In India, it is more common in southern states namely Kerala and Tamil Nadu.

Etiology

Exact etiology is **not known** and possible risk factors are listed in **Box 7.5**.

Clinical Features

- **Age and gender:** Young males.
- Course: **Accelerated course.**
- **Symptoms: Recurrent abdominal pain**, typically in **epigastric area with radiation to back**. Pain precipitated by heavy meals. Pancreatic exocrine deficiency presents with steatorrhea and malabsorption and endocrine deficiency presents with **diabetes mellitus**. Even without insulin **ketosis is uncommon** and frequent episodes of hypoglycemia with insulin are observed.
- **Signs:** Malnutrition, enlarged parotid glands, abdominal distention and a peculiar cyanotic hue of the lips.

Box 7.5: Risk factors for tropical pancreatitis.

- Malnutrition
- Infections, e.g., coxsackie and viral hepatitis
- Oxidant stress
- Diet rich in cassava, tapioca (contains cyanogenic glycosides)
- Familial.

Investigations

- **Plain X-ray and ultrasound of abdomen:** Shows multiple, large intraductal calculi.
- **Blood:** Sugar, serum amylase, lipids, calcium need to be checked.

Treatment

- Similar to chronic pancreatitis described earlier.
- Insulin for diabetes and requires a careful watch for hypoglycemia.

Differences between Alcoholic Pancreatitis and Tropical Pancreatitis (Table 7.7)

Q. How will you differentiate tropical pancreatitis from alcoholic pancreatitis?

TABLE 7.7: Differences between alcoholic pancreatitis and tropical pancreatitis.

Characteristics	*Alcoholic pancreatitis*	*Tropical pancreatitis*
Age	35–45 years	20–40 years
Gender	Commonly males	Males > females
Steatorrhea	More common	Less common
Diabetes mellitus	Less common	More common
Intraductal calculi	Less common	Frequent
Development of pancreatic malignancy	Less common	More common

TABLE 7.8: HISORt criteria of autoimmune pancreatitis.

Category	*Criteria*
Histology	One of the following:
	Periductal lymphoplasmacytic infiltrate with obliterative phlebitis and storiform fibrosis (LPSP)
	Lymphoplasmacytic infiltrate with storiform fibrosis showing abundant IgG4 positive cells (>10 cells/HPF)
Imaging (CT)/(MRI)	Typical; diffusely enlarged gland with diffuse rim enhancement, diffusely irregular attenuated pancreatic duct
	Other; focal pancreatic mass or enlargement; focal pancreatic duct stricture; pancreatic duct stricture, pancreatic atrophy; pancreatic calcification or pancreatitis
Serology	Elevated serum IgG4 level
Other organ involvement	Hilar/intrahepatic biliary strictures, persistent distal biliary strictures, parotid or lacrimal gland involvement, mediastinal lymphadenopathy or retroperitoneal fibrosis
Response to steroid **t**herapy	Resolution/marked improvement of manifestations with steroid therapy

Autoimmune Pancreatitis (AIP)/Autoimmune Chronic Pancreatitis (ACP)

- Autoimmune pancreatitis is a distinct **chronic inflammatory and sclerosing disease of the pancreas.**
- **Subtypes:**
  - **Type 1—IgG4-related disorder:** It is **one of the IgG4-related disorders** characterized by a **raised serum IgG4 level**. Other IgG4-related disorders are autoimmune cholangitis, Riedel's thyroiditis, aortitis and tubulointerstitial nephritis. Microscopically, IgG4-related disorders show **dense lymphoplasmacytic infiltrate with many IgG4-positive plasma cells**, a mild to moderate infiltration by eosinophils and an obliterative phlebitis in some organs, e.g., pancreas.
  - **Type 2—idiopathic duct-centric pancreatitis or AIP** with a granulocytic epithelial lesion.
- **Age and gender:** It is more **common in men** (2:1) and usually manifests in **middle age** (>85% above the age of 50 years).
- **Clinical presentation:** It presents with **abdominal pain, weight loss** or **painless obstructive jaundice** (due to obstruction of the intrapancreatic bile duct), without acute attacks of pancreatitis. Other symptoms include vomiting, and glucose intolerance.
- **Association with other autoimmune disease:** AIP may also develop in association with other autoimmune disorders. These disorders include Sjögren's syndrome, primary sclerosing cholangitis (PSC), inflammatory bowel disease, retroperitoneal fibrosis (most commonly presenting as hydronephrosis due to entrapment of the ureter).
- **Laboratory findings:** Elevated serum immunoglobulins (IgG or IgG4), and the presence of other autoantibodies including those directed towards nuclear and smooth muscle antigens.
- **Imaging:** It shows diffuse enlargement of pancreas, narrowing of the pancreatic duct and stricturing of the lower bile duct.

The Mayo clinic **HISORt** criteria for the diagnosis of autoimmune pancreatitis **(Table 7.8)**.

Treatment

Glucocorticoid therapy usually produces rather dramatic improvement with rapid resolution of both symptoms and radiographic abnormalities. This is the hallmark of autoimmune pancreatitis. Some patients require azathioprine.

PANCREATIC CANCER

- Pancreatic cancer is the fifth most common cause of cancer death in the Western World.
- **Age and gender:** Its incidence increases with age and the majority occur in the **elderly over the age of 60. Males** are affected twice as often as females.

Etiology

- ***Risk factors:***
  - The most important environmental factor is cigarette smoking.
  - The second most modifiable risk factor is obesity.

  - Excess intake of alcohol, high fat and protein diet, excessive intake of coffee and tea consumption and chronic calcific pancreatitis
  - DM is associate with a 40% ↑ risk of pancreatic cancer.
- **Genetic predisposition:** About 5 to 10% of patients with pancreatic cancer have a family history of the disease. FAMMM (familial atypical multiple mole melanoma syndrome), HNPCC (hereditary nonpolyposis colorectal cancer syndrome), hereditary pancreatitis, MEN, Lynch syndrome and Peutz-Jeghers syndrome have an increased risk of pancreatic cancer.
- Mutational activation of oncogenes, predominantly KRAS, inactivation of tumor suppressor genes such as TP53 (70%), p16/CDKN2A (98%), and SMAD4 (55%) are commonly associated.

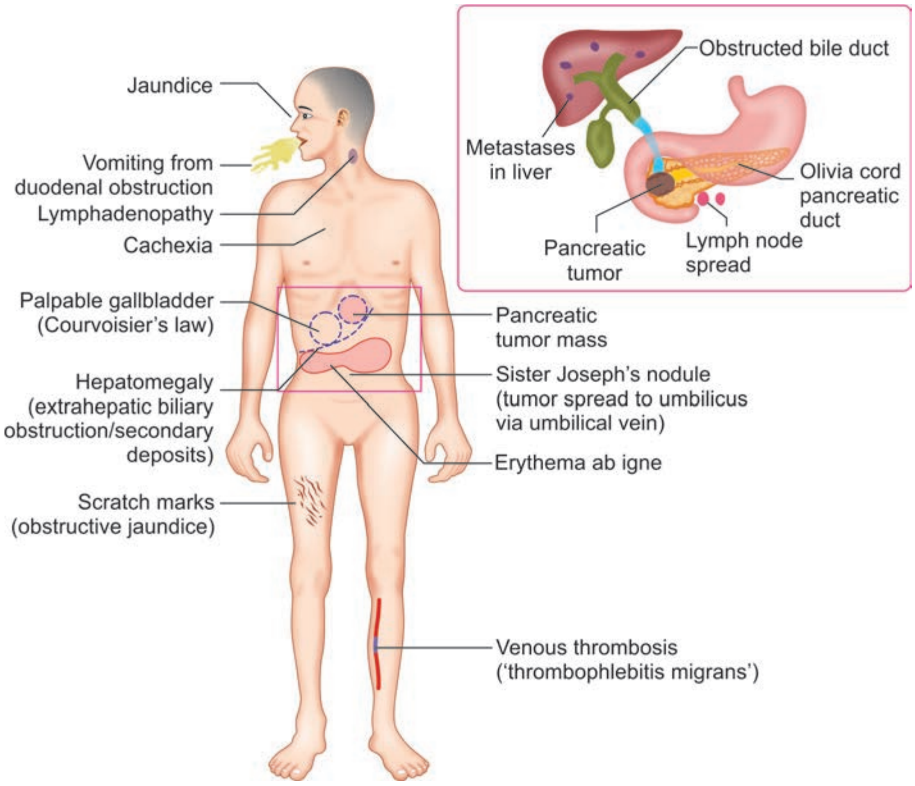
Pathology

- Ductal adenocarcinoma accounts for 85–90% of pancreatic tumors. Cystic neoplasms represent 10%–15% of cystic lesions of the pancreas, 5% are endocrine tumors. Only 2% of tumors of the exocrine pancreas are benign.
- **Location:** About 60–70% of these tumors are localized in the head of the gland, 5–10% in the body, and 10–15% in the tail.
- **Spread:** Local spread, lymphatic spread as well as hematogenous spread occurs rapidly.

Clinical Features (Fig. 7.6)

Symptoms

- **Central abdominal pain:** Pain is common symptom and is usually incessant and gnawing, **epigastric, radiate** from the upper abdomen **to the back**, increasing on lying down and relieved by sitting up or bending forwards. Pain is primarily due to invasion of the celiac or superior mesenteric arterial plexus.
- **Others:** Loss of weight and cachexia.
- Symptoms **depend upon the site of the tumor**.
  - **Carcinoma of the head of pancreas:** They present early because of the obstruction to the common bile duct by the tumor produces **obstructive jaundice** present in >50% of patient (due to obstruction of bile flow), often with severe **pruritus** (secondary to cholestasis). Other symptoms include clay-colored stools with or without melena or silver stools. Obstruction of the pancreatic duct may cause episodes of pancreatitis.



Obstructed bile duct
Metastases in liver
Olivia cord pancreatic duct
Pancreatic tumor
Lymph node spread
Jaundice
Vomiting from duodenal obstruction
Lymphadenopathy
Cachexia
Palpable gallbladder (Courvoisier's law)
Pancreatic tumor mass
Hepatomegaly (extrahepatic biliary obstruction/secondary deposits)
Sister Joseph's nodule (tumor spread to umbilicus via umbilical vein)
Erythema ab igne
Scratch marks (obstructive jaundice)
Venous thrombosis ('thrombophlebitis migrans')

FIG. 7.6: Features of carcinoma of the pancreas.

  - Less common symptoms include those of diabetes and pancreatitis.
  - **Carcinoma of the body and tail of the pancreas: May be silent** till quite large and widely disseminated.

Physical Signs

- **General: Pallor, jaundice** and weight loss may be present. Scratch marks and **erythema ab igne** is seen.
- **Abdominal mass: A mass may be felt** in the epigastrium; the liver may be enlarged (hepatomegaly) due to biliary obstruction or secondary involvement (hepatic metastasis).
- **Courvoisier's law:** A distended nontender gallbladder may be palpable in a jaundiced patient due to distal biliary obstruction by a pancreatic cancer.
- **Due to spread of tumor:**
  - With peritoneal involvement and **ascites**, shifting dullness and fluid thrill can be elicited. On per rectal examination, nodules (**Blumer's shelf**) or peritoneal fluid may be felt.
  - Involvement of the left supraclavicular node (**Virchow's node**) and umbilicus (**Sister Mary Joseph's nodules**) indicates advanced carcinoma.
- **Other presenting physical signs:** Migratory thrombophlebitis—recurrent venous thrombosis (**Trousseau sign**), diabetes, polyarthritis, paraneoplastic syndromes (Cushing syndrome), skin nodules (secondary to localized fat necrosis and associated inflammation) and hypercalcemia may be seen in some cases.

Investigations

- **Blood:** It may show anemia. Liver function tests may show features of obstructive jaundice with elevated alkaline phosphatase. Urobilinogen is absent in urine whereas bile salts and bile pigments are evident. Occult blood may be present in stool.
- **Radiology: Barium meal** shows widening of the 'C' loop (**pad sign**) and reverse '3' sign in periampullary carcinoma. Hypotonic duodenography reveals a 'rose thorn' appearance. Endoscopic retrograde cholangiography increases the diagnostic yield; USG and CT scan are helpful in localizing the tumor.
- Ultrasound, contrast CT and ERCP yield in localization of tumor, assessing the spread as well as operability, guided biopsy/cytology helps to confirm diagnosis.
- **ERCP:** A "double-duct sign," representing strictures in biliary and pancreatic ducts, is classically found in many patients. Tissue sampling can also be obtained during ERCP.
- Endoscopic ultrasonography is the most accurate test for the detection of pancreatic cancer.
- **Tumor markers:** Carcinoembryonic antigen (CEA) and **CA-19-9** [high sensitivity (80%) but a high false-positive rate].

Prognosis

Overall survival is about 3–5%, with median survival of 6–10 months for locally advanced cancer and 3–5 months for those with metastases.

Treatment

- **Surgical resection:** It is the only method of effecting cure. Resectable tumors in the head and periampullary region are removed by Whipple's pancreaticoduodenectomy or its modifications.
- **Chemotherapy:** For inoperable cases chemotherapy with gemcitabine, capecitabine, paclitaxel, cisplatin, docetaxel, oxaliplatin, irinotecan, 5-fluorouracil, mitomycin, streptozotocin and high-dose methotrexate, alone or in combination, may be beneficial. Tyrosine kinase inhibitors of EGFR (e.g., erlotinib) and monoclonal antibodies cetuximab is under trials.
  - FOLFIRINOX is a chemotherapy regimen for treatment of advanced pancreatic cancer (FOL – folinic acid (leucovorin), F – fluorouracil (5-FU), IRIN – irinotecan, OX – oxaliplatin)
- Radiotherapy may be supportive.
- **Palliative treatment:**
  - **Pain:** Palliation for pain may be achieved with either analgesic nerve blocks (coeliac axis block/neurolysis, percutaneous cordotomy) or with duct drainage (pancreaticogastric anastomosis).
  - Jaundice can be relieved by choledochojejunostomy or percutaneous/endoscopic stenting—endoprostheses (elderly and with very advanced disease).

ENDOCRINE TUMORS OF PANCREAS/PANCREATIC NEUROENDOCRINE TUMORS (PNETs)

- Endocrine tumors of pancreas (ETP) are classified as functioning or nonfunctioning according to the type and level of their hormonal secretion.

- Among functioning ETP, insulinomas (50%) and gastrinomas (30%) are the most frequent; tumors secreting vasoactive intestinal peptide (VIPomas), glucagon (glucagonomas), and somatostatin (somatostatinomas) are much rarer (5–10%). These secreting growth-hormone-releasing factor (GHRH), adrenocorticotropic hormone (ACTH) or corticotropin-releasing factor (CRF), and parathyroid hormone related peptide (PTHrp) are anecdotal.
- Conversely, at least 15% of ETP are nonfunctioning or secrete nonclinically active peptides such as human pancreatic polypeptide (PPomas).

Insulinoma (Beta Cell Tumor)

Most common of endocrine tumors; **10% are malignant** and produce pronounced hypoglycemia.

Clinical Features

- Higher incidence in **women**.
- **Whipple's triad (Box 7.6)**.

Box 7.6: Whipple's triad.

- **Attack of hypoglycemia** (mental confusion, weakness, fatigue and convulsions) **while fasting.** Neuroglycopenic symptoms (anxiety, nervousness, dizziness and confusion) may develop during fasting. In some psychoses, seizures related to hypoglycemia and weight gain is seen.
- **Blood sugar <50 mg/dL during an attack.**
- **Relief of symptoms by administration of glucose**.

Diagnosis

Fasting blood levels of insulin and glucose:

- **Inappropriately elevated serum level of insulin** (>54 u/mL) for the level of glucose **establishes the diagnosis**.
- Blood **insulin-to-glucose ratio of >0.4 is diagnostic**.
- Blood fasting **C-peptide level** of >1.7 mg/mL is a good indicator.
- **Proinsulin level** is elevated and is used as a tumor marker.
- Suppression and stimulation (tolbutamide, calcium, glucagon) tests may be performed.

Radiology

- **Selective angiography** is best investigation, with few false positive results.
- **USG** is positive in 20–40% of cases.
- **CT with intravenous contrast** shows a dense blush.
- **MRI:** Bright spots are seen on T2 weighted images. In the presence of somatostatin receptors, octreotide scan may be useful. Portal venous sampling has 75% accuracy.
- **Calcium angiography:** It can determine the location of insulinoma whereas endoscopic USG has 80% positivity.

Treatment of Insulinoma

- **Aim:** To localize and remove the tumor safely.
- **Hypoglycemia** can be **managed medically** (by using diazoxide, octreotide, lanreotide).
- **Surgery:**
  - If tumor is **small** and in the **head**: Removed by **enucleation.**
  - If in the **body or tail**: Remove it either by **enucleation** or by **distal** (subtotal) **pancreatectomy**.
  - If the tumor is **malignant and is operable**: **Resection**.
- **For metastasis** (liver, adjacent lymph nodes):
  - Hepatic artery embolization, RFA and cryoablation or radioembolization.
  - Streptozotocin, chlorozocin, 5-FU, either alone or in combination.

Gastrinoma (Delta Cell Tumor)

(Synonym: Zollinger-Ellison syndrome)

Second most common islet cell tumor (0.1–0.4/million population/year), but with MEN I it is the most common functional pancreatic neoplasm; 20% of ZES have MEN I.

Q. Write short essay/note on etiology, clinical features and treatment of Zollinger-Ellison syndrome.

Pathology

- **Sites:** Most common site of gastrinoma is duodenum (50-88% in sporadic ZES, 70-100% in MEN I ZES), pancreas (only 25%, and rarely in gastric antrum).
- **Effects:** It produces excessive gastrin.

- **Characteristics:**
    - Often **solitary and malignant**.
    - When occurs as part of **MEN I, they are multiple and less malignant**.
    - Duodenal gastrinomas are less malignant than pancreatic tumors. They are slow growing even in the presence of metastasis.

Gastrinoma Triangle of Passaro (Fig. 7.7)

1. Junction between the cystic duct and common bile duct
2. Junction between the 2nd and 3rd parts of the duodenum
3. Junction between neck and body of pancreas 60–90% of gastrinomas arise within this triangle.

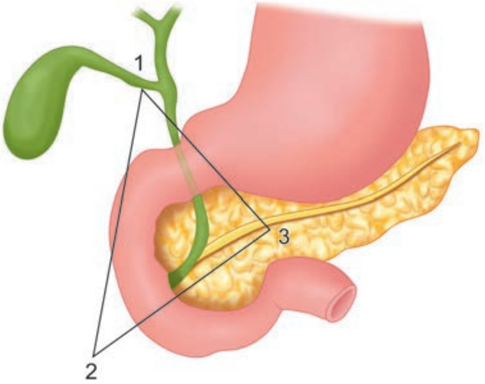


FIG. 7.7: Gastrinoma triangle.

Clinical Features

- More frequent in **middle-aged men**. With MEN I, the symptoms occur earlier (3rd decade).
- **Zollinger-Ellison syndrome** is characterized by **hyperacidity and nonhealing ulcers** (gastric, duodenal, jejunal, or in atypical locations). Epigastric pain with duodenal ulcer is seen in 90% of cases; 1/3rd have diarrhea, and weight loss is common (40% of cases). Esophagitis, dysphagia (30%), stricture and perforation may occur.

Diagnosis

- **ZES:** About 30–40% do not have evidence of peptic ulcer disease and 40% have duodenal instead of pancreatic tumor.
- **Gastric acid hypersecretion** (basal acid output >15 mEq/L) and **elevated fasting gastrin** (>100 pg/mL) are suggestive. Provocative tests using secretin, calcium or gastrin may be used. Gastric pH <2 and fasting serum gastrin level >1000 pg/mL is diagnostic.
- **Immunohistochemistry:** Demonstration of gastrin in neoplastic cells by immunoperoxidase is confirmatory.
- **Tumor localization:** Using ultrasound, CT scan and endoscopic USG.
    - **Selective angiography** is best for primary and metastatic gastrinomas (40–60% accuracy) and with secretin stimulation, the accuracy increases to 70%.
    - Portal venous sampling for gastrin.

Treatment

Medical

Control acid secretion using H_2 blockers. Dose: 2 grams ranitidine, 0.3 g famotidine or 80 mg omeprazole/pantoprazole per day. Parenteral ranitidine may be used.

Surgery

- Accurately **identification of duodenal or pancreatic tumor** by inspection, palpation and if needed by intraoperative USG or transillumination duodenotomy.
- Surgical management: Excision, gastrectomy, enucleation based on tumor size, number and location.
- **Patients with MEN I having gastrinoma:**
    - **Surgery is not indicated**.
    - Four-gland parathyroidectomy with autografts is the initial procedure of choice to control hyperparathyroidism. Gastric acid hypersecretion is controlled as in sporadic gastrinoma (mentioned above).
    - If liver metastasis is present and resectable: Resection.
    - Chemotherapy: Doxorubicin, 5-FU, streptozotocin shows 40% response. Interferon and octreotide may also be used.

Glucagonoma (Alpha Cell Tumor)

Rare α-cell tumor.

Clinical Features

- Functional tumors: They produce the **glucagonoma syndrome** comprising abnormal glucose tolerance test, normocytic normochromic anemia, necrolytic migratory erythema (pathognomonic), red tongue, angular stomatitis, weight loss, tendency to develop infection, and depression.
- **Elevated fasting plasma glucagon >500 pg/mL is diagnostic**.

Treatment: Preoperative control of diabetes, treatment of venous thrombosis and correction of nutritional status with total parenteral nutrition. Surgical resection is done after localizing the tumor.

Somatostatinoma (Delta Cell Tumor)

Rare malignant D cell tumors of the pancreas and 30% occur in the duodenum and small bowel. They affect both the sexes equally, with approximate age of 50 years. They cause diabetes mellitus, gallstones and diarrhea/steatorrhea.

Diagnosis: High fasting serum somatostatin levels.

Treatment: Octreotide therapy may be tried and the tumor surgically resected after localization. Cholecystectomy may be required for cholelithiasis.

VIPoma (WDHA Syndrome; Verner-Morrison Syndrome; Pancreatic Cholera)

- Endocrine pancreatic tumor producing vasoactive intestinal polypeptide (VIP).
- **Symptoms:** Severe secretory diarrhea secondary to the stimulation of adenyl cyclase within the enterocyte (Verner–Morrison syndrome). Large-volume diarrhea (>3 L/day), hypokalemia, and hypo- or achlorhydria form part of the syndrome; hence the term **W**atery **D**iarrhea, **H**ypokalemia, **A**chlorhydria (WDHA) syndrome.

Diagnosis: Presence of severe secretory diarrhea, detection of elevated fasting levels of plasma VIP (>250 pg/mL) and localization of pancreatic islet cell tumor.

Treatment

- Correction of dehydration, hypokalemia and other metabolic abnormalities.
- Octreotide may be tried for symptomatic relief.
- Surgical removal of the tumor.
- For unresectable and metastatic tumors chemotherapy with 5-FU and streptozotocin. Interferon has also been used. Palliative debulking for incurable and metastatic tumors.

CHAPTER

8

Rheumatology and Connective Tissue Disorders

INTRODUCTION

Rheumatology is a branch of medicine that deals with the diagnosis and management of disorders affecting the joints, muscles, bones, and connective tissues. It involves the diagnosis and treatment of rheumatic diseases, which include a wide range of conditions such as arthritis, lupus, fibromyalgia, gout, and vasculitis.

Immunology, on the other hand, is the study of the immune system and its function in defending the body against infections, diseases, and foreign substances.

Given the complex nature of many rheumatic diseases, there is a significant overlap between rheumatology and immunology. Autoimmune diseases, such as rheumatoid arthritis, systemic lupus erythematosus (SLE), and vasculitis, involve aberrant immune responses targeting the body's own tissues. These diseases require an understanding of both the immune system and the musculoskeletal system for accurate diagnosis and optimal treatment.

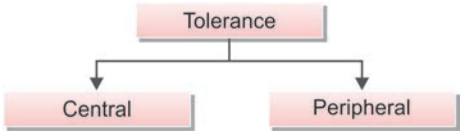
Q. What is the origin of connective tissue disorders?

- 1942—Dr Klemperer introduces the term diffuse collagen disease based on his pathologic studies of systemic lupus erythematosus and scleroderma.
- 1946—Dr Rich coins the term collagen vascular disease based on his pathologic studies in vasculitis, indicating that the primary lesion involved the vascular endothelium.
- 1952—Dr Ehrich suggested the term connective tissue diseases, which has gradually replaced the term collagen vascular diseases.

In summary, the two terms are used synonymously.

Q. IM7.1 Describe the pathophysiology of autoimmune disease.

- To understand the basis of autoimmune disease, first it is essential to be familiar with the concept of tolerance.
- **Tolerance** is the term used to describe the phenomenon of **antigen-specific unresponsiveness.** In other words, the immune system encounters certain antigens to which it is programmed specifically to not respond and, therefore, not eradicate.
- This phenomenon is present in both innate and adaptive immune response. When the individual's own adaptive immune system fails to recognize his/her own nucleoproteins or cell surface molecules as self and mounts an immune response against those antigens, this is termed as **autoimmunity** and **loss of 'self-tolerance'.**
- There are various mechanisms and processes involved in the development and maintenance of tolerance to self-antigens. They can be divided into



Central tolerance:

- **Thymic selection of T cells (clonal deletion)**: The T cells which react strongly to major histocompatibility complex (MHC) self-antigens are eliminated during negative selection in the thymus. This is under control of autoimmune regulator (AIRE) gene.

  - **Receptor editing of B cell receptors:** This occurs in the bone marrow during B cell maturation. The B cells which recognize self-antigens in the bone marrow are subjected receptor editing, where they actively rearrange genes to express new receptors that no longer react to self-antigens. If this fails, then they undergo apoptosis.

  Peripheral tolerance:
  - **Clonal anergy**: The self-reactive T cells which encounter self-antigens presented by HLA molecules, are stopped from generating an immune response by the absence of co-stimulatory molecules and thus remain unresponsive.
  - **Immunological ignorance**: Similar to B cell receptor editing, peripheral T cells may not have a TCR that reacts strongly enough with MHC-self-antigen complex.
  - **Suppression by regulatory T cells**: These Treg cells suppress self-reacting T cells by various mechanisms. Their activity is mediated by interleukin 10 (IL-10) and transforming growth factor beta (TGF-β).
- **Autoimmunity:** This term is used to describe those conditions where self-tolerance is broken and the body mounts an immune response against self-antigens. In an ideal scenario, there are at least three requirements which should be met before a disorder is termed as autoimmune:
  i. An immune reaction specific to a self-antigen
  ii. This reaction should not be secondary to tissue damage and is the primary pathology.
  iii. There should be a clear absence of another well-defined cause of the disease.
- **Mechanisms involved in pathogenesis of autoimmune diseases**: There are several mechanisms that have been hypothesized and all of them center on the principle of a genetically susceptible host who has one or more incidental environmental exposures which together result in the disease.
  - **Superantigens:** These are certain bacterial and viral antigens that have the unique ability to bind to MHC molecules outside the antigen binding cleft and stimulate T cell receptors in the V region of the β chain.
  - **Molecular mimicry**: Exogenous antigens may sometimes share structural similarity with self-antigens. Antibodies produced against these exogenous antigens will cross react with host antigen.
  - **Cytokine dysregulation**: Abnormally increased or aberrant cytokine production by the innate immune system may trigger the adaptive immune system to reactivate anergic self-reactive T cells and results in autoimmune response.
  - **Neoantigen formation and cryptic epitope exposure:** Post-translational editing of antigens or changes that occur due to cellular stress or injury (where the earlier concealed antigens are now exposed) may result in new antigens that were not previously subjected to tolerance and hence will result in anti-self-immune response.

Q. IM7.2 Describe the genetic basis of autoimmune disease.

Autoimmune diseases are a diverse group of disorders that occur when the immune system mistakenly attacks healthy cells and tissues in the body. These conditions can affect various organs and systems, leading to chronic inflammation and tissue damage. While the exact causes of autoimmune diseases remain elusive, researchers have identified a significant genetic component that contributes to their development. The genetic basis of autoimmune diseases are complex interplay between genetic factors and the immune system.

- **Genetic factors in autoimmunity**:
  - **Genetic predisposition** plays a crucial role in the development of autoimmune diseases. Numerous studies have shown that individuals with a family history of autoimmune disorders have a higher risk of developing these conditions. The heritability estimates for autoimmune diseases range from moderate to high, indicating that genetic factors substantially contribute to their occurrence.
  - **Human leukocyte antigen (HLA) genes** have been extensively implicated in autoimmune diseases. HLA genes encode proteins that help the immune system identify self from non-self. Certain variants of HLA genes, known as alleles, have been linked to an increased susceptibility to specific autoimmune diseases. For instance, **the HLA-DRB1*15:01** allele is associated with an elevated risk of **multiple sclerosis**, while **HLA-B27** is strongly associated with **ankylosing spondylitis**.
  - **Single nucleotide polymorphisms (SNPs):** Apart from HLA genes, other genetic variations have been identified as risk factors for autoimmune diseases. **Genome-wide association studies (GWAS**) have identified numerous **single nucleotide polymorphisms (SNPs)** that are associated with different autoimmune conditions. These SNPs are located in genes involved in immune regulation, such as cytokines, signaling molecules, and immune cell receptors. These genetic variants contribute to dysregulated immune responses, promoting autoimmunity.
- **Gene-environment interactions:**
  - While genetic factors are important, they alone do not explain the development of autoimmune diseases. Gene-environment interactions also play a crucial role. Certain environmental triggers, such as infections, toxins, and hormonal changes, can activate the immune system and initiate autoimmune responses in genetically susceptible individuals.

  - **Epigenetic modifications**, which are changes in gene expression without altering the underlying DNA sequence, further illustrate the interaction between genetics and the environment in autoimmune diseases. Environmental factors can modify epigenetic marks, influencing the activation or silencing of genes involved in immune regulation. These changes can alter the immune response and increase the risk of developing autoimmune conditions.
- **Complex nature of autoimmune diseases**:
  - Autoimmune diseases are characterized by their complex nature. They exhibit heterogeneity in terms of clinical presentation, disease progression, and response to treatment. This complexity can be attributed to the involvement of multiple genetic and environmental factors, as well as the interplay between different components of the immune system.
  - **Polygenic inheritance is a common feature of autoimmune diseases**, meaning that multiple genetic variants contribute to disease susceptibility. These variants may have small individual effects but collectively increase the risk of developing autoimmunity. Moreover, different autoimmune diseases share overlapping genetic risk factors, suggesting common pathways and mechanisms underlying their development.

In conclusion, the genetic basis of autoimmune diseases is a fascinating and rapidly evolving field of research.

Q. IM7.3 Classify cause of joint pain based on pathophysiology.

Q. IM7.4 Develop a systematic clinical approach to joint pain based on pathophysiology.

On the basis of pathophysiology, joint pain can be classified roughly into 4 causes: Inflammatory, Mechanical, Infectious and Crystal-induced.

Approaching joint pain based on pathophysiology involves understanding the underlying mechanisms and causes of joint pain in order to guide appropriate diagnosis and treatment.

1. Inflammatory Joint Pain

Inflammatory joint pain is commonly associated with autoimmune diseases such as rheumatoid arthritis, SLE, and psoriatic arthritis. It is characterized by joint swelling, warmth, and morning stiffness that improves with activity. The approach to inflammatory joint pain includes:

Medical history and physical examination: Assess for signs of inflammation, such as swollen joints, limited range of motion, and tenderness.

Laboratory tests: Conduct tests for markers of inflammation, such as erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and autoimmune antibodies (e.g., rheumatoid factor and anti-cyclic citrullinated peptide).

Imaging studies: X-rays, ultrasounds, or magnetic resonance imaging (MRI) can help evaluate joint damage and inflammation.

Treatment: Nonsteroidal anti-inflammatory drugs (NSAIDs), disease-modifying antirheumatic drugs (DMARDs), and biologic therapies may be used to control inflammation and manage symptoms.

2. Mechanical Joint Pain/Degenerative

Mechanical joint pain is usually related to structural or biomechanical issues within the joint. It is commonly seen in osteoarthritis, joint injuries, or overuse conditions. The approach to mechanical joint pain includes:

History and physical examination: Gather information about the onset, location, aggravating factors, and relieving factors of the pain. Assess for joint instability, crepitus, and limited range of motion.

Imaging studies: X-rays, CT scans, or MRIs can help visualize joint structure, cartilage loss, and bone abnormalities.

Treatment: Management may include physical therapy, weight management, assistive devices, pain relief medications (such as acetaminophen or NSAIDs), and joint injections (corticosteroids or hyaluronic acid).

3. Infectious Joint Pain

Infectious joint pain arises from joint infections, such as septic arthritis or reactive arthritis following an infection. The approach to infectious joint pain includes:

History and physical examination: Evaluate for signs of infection, such as fever, localized warmth, redness, swelling, and limited joint mobility.

Laboratory tests: Perform blood tests, joint fluid analysis, and cultures to identify the causative organism.

Imaging studies: X-rays or MRI may help assess joint damage and identify potential sources of infection.

Treatment: Prompt administration of antibiotics or antivirals is crucial in managing infectious joint pain. In some cases, surgical drainage or joint lavage may be necessary.

4. Crystal-induced Joint Pain

Crystal-induced joint pain occurs when crystals, such as uric acid (in gout) or calcium pyrophosphate dihydrate (in pseudogout), accumulate in the joints, leading to inflammation. The approach to crystal-induced joint pain includes:

History and physical examination: Assess for sudden onset of joint pain, redness, swelling, and a history of recurrent attacks.

Laboratory tests: Analyze joint fluid for crystal identification and measure serum uric acid levels.

Imaging studies: X-rays or ultrasound can help identify crystal deposits and joint damage.

Treatment: Medications for pain relief, anti-inflammatory drugs (NSAIDs, colchicine), and lifestyle modifications (such as dietary changes and weight management) are commonly used to manage crystal-induced joint pain.

Q. IM7.5 **Describe and discriminate between acute, subacute and chronic causes of joint pain.**

Acute Joint Pain

Acute joint pain refers to sudden-onset pain that lasts for a relatively short duration, **usually less than six weeks**. It may occur due to various reasons, including:

- **Joint injuries:** Traumatic injuries, such as fractures, dislocations, sprains, or strains, can cause acute joint pain.
- **Infections:** Joint infections, such as septic arthritis, can lead to sudden and severe joint pain along with other symptoms like swelling, redness, and warmth.
- **Gout or pseudogout attacks:** These crystal-induced arthritic conditions can cause sudden, intense joint pain that typically affects one joint, often the big toe (in gout) or the knee (in pseudogout).
- **Bursitis:** Inflammation of the fluid-filled sacs (bursae) that cushion the joints can result in acute joint pain.

Prompt evaluation and appropriate management are crucial for acute joint pain to prevent further damage and facilitate recovery.

Subacute Joint Pain

Subacute joint pain refers to pain that persists for a longer duration than acute pain, typically between **six weeks and three months**. It falls between acute and chronic pain in terms of duration and progression. Causes of subacute joint pain may include:

- **Persistent or unresolved acute joint injuries:** In some cases, joint pain may linger beyond the acute phase, indicating a subacute stage.
- **Certain infections:** Some infectious joint conditions may have a subacute presentation, with symptoms persisting for several weeks.
- **Early stages of chronic conditions:** Subacute joint pain may be a manifestation of the initial stages of chronic conditions, such as rheumatoid arthritis or osteoarthritis.

A thorough evaluation and appropriate management are necessary to determine the underlying cause of subacute joint pain and prevent further progression.

Chronic Joint Pain

Chronic joint pain refers to persistent or long-lasting pain that lasts for **more than three months**. It may continue for months to years and can have a significant impact on an individual's daily life. Causes of chronic joint pain may include:

- **Chronic inflammatory conditions:** Conditions like rheumatoid arthritis, SLE, psoriatic arthritis, or ankylosing spondylitis can result in persistent joint pain.
- **Osteoarthritis:** Chronic joint pain is a hallmark of osteoarthritis, a degenerative joint disease that involves the gradual breakdown of joint cartilage.
- **Joint overuse or repetitive stress:** Chronic joint pain can develop because of repetitive activities or overuse, such as in certain occupational settings or sports.
- **Persistent joint injuries:** Some joint injuries may lead to long-lasting pain, particularly if they were not adequately treated or if there is underlying joint damage.

Management of chronic joint pain often requires a multidisciplinary approach involving pain management strategies, physical therapy, lifestyle modifications, and appropriate medications.

Q. Prioritize based on clinical features for arriving at an etiological diagnosis in polyarthritis.

Clinical approach to polyarthritis is important and the diagnosis is often challenging due to the extensive differential diagnosis. Thorough history and physical examination are the cornerstone for diagnosis. The clinical factors helpful in narrowing the diagnosis are the ***chronology of symptoms***, ***features of inflammation, joint distribution***, ***extra-articular manifestations***, ***disease course*** and ***patient demographics***.

- **Chronology**
    - Acute polyarthritis may be due to a self-limited disease.
    - It could be due to infectious, crystal induced or reactive causes.
    - Rarely chronic polyarticular arthritides, like rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) can have acute presentation in the early course of illness.
    - Chronic arthritis may be due to immunologic arthritides like RA, noninflammatory and nonarticular causes.
- **Inflammation**
    - Features of inflammation make it inflammatory arthritis and in the absence, it is called athralgia.
    - Erythema, warmth, pain and swelling are the cardinal features of inflammation. Fatigue, fever and weight loss can also be present.
    - Morning stiffness lasting for longer than an hour is another clue.
    - Palpate the joint capsule for synovial thickening, soft tissue swelling effusions.
    - Presence of crepitus indicates underlying injury, osteoarthritis (OA) or previous inflammation. Heberden's and Bouchard's nodes indicate osteoarthritis.
    - Subjective sense of swelling without objective sign of synovitis is seen in patients with fibromyalgia.

Q. IM7.8, 7.13 Determine the potential causes of joint pain based on the presenting features of joint involvement.

- **Joint distribution**
    - Crystal and infectious arthritides are often mono or oligoarticular whereas OA and RA are polyarticular.
    - Joint involvement in RA tends to be symmetrical and polyarticular whereas spondyloarthropathy, gout and reactive arthritis involvement is asymmetric and oligoarticular.
    - Psoriatic arthritis and OA can be either mono or polyarticular and symmetric or asymmetric.
    - Upper extremities are commonly affected in RA and OA, whereas lower extremities are affected commonly in reactive arthritis, spondyloarthropathies and gout.
    - Axial skeleton is involved in ankylosing spondylitis (SpA) and OA. Osteoarthritis usually spares wrist, elbow and ankle unless there is a past history of trauma.
    - Osteoarthritis involves distal interphalangeal (DIP) and proximal interphalangeal (PIP) joints with sparing of metacarpophalangeal joints. Rheumatoid arthritis spares DIP but affects PIP and metacarpophalangeal (MCP) joints. Psoriasis and crystal arthropathies affect all three joints.
- **Extra-articular manifestations**
    - SLE can present with malar rash and oral ulcers.
    - Psoriatic skin and nail changes accompany psoriatic arthritis.
    - Polymyositis is suggested by proximal muscle weakness.
    - Reactive arthritis is suggested by a history of recent gastrointestinal or genitourinary infection, conjunctivitis and oral ulcers.
    - Spondyloarthropathies can present with enthesitis or dactylitis causing sausage-shaped digits.
- **Disease course**
    - Intermittent arthritis is a feature of crystal arthropathies, Lyme arthritis and palindromic rheumatism that may progress to rheumatoid arthritis later.
    - Migratory arthritis can be a feature of rheumatic fever, bacterial endocarditis, gonococcal infection and viral fever.
- **Patient demographics**
    - Incidence of RA, SLE, fibromyalgia are more among premenopausal women compared to men of same age group.
    - Spondyloarthropathies occur equally in males and females.
    - Gout usually occurs 20 years after puberty in men and 20 years after menopause in women. Rare among premenopausal women unless associated with renal failure.
    - RA, SLE, reactive arthritis and spondyloarthropathies occur more among younger individuals whereas OA, polymyalgia rheumatic and giant cell arthritis occur more among elderly.
    - Family history is important in spondyloarthropathies, rheumatoid arthritis and Heberden's nodes of osteoarthritis.

Table 8.1 discusses the classification of arthritis with examples.

TABLE 8.1: Classification of arthritis with examples.

Musculoskeletal complaint					
Distribution					
	Polyarthritis (≥4 joints)		***Monoarthrltis /Oligoarthritis (1-3 joints)***		***Nonarticular***
	Acute	***Chronic***	***Acute***	***Chronic***	
Non-inflammatory	➢ Hemoglobinopathies ➢ Amyloid arthropathies	➢ Osteoarthritis	➢ Meniscal tear ➢ Osteoarthritis flare ➢ Reflex sympathetic dystrophy	➢ Osteoarthritis ➢ Osteonecrosis ➢ Neuropathic arthritis ➢ Hemochromatosis ➢ Pigmented villonodular synovitis	➢ Trauma ➢ Fracture ➢ Fibromyalgia ➢ Reflex sympathetic dystrophy
Inflammatory	➢ Viral arthritis ➢ Serum sickness ➢ Drug induced arthritis ➢ Early onset connective tissue disease (CTD) ➢ Rheumatic fever ➢ Palindromic rheumatism ➢ Remitting seronegative symmetrical synovitis with pitting edema (RS3PE)	➢ Rheumatoid arthritis ➢ Undifferentiated polyarthritis ➢ Inflammatory osteoarthritis ➢ Mixed connective tissue disease ➢ Lupus, scleroderma ➢ Polyarticular juvenile idiopathic arthritis (JIA) ➢ Adult Still's disease	➢ Infectious arthritis ➢ Gout ➢ Pseudogout ➢ Reactive arthritis ➢ Chlamydial arthritis	➢ Psoriatic arthritis ➢ Spondyloarthropathies ➢ Pauciarticular JIA ➢ Indolent infectious arthritis	➢ Bursitis ➢ Tendinitis ➢ Polymyalgia rheumatica

IM7.6 Differences between inflammatory versus noninflammatory arthritis is presented in **Table 8.2**.

TABLE 8.2: Inflammatory versus noninflammatory arthritis.

Features	***Inflammatory (rheumatoid arthritis)***	***Noninflammatory (osteoarthritis)***
Age of onset	Usually 20 to 40 years but may begin at any age	Most commonly over 50 years of age
Speed of onset	Rapid over weeks to months	Slow; over years
Systemic symptoms	Fatigue, low-grade fever, anorexia. Extra-articular manifestations: rheumatoid nodules, Sjögren's syndrome, Felty syndrome	No systemic symptoms
Joint affection	Symmetrical	Asymmetrical
Joint symptoms	Painful, swollen stiff joints and muscle aches	Joints painful without swelling
Joints involved	Primarily affects small joints [metacarpophalangeal (MCP) and proximal interphalangeal (PIP)]	Affects large weight-bearing joints (hip, knee or the spine). Affects proximal interphalangeal (PIP) and distal interphalangeal (DIP) joints
Stiffness	Morning stiffness for >1 hour. Stiffness occurs after periods of rest/inactivity (the so-called 'gel phenomenon')	Morning stiffness for <30 minutes. Stiffness is generally mild and occurs after periods of activity
Relation of movement with pain	Movement or mild to moderate activity decreases pain	Movement increases the pain (worsens with activity) and improves with rest
Examination of joint	Swollen, red, warm, tender and painful	Swollen, cool and hard on palpation. When severely inflamed (as in acute gout or septic arthritis), can have erythema of the overlying skin
Radiological findings	Bony erosion, soft tissue swelling, angular deformities, periarticular osteopenia	Loss of joint space and articular cartilage, routine wear and tear, osteophytes
Laboratory findings		
Rheumatoid factor (RF), antinuclear antibody	Positive	Negative
Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)	Both are often raised	Usually normal but transient elevation of ESR may occur due to synovitis
White blood cell (WBC) count in the synovial fluid	WBC count is >2000/mm^3 in septic arthritis and not in rheumatoid arthritis	– <2000/mm^3

Q. IM7.6 Discriminate, describe and discuss arthralgia from arthritis.

Arthritis and arthralgia are related terms that refer to different aspects of joint pain.

Arthritis: Arthritis refers to inflammation of one or more joints, which can result in joint pain, stiffness, swelling, and reduced range of motion. It is a broader term that encompasses various conditions affecting the joints. There are different types of arthritis, including:

- Osteoarthritis (OA)
- Rheumatoid arthritis (RA)
- Psoriatic arthritis
- Gout

Arthralgia: Arthralgia refers to joint pain without significant joint inflammation or swelling. It is a symptom rather than a specific condition or disease. Arthralgia may be caused by various factors, such as injury, overuse, trauma, or other underlying medical conditions. Common causes of arthralgia include:

- **Joint sprains or strains:** Injuries to ligaments, tendons, or muscles around a joint can result in joint pain without joint inflammation.
- **Overuse or repetitive strain:** Repeated motions or excessive use of a joint, such as in certain occupational activities or sports, can lead to joint pain.
- **Infections:** Certain infections, such as viral or bacterial infections, can cause joint pain without significant joint inflammation.
- **Systemic illnesses:** Some systemic conditions, like fibromyalgia or systemic lupus erythematosus, may cause widespread joint pain without evident joint inflammation.

It is important to note that arthralgia can sometimes precede the development of arthritis, where joint pain without inflammation later progresses to joint inflammation and swelling.

In summary, arthritis refers to joint inflammation with pain, swelling, and stiffness, and can be caused by various conditions, while arthralgia refers to joint pain without significant inflammation and can be caused by factors such as injury, overuse, or underlying medical conditions. Diagnosis and appropriate management depend on a careful evaluation of symptoms, physical examination, and sometimes additional diagnostic tests.

Q. IM7.14 Describe the appropriate diagnostic work up based on the etiology.

Rheumatological diagnostic tests should be interpreted in the appropriate clinical context **(Table 8.3)**.

- A complete blood count, urine analysis, renal and liver functions test may provide diagnostic clues.
- ANA can be positive in 5–10% of general population and may increase with age. Due to the high sensitivity, a negative result rules out systemic lupus erythematosus but due to lack of specificity, positive result should be analyzed with caution.
- HLA-B27 positivity with a positive family history is highly suggestive of ankylosing spondylitis. However, relying only on HLA-B27 reports may lead to overdiagnosis as it can be seen in 8% of caucasians.
- Rheumatoid factor lacks sensitivity and specificity; hence both positive and negative results should be interpreted cautiously. Not useful if the patient lacks other criteria for diagnosis.
- Synovial fluid analysis helpful in diagnosing septic and crystal induced arthritis (*Refer* **Table 8.9**).
- Diagnostic imaging is helpful in rheumatological disorders.

Q. IM7.7 Discriminate, describe and discuss distinguishing articular and periarticular complaints.

Q. IM7.9 Describe the common signs and symptoms of articular and periarticular diseases.

Articular Complaints

Articular complaints specifically refer to issues or pain originating within the joint itself. These complaints involve the structures that make up the joint, including the bones, cartilage, synovial membrane, and joint capsule. Articular complaints commonly manifest as **diffuse pain, swelling, stiffness, and limited range of motion in the affected joint**.

Evaluation and management of articular complaints involve assessing the joint itself, including physical examination, imaging studies (X-rays, MRI, etc.), and laboratory tests.

Periarticular Complaints

Periarticular complaints refer to pain or conditions affecting the structures surrounding the joint, rather than the joint itself. These complaints involve the tissues, such as muscles, tendons, ligaments, bursae, and nerves, that support and connect to

TABLE 8.3: Diagnostic investigations in rheumatic diseases.

Investigations	***Disease conditions***
Complete blood count	Inflammatory arthritides
Anemia	SLE, RA, IBD, human parvovirus infection B19 infection
Thrombocytopenia	SLE, parvovirus B19 infection
Thrombocytosis	Acute phase reactants, vasculitis, infection
Leukopenia	SLE, RA, Felty's syndrome, Sjögren's syndrome, human parvovirus B19 infection
Leukocytosis	RA, vasculitis, reactive arthritis, infection
Eosinophilia	SLE, RA, IBD, sarcoidosis, dermatomyositis, scleroderma, Churg-Strauss syndrome, PAN, eosinophilic fasciitis, cholesterol emboli
Chest radiograph	
Infiltrates or nodules	RA, sarcoidosis, Wegener's granulomatosis, Churg-Strauss syndrome
Serositis	SLE, RA
Upper lobe fibrosis	Ankylosing spondylitis
Diffuse fibrosis	RA, scleroderma, polymyositis
Rheumatoid factor	Healthy persons; RA, SLE, Sjögren's syndrome, sarcoidosis, reactive arthritis, PMR, polymyositis, psoriatic arthritis, endocarditis, chronic infections, cancer, chronic liver disease, nonrheumatic causes
Joint aspiration	
Culture	Infection
Crystals	Gout, pseudogout
White blood cell count	Inflammation: >2,000 per mm^3 Probable infection: >50,000 per mm^3
Inflammatory markers	
Elevated erythrocyte sedimentation rate or C-reactive protein	Infection, most inflammatory arthritides, advanced age, PMR, giant cell arteritis, cancer, anemia, pregnancy
Antinuclear antibody	Healthy persons; SLE, RA, scleroderma, Sjögren's syndrome, vasculitis, polymyositis, medications, many nonrheumatic causes
Hepatic transaminase	
Elevated aspartate transaminase or alanine transaminase	SLE, PAN, sarcoidosis, hemochromatosis, Sjögren's syndrome, infectious hepatitis, polymyositis
Urinalysis	
Hematuria	SLE, Wegener's granulomatosis, PAN
Proteinuria	SLE, Wegener's granulomatosis, amyloidosis
Elevated alkaline phosphatase	Bone metastases, Paget's disease, osteomalacia, PMR, ankylosing spondylitis, hyperparathyroidism
Electrocardiogram	
AV block	Lyme disease, neonatal lupus, ankylosing spondylitis
Anti-double stranded DNA antibody	SLE, especially lupus nephritis
Anti–SS-A (anti-Ro) and anti–SS-B (anti-La) Antibodies	Sjögren's syndrome, SLE; healthy persons
HLA-B27	Healthy persons; spondyloarthropathies, reactive arthritis
Elevated uric acid	Gout, psoriatic arthritis, Paget's disease; healthy persons
False-positive VDRL	SLE, anticardiolipin antibody syndrome
Cytoplasmic antineutrophil cytoplasmic autoantibody (c-ANCA)	Wegener's granulomatosis
Elevated creatinine	SLE, Wegener's granulomatosis, vasculitis
Elevated creatine kinase	Polymyositis, dermatomyositis, hypothyroidism
Elevated calcium	Hyperparathyroidism, cancer, sarcoidosis

(SLE: Systemic lupus erythematosus; RA: Rheumatoid arthritis; IBD: Inflammatory bowel disease; PAN: Polyarteritis nodosa; PMR: Polymyalgia rheumatica)

the joint. Periarticular complaints typically cause **localized pain and tenderness around the joint**, **which may worsen with movement or specific activities**. Examples of periarticular complaints include:

- **Tendinitis**: Inflammation or irritation of a tendon, often caused by repetitive use or overuse of the joint.
- **Bursitis**: Inflammation of the fluid-filled sacs (bursae) that cushion the joints, resulting in pain and swelling.
- **Ligament sprains**: Stretching or tearing of ligaments that stabilize the joint, leading to pain, instability, and swelling.

- **Periarticular muscle strains**: Injuries to the muscles surrounding the joint, causing pain and limited range of motion.
  Assessment of periarticular complaints involves examining the structures surrounding the joint, evaluating range of motion, and conducting specific tests to identify the involved tissues.
  Differentiating between articular and periarticular complaints is important for accurate diagnosis and targeted treatment. However, its worth noting that sometimes both articular and periarticular structures can be involved simultaneously.

Articular Diseases

- **Joint pain:** Pain within the joint itself is a hallmark symptom of articular diseases. It can vary in intensity, duration, and location depending on the specific condition.
- **Joint swelling**: Inflammation within the joint often leads to swelling, which can cause visible enlargement or a feeling of fullness.
- **Joint stiffness**: Articular diseases commonly cause joint stiffness, especially after periods of rest or inactivity. Stiffness may improve with movement and activity.
- **Limited range of motion**: The affected joint may have reduced flexibility and limited ability to perform normal movements.
- **Joint warmth**: Inflammatory processes in the joint can lead to increased temperature and warmth around the affected area.
- **Joint deformity**: Over time, some articular diseases can result in joint deformities, such as joint malalignment or visible changes in joint structure.
- **Systemic symptoms**: In certain articular diseases like RA or SLE, individuals may experience systemic symptoms such as fatigue, fever, weight loss, or general malaise.

Periarticular Diseases

- **Tenderness:** Periarticular conditions often present with tenderness or **localized pain** around the joint. The affected area may be sensitive to touch or pressure.
- **Swelling:** Inflammation of periarticular structures, such as tendons or bursae, can lead to localized swelling adjacent to the joint.
- **Pain with movement:** Periarticular diseases may cause pain that worsens with specific movements or activities involving the affected joint.
- **Limited range of motion:** Similar to articular diseases, periarticular conditions can also result in reduced joint mobility and limited range of motion.
- **Muscle weakness:** Periarticular disorders can cause associated muscle weakness or loss of strength in the muscles around the affected joint.
- **Localized redness or warmth:** Inflammatory processes in periarticular tissues may lead to localized redness or increased warmth in the surrounding area.

Articular versus Periarticular

Features	***Articular***	***Periarticular***
Anatomical structure	Bone, synovium, cartilage, and capsule	Tendon, bursa, ligament, muscle
Painful site	Diffuse, deep	Localized
Pain on movement	Active/passive in all planes	Active in few planes
Swelling	Common	Uncommon

Q. IM7.10 Describe the systemic manifestations of rheumatologic diseases.

Rheumatological diseases primarily affect the joints and connective tissues but can also involve other organ systems in the body. Many diseases have systemic manifestations, meaning they can affect multiple organs or systems throughout the body. Here are some common systemic manifestations seen in rheumatic diseases:

- **Fatigue**: Fatigue is a prevalent symptom in many rheumatic diseases. It is often described as an overwhelming and persistent feeling of exhaustion that is not relieved by rest.
- **Fever**: Systemic rheumatic diseases, such as SLE or RA, can cause fever. Fever is typically episodic and may be associated with disease flares or inflammation.
- **Weight loss**: Unexplained weight loss can occur in some rheumatic diseases, particularly in systemic autoimmune conditions like SLE or vasculitis. It is often associated with disease activity and systemic inflammation.

- **Skin manifestations**: Rheumatic diseases can affect the skin in various ways. This may include rashes, photosensitivity (increased sensitivity to sunlight), ulcers, or discoloration. For example, SLE commonly presents with a butterfly-shaped rash on the face, and dermatomyositis can cause a characteristic rash on the eyelids and knuckles.
- **Raynaud's phenomenon:** Raynaud's phenomenon is characterized by episodic color changes (pallor, cyanosis, or redness) in the fingers and toes in response to cold or stress. It is commonly associated with systemic sclerosis (scleroderma) and other autoimmune conditions.
- **Respiratory involvement**: Certain rheumatic diseases, such as rheumatoid arthritis or systemic sclerosis, can affect the lungs. This may manifest as shortness of breath, cough, or interstitial lung disease.
- **Cardiac manifestations**: Rheumatic diseases can affect the heart and blood vessels. Examples include pericarditis (inflammation of the membrane surrounding the heart), myocarditis (inflammation of the heart muscle), or heart valve involvement. These can lead to symptoms like chest pain, palpitations, or shortness of breath.
- **Kidney involvement**: Some rheumatic diseases, including lupus nephritis, vasculitis, or certain forms of arthritis, can affect the kidneys. This can result in kidney inflammation, proteinuria (presence of excess protein in urine), and impaired kidney function.
- **Neurological manifestations**: Rheumatic diseases can involve the nervous system and cause symptoms such as peripheral neuropathy, cognitive dysfunction, seizures, or neuropathic pain.
- **Gastrointestinal symptoms**: Inflammatory bowel disease (IBD), such as Crohn's disease or ulcerative colitis, can be associated with certain rheumatic diseases, particularly seronegative spondyloarthropathies. This may lead to symptoms like abdominal pain, diarrhea, or rectal bleeding.

Rheumatoid Factor (RF)

Q. IM7.15 Write short note on rheumatoid factor and mention its significance.

Rheumatoid factor is an autoantibody (IgM, IgG and IgA) directed against the Fc fragment of human immunoglobulin G (IgG).

Significance

- RF has poor specificity and is positive in 70 to 80% of patients with rheumatoid arthritis (RA). It is appropriate and helpful only in patients suspected of having RA. It is not helpful in cases of low clinical suspicion.
- **High RF** titers are observed **with more severe disease** and **extra-articular disease**. The titers generally correlate with severity of disease. However, RF titers are not useful in assessing disease progression.
- It can **also be positive in many other conditions (Table 8.4)**.
- 10–30% of patients with long-standing RA are seronegative.
- **Seronegative RA** is RF-negative and ACPA-negative. These patients have a positive ANA (without antibodies against any specific antigen). In general, RA patients who are seronegative have a better prognosis, fewer extra-articular manifestations, and better survival.

TABLE 8.4: Conditions associated with a positive rheumatoid factor.

Autoimmune rheumatic diseases (%)	*Other conditions*
➢ Rheumatoid arthritis (RA) with nodules and extra-articular manifestations (100) ➢ Rheumatoid arthritis (overall 70) ➢ Sjögren's syndrome (75–95) ➢ Systemic lupus erythematosus (SLE) (15–35) ➢ Systemic sclerosis (20–30) ➢ Mixed essential cryoglobulinemia (40-100) ➢ Polymyositis/dermatomyositis (5–10) ➢ Polyarteritis nodosa (PAN) ➢ ANCA associated vasculitis ➢ Juvenile idiopathic arthritis ➢ Mixed connective tissue disease (50–60)	➢ **Chronic infections:** Infective endocarditis, tuberculosis, leprosy, syphilis ➢ **Viral infections:** Hepatitis, infectious mononucleosis ➢ **Hyperglobulinemia:** Chronic liver disease, sarcoidosis ➢ Interstitial lung disease, silicosis, asbestosis ➢ Primary biliary cholangitis ➢ **Normal population** – Age >65 years – Relatives of people with RA ➢ B-cell neoplasms

Anticyclic Citrullinated Peptide Antibodies (Anti-CCPs, ACPA)

Q. Enumerate the significance and indications for anticitrullinated peptide antibody (Anti-CCP).

Citrullinated Peptide Antigens

- These include fibrinogen, type II collagen, alpha enolase and vimentin.
- CCPs are derived from proteins in which arginine residues are converted to citrulline residues by an enzyme peptidyl arginine (which is abundant in inflamed synovium and in a variety of mucosal structures) during a variety of biological processes.

Anticyclic Citrullinated Peptide Antibodies (ACPA)

- These antibodies are **useful for diagnosis of RF** and may be involved in tissue injury. Many patients (about 70%) of RF have antibodies against cyclic citrullinated peptides (CCPs).
- These antibodies have **much high specificity** (93–98%) but **less sensitive** (60%) for diagnosis of RA.

- Anti-CCPs may be **detected even in asymptomatic patients** several years before the development of RA and are **associated with severe disease**. Thus, anti-CCP positive patients may require aggressive treatment.
- Antibodies against CCPs (anti-CCPs) from immune complexes and deposit in various tissues mainly being the joints.
- Positive results can occur in several autoimmune rheumatic diseases (SLE, Sjogren), tuberculosis, hepatis C infection, and chronic lung diseases.
- Antibodies to mutated citrullinated vimentin (**anti-MCV**) is associated with more severe disease than anti-CCP antibodies.
- Serum **14-3-3e**, which is an intracellular chaperonin protein, has been used diagnostically in RA.

Autoantibodies in Various Connective Tissue Diseases (CTD) (Table 8.5)

Q. Enlist the various antibodies seen in patients with connective tissue diseases and mention its significance.

TABLE 8.5: Autoantibodies in various connective tissue diseases.

Autoantibodies	***Importance***
Rheumatoid factor	*Refer* **Table 8.4**
Anticyclic citrullinated peptide	*Refer* above
Antinuclear antibodies (ANA)	*Refer* **Table 8.6**
Anti-double-stranded DNA (anti- dsDNA)	➢ **Highly specific for SLE**, positive in about 60% cases, positivity correlates with lupus nephritis ➢ Low titers are seen in Sjögren's syndrome, RA (rheumatoid arthritis) ➢ Levels often correlate with disease activity ➢ Usually absent in drug-induced SLE
Antihistone	➢ Sensitive for **drug-induced lupus** but not specific ➢ Useful in patients with a positive ANA ➢ Specific for SLE but positive in only 20–30% of cases
Anti-Smith (anti-Sm)	Positive in 20–30% cases of SLE. **Highly specific** for SLE
Anti-U1 ribonucleoproteins (RNP)	High titers in syndromes with features of polymyositits, lupus, scleroderma and mixed CTD (connective tissue disease)
Anti-Ro (anti-SS-A)	➢ Positive in **Sjögren's syndrome** with extraglandular features ➢ Positive in 40% cases of SLE and is associated with photosensitive rash and pulmonary disease. May be positive in ANA-negative lupus. Indicates higher risk of lupus nephritis ➢ May be positive in neonatal lupus or congenital heart block due to maternal antibodies
Anti-La (anti-SS-B)	➢ Present in 10–15% cases of SLE and indicates low-risk of nephritis ➢ Associated with Sjögren's syndrome
Antiphospholipid	➢ Diagnosis of APLAs. Present in nearly 50% cases of SLE ➢ Three types: Lupus anticoagulant (LA), anticardiolipin (aCL) and anti-β_2-glycoprotein-I (anti-β2-GPI) antibody
Anticentromere	➢ Systemic sclerosis (20–35% cases) ➢ CREST syndrome (calcinosis, Raynaud's phenomenon, esophageal dysfunction, sclerodactyly and telangiectasia) ➢ Primary biliary cirrhosis
Antitopoisomerase I (anti-scl-70)	Highly specific for systemic sclerosis, found in 20–40% cases of systemic sclerosis and associated with diffuse cutaneous, pulmonary and cardiac involvements
Anti-jo1	Present in 30% cases with polymyositis or dermatomyositis Associated with Raynaud's phenomenon
Antineutrophil cytoplasmic antibodies (ANCA)	Refer below

Antinuclear Antibodies

Q. Enumerate the indications, significance and staining patterns of antinuclear antibodies.

Antinuclear antibodies (ANA) are **directed against one or more components of the cell nucleus**. The component of the nucleus includes DNA, RNA, proteins as well as complexes of proteins with nucleic acid.

Significance

- **High titers** of ANA (>1:160) are of **more diagnostic** significance than low titers.
- Circulating **levels of ANA do not correlate with severity or activity** of the disease.
- ANA is **positive in several conditions (Table 8.6)**.

TABLE 8.6: Conditions associated with a positive ANA test.

Diseases where ANA is useful in diagnosis	***Diseases where ANA is not useful in diagnosis***
➢ Systemic lupus erythematosus (95–100%) ➢ Systemic sclerosis (60–80%) ➢ Sjögren's syndrome (40–80%) ➢ Drug-induced lupus (>95%) ➢ Mixed connective tissue disease (100%) ➢ Polymyositis/dermatomyositis (30–80%) ➢ Autoimmune hepatitis (100%)	➢ Rheumatoid arthritis (30–50%) ➢ Autoimmune thyroid disease (30–50%) ➢ Malignancy varies widely ➢ Infectious diseases varies widely

Note: About 5% of healthy individuals have an ANA titer >1:80.

- ANA is used as a **screening test for systemic lupus erythematosus (SLE) and systemic sclerosis (SSc).** ANA has high sensitivity for SLE (100%) but low specificity (10–40%). A negative ANA almost rules out SLE but a positive result does not confirm it. It should not be used to monitor the course of SLE or other diseases.

Tests for detection: ANAs are detected by indirect immunofluorescent staining **(Table 8.7)** of fresh-frozen sections of rat liver or kidney or Hep-2 cell lines (a line of human epithelial cells).

TABLE 8.7: Pattern of antinuclear antibody staining.

Pattern of staining	*Diagrammatic appearance*	*Staining pattern due to*	*Associated conditions*
Homogeneous or diffuse staining of the entire nucleus with or without apparent masking of the nucleoli		Antibodies to nucleosomes (anti-DNP), histones (anti-histone) and occasionally double-stranded DNA (anti-dsDNA)	Rheumatoid arthritis, systemic lupus erythematosus (SLE) and miscellaneous disorders (anti- ssDNA)
Rim or peripheral staining		Antibodies to double-stranded DNA (anti-DNA) and sometimes to nuclear envelope proteins. Not seen on HEp-2	SLE
Speckled (may be coarse or fine) pattern—the presence of uniform or variable-sized speckles throughout the nucleus. Most common pattern and is least specific		Antibodies to non-DNA nuclear constituents such as Sm antigen (anti-Sm), ribonucleoprotein (anti-RNP), and SS-A (anti-SS-A) and SS-B reactive antigens (anti-SS-B)	SLE, systemic sclerosis (SS), polymyositis (PM)/ dermatomyositis (DM)
Nucleolar pattern—presence of a few discrete spots within the nucleus-stains nucleoli within the nucleus, sharply separated from the unstained nucleoplasm		Antibodies to RNA (anti-nucleolar)	Most often seen in systemic sclerosis
Centromeric pattern—discrete uniform speckles throughout the nucleus. The number of speckles corresponds to a multiple of the normal chromosome number		Antibodies specific for centromeres (anti-centromere)	Systemic sclerosis, Sjögren syndrome, and other diseases

(ds: Double stranded; ss: Single stranded)

Extractable Nuclear Antibodies

Q. Write short essay/note on extractable nuclear antibodies.

- These are antibodies to extractable nuclear antigens (ENA) and are directed against small ribonuclear proteins (RNA).
- **Types of antibodies and associated conditions are listed in Table 8.8.**
- Their sensitivity and specificity are poor. Though used for diagnostic confirmation, they do not exclude a specific CTD.
- They do not correlate with disease activity and may be found in patients without active disease.

TABLE 8.8: Types of antibodies and associated conditions.

Type of extractable nuclear antibody	*Associated conditions*
Anti-Sm	Only in SLE and represent a serologic marker in disease classification. They are associated with renal involvement
Antiuracil-rich 1 ribonucleoprotein (U1RNP)	SLE and in mixed connective tissue disease
Anti-SS-A/Ro and anti-SS-B/La	SLE and in Sjögren's syndrome
Anti-tRNA synthetases	Polymyositis/dermatomyositis
Antitopoisomerase-1 antibodies (Scl-70)	Diffuse systemic sclerosis
Anticentromere antibodies	Limited systemic sclerosis

Antineutrophil Cytoplasmic Antibodies

Q. Write short essay/note on antineutrophil cytoplasmic antibodies (ANCA), their significance/ANCA associated disorders.

Antineutrophil cytoplasmic antibodies (ANCAs) are heterogeneous group of IgG **autoantibodies directed against certain proteins** (mainly enzymes) **in the cytoplasmic granules of neutrophils and** lysosomes of **monocytes**.

Patterns: On the basis of the target antigens and pattern of immunofluorescence staining, two common patterns of ANCA have been distinguished.

1. **Anti-proteinase-3 (PR3-ANCA):** It is also called cytoplasmic or cANCA. PR3 is a constituent of neutrophil azurophilic granule. It shares homology with many microbial peptides and antibodies against microbial peptides. Antibodies against proteinase-3 (PR3) form PR3-ANCAs. They produce cytoplasmic fluorescence (**cANCA**). They are associated with **Wegener's granulomatosis.**
2. **Anti-myeloperoxidase (MPO-ANCA):** It is also called perinuclear or pANCA. MPO is a lysosomal enzyme normally involved in producing oxygen-free radicals. Antibodies to myeloperoxidase (MPO) forms MPO-ANCAs which produces perinuclear fluorescence (**pANCA**). It can be induced by drugs (e.g. propylthiouracil). They are associated with **microscopic polyangiitis and Churg-Strauss syndrome**.

Significance

- ANCA are **strongly associated with small-vessel vasculitis** and are useful in the diagnosis and monitoring of systemic vasculitis. For their significance in vasculitis, ANCA should be assayed both with indirect immunofluroscence (screening test) and direct ELISA for proteinase-3 or myeloperoxidase.
- **ANCA are not specific for vasculitis**. They may be positive in autoimmune liver disease, malignancy, infection [bacterial and human immunodeficiency virus (HIV)], inflammatory bowel disease, chronic hepatitis, primary sclerosing cholangitis, Felty's syndrome, rheumatoid arthritis, SLE and pulmonary fibrosis.

Synovial Fluid in Disease States (Table 8.9)

Q. Differentiate the synovial fluid features in various arthritis.

Q. IM7.16 Enumerate the indications for arthrocentesis.

- Arthrocentesis helps in the diagnosis of septic/infective arthritis and crystal arthropathies and the indications are as below.
    - Monoarthritis (acute or chronic)
    - Monoarthritis in a patient with chronic polyarthritis
    - Suspicion of joint infection
    - Crystal-induced arthritis
    - Hemarthrosis or trauma with joint effusion.
- Hemorrrhagic effusion may suggest trauma or mechanical derangement, coagulopathy or others.
- Counts less than 2,000 per mm^3 may suggest noninflammatory causes like osteoarthritis or trauma.

TABLE 8.9: Features of synovial fluid in various disease states.

	Normal	*Noninflammatory*	*Inflammatory*	*Pyogenic*
Appearance	Clear	Clear	Cloudy, yellow	Turbid
Viscosity	High	High	Low	Variable, infection usually low
Mucus clot	Good	Good	Poor	Poor
Total WBC/mm^3	<200	200–5000	5000–50,000	>50,000
Predominant cell	Monocytes	Monocytes	Polymorphs >60%	Polymorphs >80%. Bacteria present
Protein	<2–3 g/dL	<2–3 g/dL	>3 g/dL	>3 g/dL
Sugar	Equal to blood sugar (BS) taken simultaneously	Equal to blood sugar (BS)	25–50% less than blood sugar	>50% less than blood sugar

- WBC count of at least 2,000 per mm^3 in synovial fluid suggests inflammation, whereas a count higher than 50,000 per mm^3 indicates infection. In later cases, synovial fluid needs to be cultured for ruling out infection.
- Crystal identification by polarized microscopy useful for diagnosis of gout and pseudogout.

Q. IM7.17 Describe the role of diagnostic imaging in rheumatological disorders.

Currently available modalities include conventional radiography, computed tomography (CT), magnetic resonance imaging (MRI), arthrography, nuclear medicine scans (bone scintigraphy), and ultrasound.

- Conventional X-ray findings can vary depending on the specific rheumatological condition. Here are some common rheumatological conditions and their associated X-ray findings:
  - **Rheumatoid arthritis (RA):**
    - **Joint erosions**: X-rays may show erosions at the joint margins, particularly in the hands and feet.
    - **Joint space narrowing**: Progressive joint damage can result in narrowing of the joint space.
    - **Periarticular osteopenia**: Decreased bone density around the affected joints.
    - **Joint deformities**: X-rays may reveal joint deformities such as ulnar deviation of the fingers or swan-neck and boutonniere deformities.
  - **Ankylosing spondylitis (AS):**
    - **Sacroiliitis**: X-rays of the sacroiliac joints may reveal signs of inflammation, such as erosions, sclerosis, or new bone formation (syndesmophytes).
    - **Bamboo spine**: Progressive fusion of the vertebrae can lead to a characteristic appearance on X-rays, resembling a bamboo stalk.
    - **Squaring of vertebral bodies**: Involvement of the spine may result in the squaring of the vertebral bodies, especially in the thoracic spine.
  - **Psoriatic srthritis (PsA):**
    - **Destructive joint changes**: X-rays may show erosions, joint space narrowing, and periarticular osteopenia similar to those seen in RA.
    - **Enthesitis**: X-rays may reveal signs of enthesitis, such as entheseal erosions or new bone formation at sites where tendons or ligaments attach to bone.
    - **Dactylitis**: X-rays may show swelling of an entire finger or toe, known as "sausage digit," due to inflammation involving both joints and soft tissues.
  - **Systemic lupus erythematosus (SLE):**
    - **Periarticular soft tissue swelling**: X-rays may demonstrate soft tissue swelling around the joints.
    - **Joint erosions**: In severe cases, erosions may be observed, particularly in the hands and wrists.
  - **Osteoporosis**: X-rays may reveal decreased bone density in patients with SLE-related osteoporosis.
  - **Gout:**
    - **Presence of tophi**: X-rays may show the deposition of urate crystals in and around the joints, forming nodular masses known as tophi.
    - **Joint erosions**: In advanced stages of gout, X-rays may reveal erosions or joint destruction, particularly in the feet and hands.
  - **Chest radiographs** may reveal underlying systemic disease. Radiographs showing infiltrates or nodules are suggestive of rheumatoid arthritis, sarcoidosis, Wegener's granulomatosis or microscopic polyangiitis. Serositis on radiograph suggests RA or SLE. Ankylosing spondylitis may present with upper lobe fibrosis whereas RA, scleroderma and polymyositis may present with diffuse fibrosis.
- **Magnetic resonance imaging** is sensitive for diagnosing soft tissue injuries. MRI done in the early course of RA may reveal cartilage destruction that may not be picked up in routine radiographs. MRI can also be used to demonstrate tophi, synovial changes and erosions.
- **Ultrasound** is useful in the detection of soft tissue abnormalities such as tendinitis, tenosynovitis, bursitis, enthesitis and entrapment neuropathies.
- **CT** is useful in the diagnosis of low back pain syndromes. Also HRCT lung can help diagnosis of ILD.
- **Nuclear medicine scans** have great sensitivity for detecting many disease processes because they image and quantify physiologic biochemical processes, as well as provide anatomic information. The combination with single photon emission computer tomography (SPECT) increases anatomical resolution. Whole-body bone scintigraphy might also

help differentiate inflammatory spondyloarthropathies from other inflammatory disorders such as SAPHO (synovitis, acne, pustulosis, hyperostosis, osteitis).

RHEUMATOID ARTHRITIS

Q. Discuss the etiology, pathogenesis, clinical manifestations, diagnosis, investigations, complication, and management of rheumatoid arthritis.

Rheumatoid arthritis (RA) is the most common form of chronic inflammatory, potentially crippling arthritis with multisystem involvement affecting approximately 1% of the adult population.

Etiology

The cause is multifactorial and genetic, epigenetic and environmental factors play a part in the pathogenesis of RA.

- **Genetic factors:** Genetic susceptibility is a **major factor** in the pathogenesis of rheumatoid arthritis.
  - **HLA genes:** RA is linked to specific **HLA-DRB1 locus**.
  - **Non-HLA genes:** Polymorphism in *PTPN22* gene, which encodes a tyrosine phosphatase.
  - Abnormal DNA methylation, histone modifications, and microRNA regulation play a key role.
- **Environmental arthritogenic agents:** They are thought to **initiate the disease** process. **Smoking** and several **microbial agents** (e.g. virus, mycobacteria porphyromonas gingivalis, and *Mycoplasma)* have been suggested but not proved.
- **Autoimmunity:** The initial inflammatory synovitis, an autoimmune reaction with T cells is responsible for the chronic destructive nature of rheumatoid arthritis.

Pathogenesis

The rheumatoid synovium (**Pannus**) behaves like a locally-invasive tumor. A cascade network of cytokines like granulocyte macrophage colony-stimulating factor (GM-CSF), interleukin (IL)-2, IL-15, IL-13, IL-17, IL-18, interferon-gamma (IFN-gamma), tumor necrosis factor (TNF) and transforming growth factor-beta (TGF-beta) are involved in the disease progression. B cells, CD4$^+$ T cells, compliment mediated immune activation play a contributory role.

Clinical Features

Q. Enumerate the clinical features of rheumatoid arthritis.

- **Gender:** Female to male ratio is 3:1.
- **Age:** Most common age of onset is between 30 and 50 years, but the disease can occur at any age. In women in late childbearing years and in men during sixth to eighth decade.

Onset

The presenting symptoms result from inflammation of the joints, tendons, and bursae. The onset varies:

- **Slow and insidious in onset:** Presents with malaise, fatigue, anorexia, weakness and generalized musculoskeletal pain.
- **Acute onset:** Sometimes RA may be very acute in onset, with morning stiffness, polyarthritis and pitting edema. This type occurs more commonly in old age.
- **Palindromic onset:** Occasionally, patient present with relapsing and remitting episodes of pain, stiffness and swelling that last for only a few hours or days alternating with symptom-free periods.
- **Systemic onset/extra-articular involvement:** Nonarticular symptoms, which will antedate the onset of arthritis
- **Arthritis robustus**: Typically seen in men. Patients have bulky, proliferative synovitis causing joint erosions and deformities, but the patient experiences little pain or disability.
- **Rheumatoid nodulosis:** Patients with recurrent pain/swelling in different joints, subcutaneous nodules, and subchondral bone cysts on radiographs.
- Rarely, onset may be monoarticular.

Articular Manifestations

Q. Describe the articular manifestations of rheumatoid arthritis.

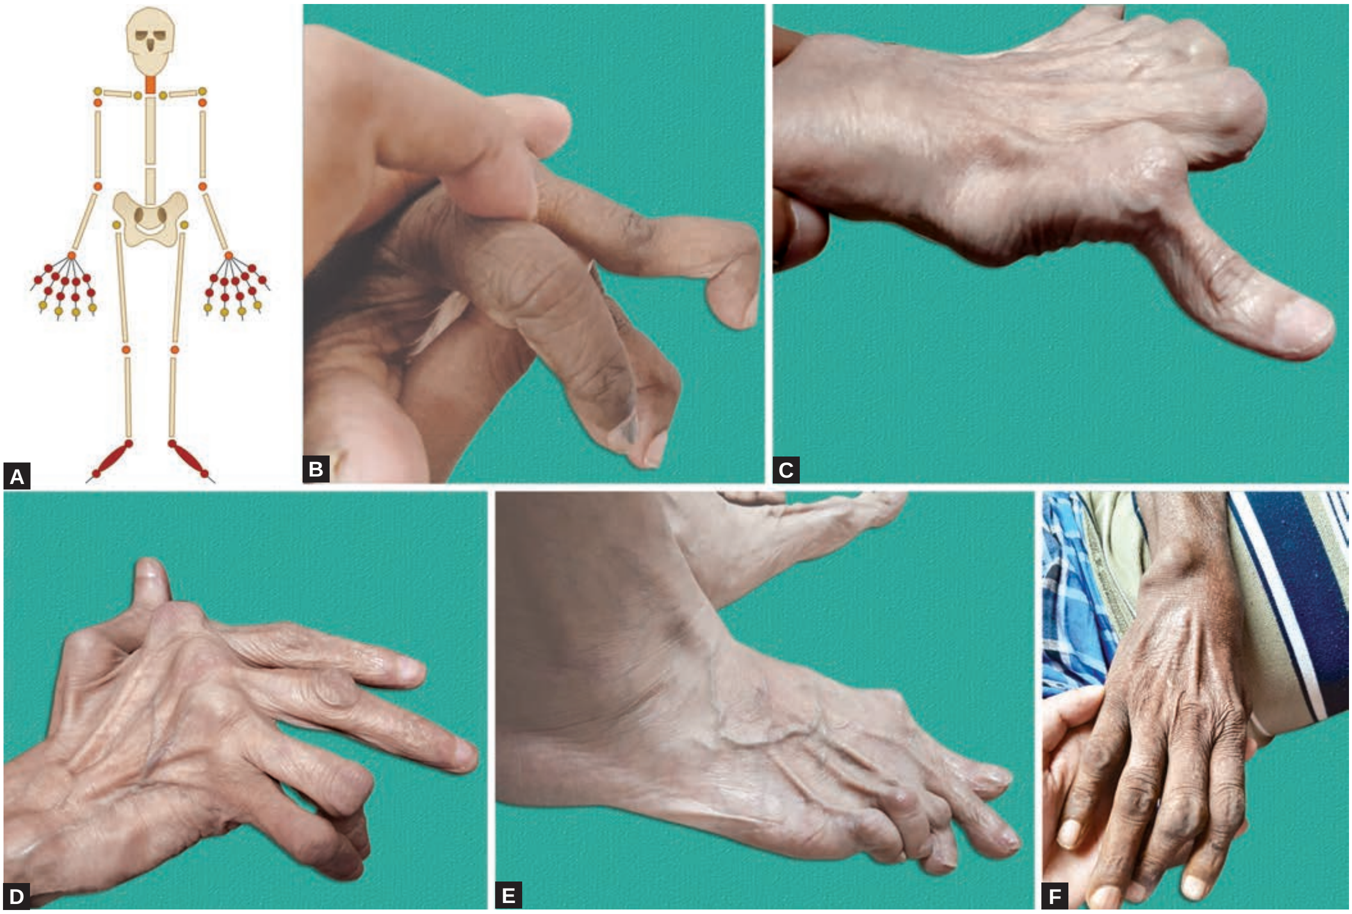
- **Joints involved (Fig. 8.1A):** RA can affect any of the synovial (diarthrodial) joints and involvement is usually in a **symmetric distribution**. Most commonly, RA starts in the small joints, namely metacarpophalangeal (MCP), proximal interphalangeal (PIP), and metatarsophalangeal (MTP) joints, followed by the involvement of large joints (wrists, knees, elbows, ankles, hips, and shoulders). Pitting edema over the dorsum gives rise to the **"boxing glove"** appearance. In RA, the hypertrophied synovium (also called pannus) invades and erodes contiguous cartilage, ligaments and bone.

- **Symptoms:** These include pain, swelling, and stiffness. Stiffness dominating in the mornings ('morning stiffness') lasting more than 1 hour is characteristic. Routine activities early in the morning like brushing teeth and combing hair may be very difficult.

Q. Write short note on rheumatoid hand.

Hand and wrist (Figs. 8.1B and C): Hands are a major site of involvement and produces significant disability.

- **The DIP joint is characteristically always spared** unless the patient also has osteoarthritis (both coexist, particularly in elderly patients).
- **Spindling of the fingers:** It is the earliest finding characterized by swelling of the proximal, but not the distal interphalangeal joints.
- **Deformities:** Destruction of the joints and soft tissues may lead to chronic, irreversible deformities.
    - **Ulnar deviation (Figs. 8.1B and C):** It results from subluxation of the metacarpophalangeal (MCP) joints, with subluxation of the proximal phalanx to the volar side of the hand.
    - **'Swan-neck' deformity (Figs. 8.1B and C):** It is due to hyperextension of the proximal interphalangeal joints (PIP) with flexion of the distal interphalangeal joints (DIP). At DIP joint there is elongation or rupture of attachment of the extensor tendon to the base of the distal phalanx; this results in mallet deformity of distal joint and in addition, an extensor tendon imbalance, leading to hyperextension deformity at PIP joint.



FIGS. 8.1A TO F: Rheumatoid arthritis. (A) Pattern of joint involvement; (B) Swan neck deformity; (C) Boutonniere deformity; (D) Z deformity and ulnar deviation; (E) Hammer toes and hallux valgus; (F) Bow string sign.

  - **'Boutonniere' or 'button-hole' deformity (Fig. 8.1C):** This deformity is due to flexion of the proximal interphalangeal (PIP) joints and extension of the distal interphalangeal (DIP) joints. Disruption of the central slip of the extensor tendon and the triangular ligament allows each of the conjoint lateral bands of the digit to slide volarly resulting in a pathologic flexion force and an extension lag; all tendons traversing the PIP joint in this setting elicit flexion of the joint.
  - **'Gamekeepers thumb':** It is the result of hyperextension of the first interphalangeal joint and flexion of the first metacarpophalangeal joint. This leads to loss of thumb mobility and occurrence of pinch.
  - **Hitchhiker's thumb** (Z-shaped deformity) in which the thumb flexes at the metacarpophalangeal joint and hyperextends at the interphalangeal joint.
  - Inflammation of the carpometacarpal joint leads to volar subluxation during contracture of the adductor hallucis.
  - **'Z' deformity (Fig. 8.1D):** It is due to radial deviation of the wrist, ulnar deviation of the digits with palmar subluxation of the first MCP joint with hyperextension of the first interphalangeal (IP) joint.
  - **Carpal tunnel syndrome:** Due to synovial proliferation in and around the wrists producing compression of the median nerve.
  - The **"bow string" sign (Fig. 8.1F)** (prominence of the tendons in the extensor compartment of the hand).
- **Feet and ankle:** In most patients, feet (particularly the MTP joints) are involved early.
- **'Broadening' of the forefoot:** Due to swelling of the metatarsophalangeal joints.
- **Subluxation of the toes at the MTP joints ("cock-up" deformities):** Leads to skin ulceration on the top of the toes and painful ambulation because of loss of the cushioning pads which protect the metatarsals heads.
- **Hallux valgus deformity** and **hammer toes** may be seen **(Fig. 8.1E)**.

Larger joints

- **Involvement of large joints (knees, ankles, elbows, hips and shoulders)** is common but generally occurs somewhat later than small joint involvement.
- Shoulder joint involvement may present as glenohumeral arthritis, rotator cuff fraying and rupture.
- **Synovial cysts:** They present as fluctuant masses around involved joints (large or small). Best examples of synovial cyst is **popliteal ('Baker's) cysts** which develops in the knee joint. The knee synovitis produces excess synovial fluid that communicates posteriorly with the cyst (between the knee joint and the popliteal space) but is prevented from returning to the joint by a one-way valve-like mechanism. Ruptured Baker's cysts can resemble a deep vein thrombosis.

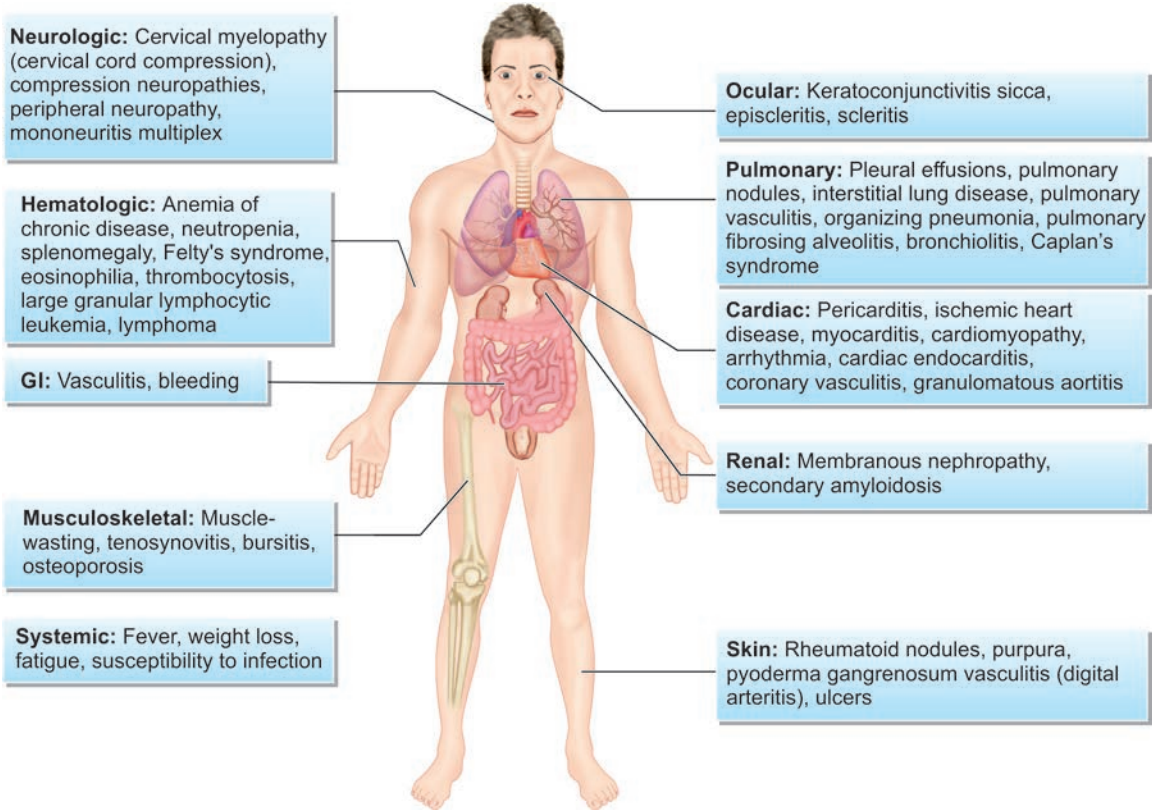
Other joints

- **Axial skeleton:** Although most of the spine is spared in RA, the **cervical spine** (atlantoaxial subluxation) can be involved producing quadriparesis.
- **Cricoarytenoid joint** involvement may present (30%) with hoarseness of voice and inspiratory stridor.

Extra-articular Manifestations (Fig. 8.2)

Q. Describe the various systemic manifestations of rheumatoid arthritis.

- **Patients who are RF- or ACPA-positive (dual-positivity may pose a higher risk), HLA-DR4-positive, and males are more likely to have extra-articular manifestations.**
- **Constitutional:** RA is a systemic disease and features such as fatigue, weight loss, and low-grade fever (<38°C) occur frequently. Systemic features are more common in patients who have RF or ACPA antibodies, or both.
- **Rheumatoid nodules**
  - Rheumatoid nodules are usually **subcutaneous** and are typically benign.
  - **Significance:** Nodules are seen in about one-fourth of patients with RA and, almost exclusively in those patients who are seropositive for rheumatoid factor. They are clinical predictors of more severe arthritis, seropositivity, joint erosions and rheumatoid vasculitis.
  - **Sites:** Typically occur on extensor surfaces, over joints or on areas subject to repeated trauma (particularly forearms sacral prominences, scalp and the Achilles tendon). Rarely, they develop in lungs, pleura, heart, pericardium or in the sclera of the eye.
  - **Characteristics:** On examination, rheumatoid nodules are 2 mm to 5 cm in size, firm and nontender (unless traumatized). They have a characteristic histologic picture (central area of fibrinoid material surrounded by a palisade of proliferating mononuclear cells), and are thought to be triggered by small vessel vasculitis.
  - Methotrexate therapy can trigger a syndrome of increased nodulosis despite good control of the joint disease of RA.



Neurologic: Cervical myelopathy (cervical cord compression), compression neuropathies, peripheral neuropathy, mononeuritis multiplex
Hematologic: Anemia of chronic disease, neutropenia, splenomegaly, Felty's syndrome, eosinophilia, thrombocytosis, large granular lymphocytic leukemia, lymphoma
GI: Vasculitis, bleeding
Musculoskeletal: Muscle-wasting, tenosynovitis, bursitis, osteoporosis
Systemic: Fever, weight loss, fatigue, susceptibility to infection
Ocular: Keratoconjunctivitis sicca, episcleritis, scleritis
Pulmonary: Pleural effusions, pulmonary nodules, interstitial lung disease, pulmonary vasculitis, organizing pneumonia, pulmonary fibrosing alveolitis, bronchiolitis, Caplan's syndrome
Cardiac: Pericarditis, ischemic heart disease, myocarditis, cardiomyopathy, arrhythmia, cardiac endocarditis, coronary vasculitis, granulomatous aortitis
Renal: Membranous nephropathy, secondary amyloidosis
Skin: Rheumatoid nodules, purpura, pyoderma gangrenosum vasculitis (digital arteritis), ulcers

FIG. 8.2: Extra-articular manifestations of RA.

- **Rheumatoid vasculitis**
  - **RA-associated small vessel vasculitis:** It can manifest as digital infarcts, cutaneous ulcerations, palpable purpurae, distal gangrene and leukocytoclastic vasculitis. They require prompt more aggressive treatment with disease-modifying antirheumatic drugs (DMARDs).
  - **Other manifestations:** Polyneuropathy, mononeuritis multiplex and visceral infarction (resulting in stroke and acute myocardial infarction) and mesenteric arteritis. **Pyoderma gangrenosum** occurs with increased frequency with RA.
- **Dermatological manifestations**
  - Rheumatoid nodules
  - Skin ulcers
  - Neutrophilic dermatosis (Sweet syndrome), pyoderma gangerenosum
  - Skin atrophy, petechiae, Raynaud's phenomenon.

Pleuropulmonary Manifestations

Q. Enlist the pleuropulmonary manifestations of rheumatoid arthritis.

- **Pleural lesions: Pleural effusions (exudative)** occur more commonly in men and are usually small and asymptomatic. Pleural fluid is characterized by low glucose and pH.
- **Pulmonary lesions:**
  - **Rheumatoid nodules** especially in men; usually solid, but may calcify, cavitate or become infected.
  - **Diffuse interstitial fibrosis** causes dyspnea and may progress to cor pulmonale. ILD occurs commonly in RA patients but is symptomatic and progressive in <10%. In RA, the usual interstitial pneumonia (UIP) pattern of ILD is most common, whereas the nonspecific interstitial pneumonia (NSIP) pattern is common in other connective tissue disease associated-ILDs.
  - **Bronchiolitis obliterans** with or without organizing pneumonia.
  - **Granulomatous pneumonitis**.
  - **Pulmonary arteritis** (vasculitis) may result in infarction.

  - **Caplan's syndrome:** It is characterized by the coexistence of seropositive RA and rounded fibrotic, peripherally located nodules of 0.5–5 cm diameter in the lung along with coal worker's pneumoconiosis (CWP)/silicosis.
  - **Treatment induced:** Methotrexate induced lung fibrosis, immunosuppression related infections like TB.
- **Cardiac manifestations**
  - **Pericardial effusions** are common. Rarely, long-standing pericardial disease results in a fibrinous pericarditis and constrictive pericarditis.
  - Coronary artery disease due to **premature atherosclerosis**. Rarely, myocarditis, **valvular involvement** and **conduction defects**.
  - One of the leading causes of death in patients with RA; frequency is increased 1.5 to 2-fold over the general population.
- **Neurological manifestations**
  - **Peripheral nerve entrapment syndromes:** For example, carpal tunnel syndrome (median nerve at the wrist), and tarsal tunnel syndrome (anterior tibial nerve at the ankle).
  - **Myelopathy:** Due to spinal cord compression produced by acquired atlanto-axial dislocation.
  - **Mononeuritis multiplex:** Due to vasculitis.
- **Ophthalmological manifestations**
  - **Sjögren's syndrome/Sicca complex:** Comprising keratoconjunctivitis sicca, xerostomia and salivary (parotid) gland enlargement.
  - **Scleritis,** episcleritis may progress to perforation of the orbit (scleromalacia perforans).
  - **Brown's syndrome:** Diplopia due to tendinitis of the superior oblique muscles.
- **Osteoporosis:** Osteoporosis secondary to rheumatoid involvements is very common especially with corticosteroid therapy and immobilization.
- **Hematological manifestations**
  - **RBC:** Normocytic normochromic anemia. Causes of anemia in RA include anemia of chronic disease, anemia due to gastrointestinal bleed secondary to NSAIDs/steroids, methotrexate induced folate deficiency, marrow suppression due to disease/drugs and part of hypersplenism if splenomegaly present.
  - **WBC:** Eosinophilia and mild leukocytosis. Neutropenia in cases of Felty's syndrome and large granular lymphocyte syndrome. Patients with RA are at an **increased risk for infections,** and this risk is further increased by some therapies.
  - **Platelets:** Thrombocytosis.
  - **Felty's syndrome:** It is the triad of RA, splenomegaly, and neutropenia.
- **Renal involvement:** In the form of glomerulonephropathy, vasculitis, drug toxicities and secondary amyloidosis.
- **Malignancies:** RA patients have an increased risk of **lymphomas**.

Diagnosis

Q. Enumerate the ACR (American College of Rheumatology)/EULAR criteria for the diagnosis of rheumatoid arthritis.

- Diagnostic criteria of rheumatoid arthritis: In 2010, a collaborative effort between the American College of Rheumatology **(Box 8.1)** and the ACR/European League against Rheumatism presented the criteria for the diagnosis of RA **(Table 8.10)**.

Box 8.1: American College of Rheumatology (ACR) criteria for rheumatoid arthritis.

- Morning stiffness*
- Arthritis of 3 joint areas*
- Arthritis of the hands*
- Symmetric arthritis*
- Rheumatoid nodules
- Serum rheumatoid factor positive
- Radiographic changes

*These criteria must be present for more than 6 weeks. Presence of 4 criteria favors definite diagnosis of RA.

TABLE 8.10: American College of Rheumatology (ACR)/European League against Rheumatism (EULAR) classification criteria for rheumatoid arthritis, 2010.

Features	*Score*
A. Joint involvement	
➢ 1 large joint (shoulder, elbow, hip, knee, ankle)	0
➢ 2–10 large joints	1
➢ 1–3 small joints (MCP, PIP, thumb IP, MTP, wrists) + involvement of large joints	2
➢ 4–10 small joints + involvement of large joints	3
➢ >10 joints (at least 1 small joint)	5
B. Serology (at least one test result is needed for classification)	
➢ Negative RF and negative ACPA	0
➢ Low-positive RF or low-positive ACPA (≤3 times ULN)	2
➢ High-positive RF or high-positive ACPA (≥3 times ULN)	3
C. Acute-phase reactants (at least one test result is needed for classification)	
➢ Normal CRP and normal ESR	0
➢ Abnormal CRP or abnormal ESR	1
D. Duration of symptoms	
➢ <6 weeks	0
➢ ≥6 weeks	1

(MCP: Metacarpophalangeal joint; PIP: Proximal interphalangeal joint; IP: Interphalangeal joint; MTP: Metatarsophalangeal joint; RF: Rheumatoid factor; ACPA: Anticitrullinated protein antibodies; ULN: Upper limit of normal; CRP: C-reactive protein; ESR: Erythrocyte sedimentation rate)

- The Disease Activity Score in 28 joints **(DAS28)** is used to grade severity of RA.
- Simplified Disease Activity Index **(SDAI)** and Clinical Disease Activity Index **(CDAI)** are also used in monitoring.
- Above criteria yields a score of 0–10. **A score of ≥6 required for definitive diagnosis of RA**.
- A score of <6/10 are not classifiable as RA, but their status to be reassessed over time.
- **A clinician should consider a diagnosis other than RA particularly in patients who have an asymmetric arthritis, migrating pattern, predominantly large-joint arthritis, distal interphalangeal (DIP) joint involvement, rashes, back disease, renal disease, leukopenia, or hypocomplementemia.**

Investigations

Q. Discuss the diagnostic work up for rheumatoid arthritis.

- **Serology**
  - **Rheumatoid factor**
  - **Anticyclic citrullinated protein antibodies** (ACPA)
- **Markers of acute inflammation**
  - **Anemia of chronic disease** is seen in majority of patients, and the degree of anemia is proportional to the activity of the disease.
  - **Thrombocytosis** is common, and platelet counts return to normal as the inflammation is controlled.
  - **Acute phase reactants**, **erythrocyte sedimentation rate and C-reactive protein levels** parallel the activity of the disease, and their persistent elevation carries poor prognosis (joint destruction and mortality).
  - **WBC counts** may be raised, normal, or profoundly depressed (Felty's syndrome).
- **Other autoantibodies:** RA is associated with other autoantibodies, such as antinuclear antibodies (30% of patients) and antineutrophilic cytoplasmic antibodies, particularly of the perinuclear type (30% of patients).
- **Radiographs of the affected joints:** Radiological changes include symmetrical pattern of involvement, juxta-articular osteoporosis, soft tissue swelling, bone erosions and narrowing of the joint space.
  The mnemonic **ABCDE'S** is a convenient way to remember these:
  - **A:** Alignment, abnormal; no ankylosis
  - **B:** Bones—periarticular (juxta-articular) osteoporosis; no periostitis or osteophytes
  - **C:** Cartilage—uniform (symmetric) joint space loss in weight-bearing joints; no cartilage or soft tissue calcification
  - **D:** Deformities (swan neck, ulnar deviation, boutonnière) with symmetrical distribution
  - **E:** Erosions, marginal
  - **S:** Soft-tissue swelling; nodules without calcification.
- **Ultrasonography and MRI:** More sensitive than plain radiographs and detects soft-tissue synovitis before joint damage. *Doppler ultrasound* is useful for demonstration persistent synovitis when deciding on the need for DMARDs or assessing their efficacy.
- **Synovial fluid analysis:** White blood cell counts typically range from 5000–50,000 per microliter with approximately two-third of the cells being neutrophils with no crystals or organism. None of the synovial fluid findings are pathognomonic.
- **Testing for latent tuberculosis:** Before starting biological agents.

Q. Develop an appropriate treatment plan for patients with rheumatoid arthritis.

Q. Describe the various treatment options for rheumatoid arthritis.

Management

The early recognition of inflammatory arthritis, before irreversible injury has occurred, is the most important element in the effective management

General Measures

The goal of therapy is **disease remission** and **to maintain this remission** by continuing therapy.

- **Rest and splinting** of the involved joints during the acute stage.
- **Physiotherapy:** Helps in mobilization and prevention of contractures.
- **Smoking cessation, control of cardiovascular risks, screening for osteoporosis**

Medical Therapy

Three types of medical therapies are used in the treatment of RA: (1) NSAIDs, (2) glucocorticoids, and (3) DMARDs (both conventional and biologic).

1. **Nonsteroidal anti-inflammatory drugs (NSAIDs):** NSAIDs produce **symptomatic relief** because of its **analgesic and anti-inflammatory properties**. However, they do not alter the underlying disease process. Therefore, they are not used without the concomitant use of DMARDs. Their **chronic use should be minimized** because of its side effects such as gastritis/peptic ulcer disease and impairment of renal function.
2. **Glucocorticoids:** These are the most potent anti-inflammatory treatments available and cause dramatic and rapid improvement. Not only they produce symptomatic improvement, but also significantly decrease the radiographic progression of RA. However, the long-term therapy is associated with multisystem toxicities.
   - **Prednisolone** is the most commonly used glucocorticoid and is administered orally.
   - **Bridge therapy:** In 'bridge therapy', glucocorticoids are used first to shut off inflammation rapidly and then to taper them as the DMARD is taking effect.
   - **Pulse therapy:** Remission is induced with IM (intramuscular) depot methylprednisolone 80–120 mg if synovitis persists beyond 6 weeks. Intra-articular long-acting glucocorticoids (e.g. triamcinolone hexacetonide) are used to reduce synovitis.
3. **Disease modifying antirheumatic drugs (DMARDs).**

Q. Describe the basis for biologics and DMARDs in rheumatologic diseases.

Q. Describe the role and current status of various disease modifying antirheumatic drugs (DMARDs).

Patients with RA must be started on DMARD therapy as soon as possible. DMARDs have the ability to inhibit greatly the disease process to modify or change the disabling potential of RA. DMARDs are so named because in most of the cases they are able to slow or prevent structural (radiographic) progression of RA.

Box 8.2: Conventional DMARDs used in RA.

- Methotrexate (MTX)
- Hydroxychloroquine
- Sulfasalazine
- Leflunomide
- Azathioprine
- Gold (auranofin)
- Minocycline
- D-penicillamine

Conventional DMARDs used in RA (Box 8.2)

- Conventional DMARDs exhibit a delayed onset of action and take 2–6 months to exert their full effect.
- Start DMARD therapy early in the disease process. Early in the course of disease, most patients should be started on a combination of DMARDs and analgesics. Before using DMARDs, complete blood count, serum creatinine, aminotransferases, and screening for hepatitis C, hepatitis B, and latent tuberculosis infection. A chest radiograph should be obtained prior to initiating treatment with MTX.

Methotrexate: Currently, methotrexate is the DMARD of choice (considered as 'gold standard' drug) for RA and is the anchor drug for most combination therapies.

- **Mechanism of action** in RA: At the dosages used for RA, methotrexate stimulates extracellular release of adenosine from cells, which has anti-inflammatory and immunomodulatory properties. Enzymes inhibited by methotrexate in RA include **thymidylate synthetase (TS) and 5-aminoimidazole-4-carboxamide ribonucleotide (AICAR) transformylase**. **It should not be prescribed in pregnancy.**
- **Dose:** Usually given orally in the starting dose of 2.5–7.5 mg**/week** as a single dose. **If there is no positive response** within 4–8 weeks, and there is no toxicity, the dose should be **increased by 2.5–5 mg/week** each month to 15–25 mg/week before considering, the treatment a failure. Oral absorption of methotrexate is variable. If oral treatment is not effective, it is given by subcutaneous injections. It should be monitored with full blood counts and liver biochemistry.
- **Folic acid**, 1 to 4 mg/day (or 5 mg once a week, on the day following methotrexate dose), reduces most methotrexate associated toxicities (e.g. gastrointestinal intolerance, stomatitis, hepatotoxicity, hyperhomocysteinemia, alopecia) without apparent loss of efficacy.

If methotrexate alone does not sufficiently control RA, it is combined with other DMARDs.

Other DMARDs

- **Hydroxychloroquine** is used usually in combination with other DMARDs, particularly methotrexate. It is given orally at a dose of 200–400 mg daily. It is the least toxic DMARD but also the least effective as monotherapy. Regular monitoring (every 6 months to a year) by ophthalmoscopy to detect any signs of retinopathy, bull's eye maculopathy should be done.
- **Sulfasalazine:** It is effective when given in doses of 1–3 g daily. Monitoring of blood cell counts is recommended, particularly WBC counts, in the first 6 months. Combination of sulfasalazine + hydroxychloroquine + methotrexate is referred to as triple therapy.
- **Triple therapy:** MTX + HCQ + Sulfasalazine in patients who do not reach remission with dual therapy.
- **Leflunomide** is a pyrimidine antagonist, also inhibits enzyme **dihydroorotate dehydrogenase**, interfering with cell signal transduction. It has a very long half-life and is given daily in a dose of 10–20 mg. The most common toxicity is diarrhea, which may respond to dose reduction. Leflunomide is teratogenic and hepatotoxic. It is used as monotherapy or in combination with methotrexate and other DMARDs.
- **Others:** These include minocycline, gold salts, penicillamine and cyclosporine are used sparingly now.

Biologic DMARDs/Biologicals

Q. List the biologicals used in the treatment of rheumatoid arthritis (RA).

- They are usually given along with methotrexate or other conventional DMARDs.
- **Disadvantages: High cost** and **long-term toxicities,** notably **infections** (especially cellulitis, septic joints, tuberculosis, histoplasmosis, coccidioidomycosis, and *Listeria*) and **demyelinating syndromes**.

TNF-α Blockers

- **Etanercept,** a recombinant TNF receptor fusion protein. Administered subcutaneously in a dose of 25 mg twice weekly.
- **Infliximab** is a mouse/human chimeric monoclonal antibody against TNF-α. It is given intravenously (3–10 mg/kg) every 4–8 weeks.
- **Adalimumab** is a recombinant human IgG1 monoclonal antibody directed against TNF-α. It is administered subcutaneously in a dose of 40 mg every other week.
- Newer TNF inhibitors, certolizumab pegol and golimumab, are also effective.

IL-1 Receptor Blocker

Anakinra, a recombinant human interleukin-1 receptor antagonist. It is given subcutaneously in a dose of 100 mg daily.

IL-6 Inhibitor—Sarilumab and Tocilizumab

Tocilizumab is the first approved drug in a class of IL-6 inhibitors. Tocilizumab is effective in decreasing signs and symptoms and in slowing radiographic progression in RA patients who have failed other DMARD therapies. Recommended starting dose is 4 mg/kg followed by an increase to 8 mg/kg based on clinical response. *Side effects:* As with other biological DMARDs, there is an increased risk of infection. Because of a risk of GI perforation, patients with a history of diverticulitis should not receive tocilizumab. Tocilizumab has been associated with reduced platelet count, elevations in liver transaminases, increased lipid parameters.

Anti-CD20 Antibodies

Rituximab is a genetically engineered chimeric murine/human monoclonal antibody directed against the CD20 molecule found on the surface of B cells. It is given intravenously as two infusions 2 weeks apart for the treatment of patients with refractory RA.

T-cell Agent

Abatacept is a recombinant fusion protein of the extracellular domain of human CTLA4 and a fragment of the Fc domain of human IgG1. It is administered by intravenous infusion every 4 weeks in a dose of approximately 10 mg/kg.

JAK inhibitors

Tofacitinib, baricitinib, filgotinib, peficitinib, and upadacitinib, can also be used in combination with MTX. Should be used only after intolerance or inadequate response to one TNF-α inhibitor.

Immunosuppressants: These are used as third-line drugs for RA that recurs or does not respond to second-line agents. These include cyclophosphamide and azathioprine. However, in RA with acute vasculitis causing serious organ involvement, intravenous administration of cyclophosphamide may be lifesaving.

Surgery

Surgical therapy may improve pain and disability when there is a failure of medical therapy. It is useful in maintenance of joint function, and prevention and correction of deformities. Surgical procedures of the joint include (a) synovectomy of the inflamed joint before joint damage; (b) osteotomy to correct the deformity and relieve pain in the upper end of the tibia, and excision of the lower end of the ulna; (c) arthrodesis of the joint to relieve pain in the atlanto-axial joint, wrists, ankle and subtalar joints; (d) excision arthroplasty and (e) joint replacement.

Rheumatoid Arthritis in Pregnancy: HCQ, SSZ (sulfasalazine) and Azathioprine can be used. Lowest possible dose of glucocorticoids. NSAID's can be used upto 20 weeks, after 20 weeks it should be avoided except low dose aspirin. MTX and leflunomide are contraindicated.

Physiotherapy, Rehabilitation and Assistive Devices

Exercise and physical activity improve muscle strength. Judicious use of wrist splints can decrease pain.

Treatment algorithm for rheumatoid arthritis is presented in **Flowcharts 8.1 and 8.2**.

Felty's Syndrome

Q. Write short essay/note on Felty's syndrome and its components.

- Felty's syndrome is the triad of RA, neutropenia and splenomegaly.
- It is seen in patients with long-standing chronic, severe and seropositive RA.
- Autoantibodies to deiminated histones (predominantly histone H3) and neutrophil extracellular chromatin traps (NETs) are postulate as the cause.

Clinical Features

See **Box 8.3**.

FLOWCHART 8.1: Treatment algorithm for rheumatoid arthritis (<6 months of symptoms).

If single TNFi failure, use: non-TNFi +/- MTX or TNFi +/- MTX
If multiple TNFi failure, use: non-TNFi +/- MTX or tofacitinib +/- MTX
If single non-TNFi failure, use: another non-TNFi +/- MTX
If multiple non-TNFi failure, use: non-TNFi +/- MTX(if TNF naïve) or tofacitinib +/- MTX
If TNFi and non-TNFi failure, use: non-TNFi +/- MTX or tofacitinib +/- MTX

Laboratory Findings

- **Blood:** Neutropenia 3 (absolute neutrophil count below 2000/microL), anemia and thrombocytopenia.
- **Rheumatoid factor (RF):** High titers.
- **Circulating immune complexes (CIC):** Increased levels.

Treatment

- Do not require special specific therapy; instead **treat underlying severe RA**. Immunosuppressive agents particularly methotrexate and azathioprine are beneficial.
- G-CSF and GM-CSF can be tried.

Box 8.3: Clinical features of Felty's syndrome.

- Features of RA (rheumatoid arthritis)
- Splenomegaly
- Lymphadenopathy
- Skin pigmentation
- Fever
- Weight loss
  - Rarely recurrent infections and chronic leg ulcers
  - Vasculitis
  - Subcutaneous nodules
  - Portal hypertension
  - Higher risk of Hodgkin's lymphoma

Prognosis

Poor with an increased mortality due to increased incidence of severe infection.

- **Splenectomy is indicated in:** Severe and persistent neutropenia (<500 cells/mm^3), recurrent or serious bacterial infections, chronic, nonhealing leg ulcers, hypersplenism producing severe anemia or thrombocytopenic hemorrhage.

Markers of poor prognosis in RA: Long disease duration, RF and anti-CCP positivity, and poor functional status at presentation are the best predictors of subsequent disability and joint damage. Other factors include:

- Generalized polyarthritis involving both small and large joints (>13 total joints)
- Extra-articular disease, especially nodules and vasculitis
- Persistently elevated ESR or CRP
- ANA positivity (if also RF-positive)
- Radiographic erosions within 2 years of disease onset
- HLA-DR4

Nonsteroidal Anti-inflammatory Drugs (NSAIDs)

Nonsteroidal anti-inflammatory drugs are the most widely used drugs, but they have an increased risk of cardiovascular disease. Oral NSAIDs are used for the management of pain due to inflammation.

Mechanism of NSAID action: Arachidonic acid (AA) is derived from membrane phospholipid and its **metabolism occurs along two major enzymatic pathways namely; cyclooxygenase pathway (**produces prostaglandins by the cyclooxygenase) (COX) **and lipoxygenase pathway** (produces leukotrienes by 5-lipoxygenase).

Q. Write briefly on COX enzymes and COX-2 inhibitors.

Traditional NSAIDs versus COX-2 Inhibitors

- **Traditional NSAIDs** (e.g. ibuprofen, diclofenac, and naproxen) exert their anti-inflammatory effect by inhibiting synthesis of prostaglandin from arachidonic acid by blocking both COX enzymes. They do not have a disease-modifying effect in either osteoarthritis or inflammatory rheumatic diseases. Inhibition of COX-1 is required for anti-inflammatory and analgesic effects, but can damage the mucosa of stomach and duodenum and is associated with an increased risk of upper gastrointestinal ulceration, bleeding and perforation. Simultaneous administration of omeprazole (20 mg daily) or misoprostol (200 μg twice or 3 times daily) reduces the risk of NSAID-induced ulceration and bleeding. Other side-effects include fluid retention, renal impairment due to inhibition of renal prostaglandin production, and rashes.
- **COX-2 (cyclooxygenase-2) selective NSAIDs** (e.g. celecoxib, etoricoxib, etodolac, rofecoxib and valdecoxib) selectively inhibit COX-2. They have **analgesic** and **anti-inflammatory properties similar to traditional NSAIDs**. However, they are much less **likely to cause gastrointestinal toxicity** and have **minimal antiplatelet effects**. Similar to traditional NSAIDs, they can produce significant changes in renal function, and hence, should be cautiously used in patients with diabetes, dehydration and congestive heart failure. They **play an important role in the management of inflammation and pain caused by arthritis**. It has been observed that there is a higher risk of myocardial infarction and stroke (thromboembolic complications) in patients using COX-2 inhibitors compared to traditional NSAIDs. Hence, two COX-2 inhibitors namely rofecoxib and valdecoxib have been withdrawn. NSAIDs like diclofenac, nabumetone, meloxicam, and etodolac, are also relatively selective for COX-2 at lower doses.

Differences between Rheumatic Arthritis and Rheumatoid Arthritis (Table 8.11)

Q. Differentiate between rheumatic arthritis from rheumatoid arthritis.

SYSTEMIC LUPUS ERYTHEMATOSUS

Q. Describe the clinical manifestations, diagnosis and management of systemic lupus erythematosus (SLE).

- Systemic lupus erythematosus (SLE) is a chronic, **multisystemic autoimmune** disease that results from **immune system-mediated tissue damage** and is characterized by the presence of **broad spectrum of autoantibodies**.
- **Arthralgia and rashes** are the **most common clinical features,** whereas **cerebral and renal diseases** constitute **most serious problems**.
- **Age:** It usually occurs in young women between **20 to 30 years**, but may manifest at any age.
- **Sex:** It predominantly affects **women**, with female-to-male ratio of 9:1.

TABLE 8.11: Differences between rheumatic arthritis and rheumatoid arthritis.

	Rheumatic arthritis	*Rheumatoid arthritis*
Onset	Acute	Subacute/chronic
Joints involved	Major joints (e.g. knee), rarely involves small joints of hands/wrists/feet	Small joints, e.g. palm-finger (MCP) joints, joints of the wrist/feet
Joints spared	Spares hip joints	Spares distal interphalangeal (DIP) joint
Spine	Not involved	C1, C2 involved
Presentation	Migratory	Non-migratory, static
Morning stiffness	+/–	+++
Pattern of involvement	Asymmetrical	Symmetrical
Cause	Poststreptococcal	Immune
Deformities	Rare (Jaccoud)	Common
Nodules	Rare, located only subcutaneously, painless	Common, painful, located periarticular, pleura, internal organs
Criteria used for diagnosis	Jones	ACR/EULAR
Antibodies	ASO	RF/ACPA
Treatment	Penicillin/aspirin +/– steroids	DMARDs/biologics
Other systems involved	Cardiac, basal ganglia	All systems involved

(ASO: Antistreptolysin O; ACR: American College of Rheumatology; EULAR: European League against Rheumatism; RF: Rheumatoid factor; ACPA: Anticyclic citrullinated protein antibodies; DMARD: Disease modifying antirheumatic drugs)

Pathophysiology

Pathophysiology is complex, however antibodies, immune complexes and complement activation plays an important role.

- **Autoantibody production**: In SLE, B cells of the immune system produce autoantibodies that target the body's own cells and tissues. The autoantibodies commonly found in SLE are antinuclear antibodies (ANA). They recognize and bind to various nuclear components, including DNA, histones, ribonucleoproteins, and other nuclear antigens.
- **Immune complex formation**: The binding of autoantibodies to self-antigens leads to the formation of immune complexes. These immune complexes consist of autoantibodies bound to their target antigens. They can circulate in the blood and deposit in various tissues, including the kidneys, skin, joints, and blood vessels.
- **Complement activation**: The immune complexes formed in SLE can activate the complement system, which is a group of proteins that play a critical role in the immune response. Activation of the complement cascade can occur through the classical pathway, triggered by the binding of complement proteins to immune complexes. This results in the release of inflammatory mediators, such as C3a and C5a, and the formation of the membrane attack complex (MAC), which can directly damage cells.
- **Inflammation and tissue damage**: The deposition of immune complexes in tissues and the activation of the complement system lead to chronic inflammation. Inflammatory mediators, including cytokines and chemokines, attract immune cells to the affected tissues. Neutrophils, macrophages, and other immune cells contribute to tissue damage through the release of enzymes, reactive oxygen species, and pro-inflammatory molecules. This chronic inflammation can affect multiple organs and systems, resulting in a wide range of clinical manifestations.
- **Abnormal T-Cell function**: T cells, another crucial component of the immune system, play a role in regulating immune responses. In SLE, there is an imbalance in T-cell subsets, particularly an increase in autoreactive CD4+ T cells. These autoreactive T cells can recognize self-antigens presented by antigen-presenting cells (APCs) and provide help to B cells, leading to the production of autoantibodies. They can also directly contribute to tissue inflammation by releasing pro-inflammatory cytokines, such as interleukin-17 (IL-17).
- **Defective clearance of apoptotic cells**: Apoptosis, or programmed cell death, is a normal process that occurs in the body to remove aged or damaged cells. In SLE, there is a defect in the clearance of apoptotic cells. Normally, apoptotic cells are rapidly cleared by phagocytic cells, such as macrophages. However, in SLE, apoptotic cells may not be efficiently cleared, leading to their accumulation. The release of self-antigens from these dying cells can trigger an immune response and contribute to the production of autoantibodies.
- **Type I interferon (IFN) production**: SLE is characterized by increased production of type I interferons, particularly interferon-alpha (IFN-α). Type I interferons are cytokines that play a crucial role in the immune response to viral infections. In SLE, there is activation of plasmacytoid dendritic cells (pDCs), which are specialized immune cells that produce large

amounts of IFN-α in response to immune complex stimulation. The increased production of type I interferons can further stimulate the immune system, enhance the presentation of self-antigens, and promote inflammation.

Clinical Features (Table 8.12)

Q. **Write short essay/note on clinical features of systemic lupus erythematosus (SLE).**

TABLE 8.12: Common clinical manifestations of SLE.

		Clinical manifestations	
System involved	***%***	***Common***	***Uncommon***
Systemic	95	Fatigue, malaise, fever, anorexia, nausea, weight loss	Generalized lymphadenopathy
Musculoskeletal	95	Arthralgias/myalgias, non-erosive polyarthritis, myopathy	Myositis, erosive (Jaccoud's) arthritis
Mucocutaneous	80	Photosensitivity, malar rash ('butterfly' rash), oral ulcers, alopecia, discoid rash, Raynaud phenomenon, livedo reticularis, panniculitis, splinter hemorrhages	Angioedema, bullous lupus, cutaneous vasculitis thromboembolic manifestations
Hematological	85	Anemia, leukopenia (<4000/µL), lymphopenia (<1500/µL), thrombocytopenia (100,000/µL), lymphadenopathy, splenomegaly, hemolytic anemia	
Neuropsychiatric	60	Delirium, psychosis, seizures, mono/polyneuropathy, mood disorder, headache, stroke (thromboembolic)	Cranial neuropathy, chorea
Cardiopulmonary	60	Pericarditis/pericardial effusions, coronary artery disease, pleurisy/pleural effusions, lupus pneumonitis, pulmonary hypertension, intestitial lung disease	Myocarditis, Libman-Sacks endocarditis, pulmonary hemorrhage Congenital heart block (neonatal lupus) shrinking lung syndrome
Renal	30–50	Proteinuria 500 mg/24 h, cellular casts, nephrotic syndrome, renal failure	
Gastrointestinal	40	Non-specific symptoms (nausea, mild pain, diarrhea), bleeding or perforation, abnormal live enzymes	Mesenteric vasculitis (with or without ischemia), colitis, splenomegaly
Thrombosis	15	Venous and arterial	
Ocular	15	Sicca syndrome, conjunctivitis, episcleritis, retinal vasculitis	Optic neuritis, uveitis, retinitis
Vasculitis	11–36	Cutaneous, visceral, retinal, pulmonary vasculitis	
Others		Antiphospholipid antibody syndrome, osteoporosis	Inmmunodeficiency

Musculoskeletal Manifestations

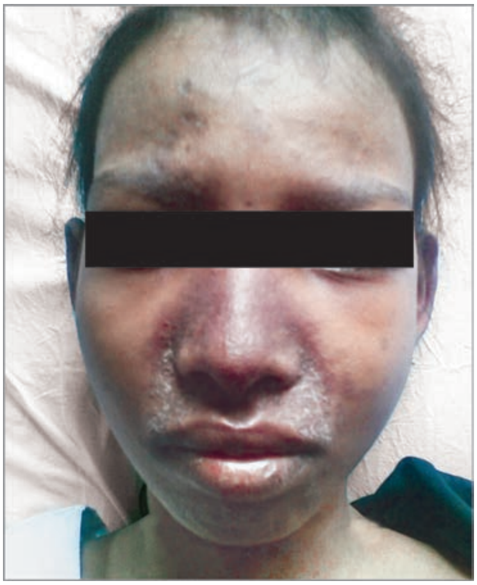
- Arthralgia and nonerosive arthritis are most common (>85%). Commonly involves proximal interphalangeal and metacarpophalangeal joints of the hand, along with the knees and wrists.
- In about 10% of patients, **deformities result from damage to periarticular** tissue, a condition termed **Jaccoud's arthropathy**.

Cutaneous Manifestations

- **Classic malar rash** consists of erythematous (flat or raised) facial rash with a **butterfly distribution** across the malar and nasal prominences and sparing of the nasolabial folds **(Fig. 8.3)** and is seen in 30–60% of patients. Butterfly rash is **often triggered by sun exposure**.
- **Discoid lupus** is a benign variant of lupus in which **only the skin is involved**. Discoid rash consists of erythematous, slightly raised patches with adherent keratotic scaling and follicular plugging. Discoid rash without any systemic features occurs in discoid lupus erythematosus (DLE). Only 5% of patients with DLE have SLE; however, as many as 20% SLE patients have DLE. This rash is primarily seen on the face and scalp.
- Generalized **photosensitivity** (skin rash on exposure to sunlight) and alopecia.

Mucous Membrane Manifestations

Recurrent crops of small, painful ulcerations on the oral or nasal mucosa. Dryness secondary to Sjögren's syndrome.



[redacted]

FIG. 8.3: Systemic lupus erythematosus with malar rash and alopecia.

Hematologic Manifestations

Antibodies that target each of the cellular blood elements are responsible for hematological changes.

- RBC: Normocytic normochromic **anemia**, reflecting chronic illness. **Hemolytic anemia:** Coombs' test positive or microangiopathic hemolysis.
- WBC: **Leukopenia**, particularly lymphopenia.
- Platelets: **Idiopathic/immune thrombocytopenic purpura** induced by antiplatelet antibodies.
- Antibodies to clotting factors can contribute to impaired clot formation and hemorrhage.

Renal Manifestations

Q. **Enumerate the renal manifestations of SLE.**

- Kidney may be **involved in 30–50%** of SLE patients and is one of the most important organs involved.
- **Often asymptomatic** in most lupus patients, particularly initially. Hence, **urinalysis should be done** in any person suspected of having SLE followed by regular urinalysis and blood pressure monitoring.
- Characterized by proteinuria (>500 mg/24 hours) and/or cellular (red cell) casts.
- Histological classification of lupus nephritis **(Table 8.13)**.

TABLE 8.13: ISN/RPS classification of lupus nephritis.

Class	*Histological type*
I	Minimal mesangial lupus nephritis (light microscopy: normal glomeruli)
II	Mesangial proliferative LN (few isolated subepithelial/endothelial deposits visible by IF or electron microscopy)
III	Focal lupus nephritis (<50% glomeruli, subendothelial deposits)
➤ IIIA	Active lesions
➤ IIIA/C	Active and chronic lesions
➤ IIIC	Chronic lesions
IV	Diffuse lupus nephritis >50% glomerul involved, segmental and global lesions
➤ IV–S (A)	Active lesions—diffuse segmental proliferative lupus nephritis
➤ IV–G (A)	Active lesions—diffuse global proliferative lupus nephritis
➤ IV–S (A/C)	Active and chronic lesions—diffuse segmental proliferative and sclerosing lupus nephritis
➤ IV–G (A/C)	Active and chronic lesions—diffuse global proliferative and sclerosing lupus nephritis
➤ IV–S (C)	Chronic in active lesions with scars—diffuse segmental sclerosing lupus nephritis
➤ IV–G (C)	Chronic in active lesions with scars—diffuse segmental global lupus nephritis
V	Membranous lupus nephritis
VI	Advanced sclerosing lupus nephritis

Neuropsychiatric Features

- Nervous system involvement in SLE produces both neurologic and psychiatric manifestations.
- Clinical features include cognitive dysfunction (due to SLE cerebritis), headache and seizures, psychiatric features including depression and psychosis. Peripheral nervous system involvement can cause neuropathy. Cranial nerve and ocular involvement due to vasculopathy.

Cardiac Manifestations

- **Pericarditis most frequent**; serious manifestations are myocarditis and **Libman-Sack (**noninfective endocarditis involving the mitral valve) **endocarditis.**
- **Increased risk for myocardial infarction**, usually due to accelerated atherosclerosis and vasculitis.

Pulmonary Manifestations

- **Pleural lesions:** Pleurisy with or without pleural effusion—most common pulmonary manifestation. Pleural effusion is exudative with low C3 and ANA test positive in the pleural fluid.
- **Lung lesions:** Pneumonitis (exclude infection before ascribing a lung lesion to SLE), shrinking lung syndrome, interstitial inflammation leading to fibrosis and intra-alveolar hemorrhage.

Gastrointestinal Features

Non-specific diffuse abdominal pain (caused by autoimmune peritonitis and/or intestinal vasculitis), nausea sometimes with vomiting and diarrhea. Increases in serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT). Mesenteric vasculitis can cause infarction or perforation of small intestine.

Ocular Manifestations

- Sicca syndrome (Sjogren's syndrome) and nonspecific conjunctivitis are common.
- Serious manifestations are retinal vasculitis (can cause infarcts and cytoid bodies) and optic neuritis. Complications of glucocorticosteroid therapy include cataracts (common) and glaucoma.

Other Manifestations

Kikuchi-Fujimoto disease (splenomegaly, lymphadenopathy), antiphospholipid syndrome, osteoporosis, and complement deficiencies are associated with SLE. Increased risk of hematologic malignancies (particularly non-Hodgkin's lymphoma) and possibly lung and hepatobiliary cancers.

Poor progmnostic factors in SLE include diffuse proliferative glomerulonephritis, male sex, older age at presentation, black race, hypertension and antiphospholipid antibody syndrome.

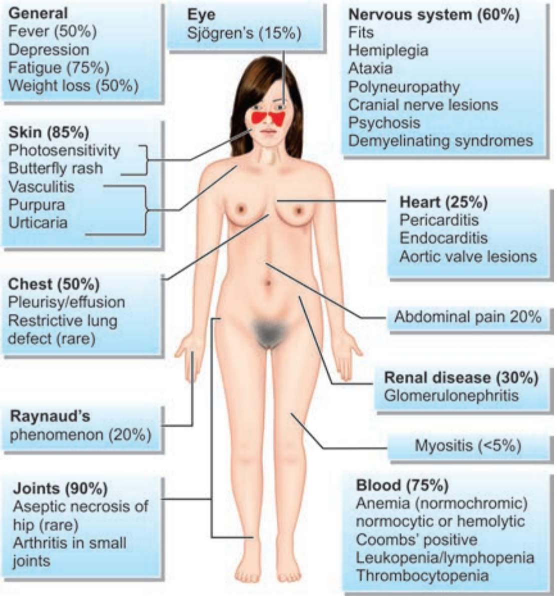
Clinical features are summarized diagrammatically in **Figure 8.4**. Causes of death in SLE are listed in **Box 8.4**.

Box 8.4: Causes of death in SLE.

- **Infections and renal failure:** Cause of death in the first decade of disease
- **Thromboembolic events:** Cause of death in the second and later decades
- **Cardiovascular:** Due to premature atherosclerosis

Laboratory Findings

Purpose: (1) To establish or rule out the diagnosis, (2) follow the course of disease, and (3) to identify adverse effects of therapies.



General
Fever (50%)
Depression
Fatigue (75%)
Weight loss (50%)
Eye
Sjögren's (15%)
Nervous system (60%)
Fits
Hemiplegia
Ataxia
Polyneuropathy
Cranial nerve lesions
Psychosis
Demyelinating syndromes
Skin (85%)
Photosensitivity
Butterfly rash
Vasculitis
Purpura
Urticaria
Heart (25%)
Pericarditis
Endocarditis
Aortic valve lesions
Chest (50%)
Pleurisy/effusion
Restrictive lung defect (rare)
Abdominal pain 20%
Renal disease (30%)
Glomerulonephritis
Raynaud's phenomenon (20%)
Myositis (<5%)
Joints (90%)
Aseptic necrosis of hip (rare)
Arthritis in small joints
Blood (75%)
Anemia (normochromic) normocytic or hemolytic
Coombs' positive
Leukopenia/lymphopenia
Thrombocytopenia

FIG. 8.4: Clinical features of systemic lupus erythematosus (SLE).

Autoantibodies in SLE

Q. Describe the diagnostic work up and the role of autoantibodies in systemic lupus erythematosus (SLE).

- SLE is characterized by the production of **several diverse autoantibodies**. Some antibodies are against different nuclear and cytoplasmic components of the cell that are not organ specific. Other antibodies are directed against specific cell surface antigens of blood cells.
- **Importance of autoantibodies:** (1) **Diagnosis and management** of patients with SLE, and (2) responsible for **pathogenesis of tissue damage.**

Types of Antibodies (Table 8.14)

- **Antinuclear antibody (ANA):** Best screening test and >90% of the patients show a positive test. However, a positive test is not specific for SLE. It can be positive in some normal individual (especially elderly), other autoimmune diseases, acute viral infections, chronic inflammatory processes and with certain drugs.

TABLE 8.14: Autoantibodies in patients with systemic lupus erythematosus (SLE).

- Antinuclear antibodies (ANA)
- Anti-dsDNA (ds = double stranded)
- Anti-Sm (Anti-Smith)
- Anti-RNP
- Anti-Ro (SSA)
- Anti-La (SSB)
- Antihistone
- Antiphospholipid
- Antierythrocyte
- Antiplatelet
- Antineuronal
- Antiribosomal

- **Anti-double-stranded DNA** (anti-dsDNA) antibodies are common in SLE. **Anti-Sm antibodies are highly specific** for SLE. Rising levels of anti-dsDNA and low levels of complement (C3 and C4) usually reflect disease activity.
- **Rheumatoid factor** is positive in 30%.

Other Tests

- **Complete blood count:** Essential and aids in diagnosis and management. **Anemia** (normocytic normochromic and Coombs' positive), **leucopenia, lymphopenia** and **thrombocytopenia** may be present.
- **Activated partial thromboplastin time (aPTT): Prolonged** in the presence of pathogenic **antiphospholipid antibodies**. These antibodies give a false-positive result in the serologic test for syphilis.
- **Erythrocyte sedimentation rate (ESR):** Nonspecific indicator of systemic inflammation. It is often monitored in many patients to know the disease activity.
- **C-reactive protein (CRP):** It is an acute phase reactant which is relatively uninformative and normal in SLE. It does not usually rise with disease activity unless there is infection, arthritis or serositis.
- **Urinalysis:** When there is active nephritis, urinalysis shows proteinuria, hematuria and cellular (red and white blood cell casts in the urinary sediment suggest proliferative glomerulonephritis) or granular casts. Blood urea nitrogen and serum creatinine are elevated in acute kidney injury. If there is proteinuria, urine albumin/creatinine ratio should be measured. Renal biopsy confirms renal involvement.

- **Complement levels:** Low levels of C3 indicate active disease especially nephritis.
- **LE cell:** Phagocytic leukocyte (neutrophil or macrophage) that has engulfed the denatured nucleus of an injured cell is positive. Rarely done nowadays.

Imaging

- **Chest X-ray:** To exclude other pathology, for pulmonary and cardiac pathology.
- **High resolution CT:** To demonstrate fibrotic lung.
- **Magnetic resonance imaging (MRI)** of brain or spinal cord in cases with central nervous system disease involvement.
- Echocardiography to diagnose pericardial and endocardial involvement.
- **Renal biopsy:**
  Indications are: Increasing serum creatinine without a compelling alternative cause (e.g., hypovolemia and medication)
    - Confirmed proteinuria of ≥1 g/24 hours
    - Proteinuria ≥0.5 g/day plus hematuria or cellular casts

Diagnostic Criteria for Systemic Lupus Erythematosus

Q. List the diagnostic criteria/revised American Rheumatism Association criteria for systemic lupus erythematosus (SLE).

The clinical presentation of SLE is so variable that the American College of Rheumatology has established a complex set of criteria **(Table 8.15)**.

TABLE 8.15: 2019 European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) classification criteria for systemic lupus erythematosus.

Entry criterion ***Antinuclear antibodies (ANA) at a titer of ≥:80 on HEp-2 cells or an equivalent positive test (ever)***			
If absent, do not classify as SLE; If present, apply additive criteria			
Additive criteria			
Do not count a criterion if there is a more likely explanation than SLE. Occurrence of a criterion on at least one occasion is sufficient. SLE classification requires at least one clinical criterion and ≥10 points.		Criteria need not occur simultaneously. Within each domain, only the highest weighted criterion is counted toward the total score§	
Clinical domains and criteria	**Weight**	**Immunology domains and criteria**	**Weight**
Constitutional		**Antiphospholipid antibodies**	
Fever	2	Anti-cardiolipin antibodies **OR** Anti-β2GP1 antibodies **OR** Lupus anticoagulant	2
Hematologic			
Leukopenia Thrombocytopenia Autoimmune hemolysis	3 4 4	**Complement proteins** Low C3 **OR** low C4 Low C3 **AND** low C4	3 4
Neuropsychiatric		**SLE-specific antibodies**	
Delirium Psychosis Seizure	2 3 5	Anti-ds-DNA antibody* **OR** Anti-Smith antibody	6
Mucocutaneous			
Non-scarring alopecia Oral ulcers Subacute cutaneous OR discoid lupus Acute cutaneous lupus	2 2 4 6		
Serosal		**NOTE:** § = additional criteria within the same domain will not be counted; * = in an assay with 90% specificity against relevant disease controls. Anti = b2GPI = anti-b2-glycoprotein I; antl-ds-DNA = anti-double stranded DNA.	
Pleural or pericardial effusion Acute pericarditis	5 6		
Musculoskeletal Joint involvement			
Renal			
Proteinuria >0.5g/24h Renal biopsy Class II or V lupus nephritis Renal biopsy Class III or IV lupus nephritis	4 8 10		
Total score **Classify as Systemic Lupus Erythematosus with a score of 10 or more if entry criterion fulfilled**			

Systemic Lupus International Collaborating Clinics (SLICC) Classification 2012 criteria* **(Table 8.16)**.

TABLE 8.16: Systemic Lupus International Collaborating Clinics (SLICC) Classification 2012 criteria.

Lupus nephritis proved by biopsy and ANA or anti-DNA or at least 4 criteria (1 needs to be immunological)

Clinical	*Immunological*
Acute cutaneous LE	ANA
Chronic cutaneous LE	Anti-dsDNA
Oral ulcer	Anti-Sm
Alopecia	aPL antibodies
Synovitis	Low complement
Serositis	Direct Coombs' test positive
Renal	
Neurologic	
Hemolytic anemia	
Leukopenia/lymphopenia	
Thrombocytopenia	

Differences between rheumatoid arthritis and systemic lupus erythematosus are presented in **Table 8.17**.

TABLE 8.17: Differences between rheumatoid arthritis and systemic lupus erythematosus.

Features	*Rheumatoid arthritis*	*Systemic lupus erythematosus*
Smoking	Predisposing factor	No relation
Female:Male	3:1	9:1
Type of arthritis	Erosive	Non-erosive
Deformities	Common	Rare, Jaccoud's arthropathy (10%)
Systemic involvement	Relatively less	Marked
Nodules	Rheumatoid nodules	Absent
Malar (skin) rash	Nil	Striking feature: malar rash, discoid rash
Photosensitivity	Absent	Photosensitivity present
Oral ulcer and alopecia	Absent	Present
Spine involvement	Involves cervical spine	Rare
Pyoderma gangrenosum	May develop	Rare
Renal involvement	Uncommon	Common and severe
Platelet abnormality	Thrombocythemia	Thrombocytopenia
Serology	RA factor and ACPA	ANA and anti-dsDNA
Criteria for diagnosis	ACR/EULAR	SLICC/ACR
Response to DMARDs	Present	Less response

(ACPA: Anticyclic citrullinated peptide antibodies; ANA: Antinuclear antibodies; ds: double stranded; ACR: American College of Rheumatology; EULAR: European League Against Rheumatism; SLICC: Systemic Lupus International Collaborating Clinics Classification)

Management (Flowchart 8.3)

Q. Describe the management principles of systemic lupus erythematosus.

General

- To avoid known triggers of disease exacerbation, such as ultraviolet light, smoking cessation.
- Need for adequate rest.

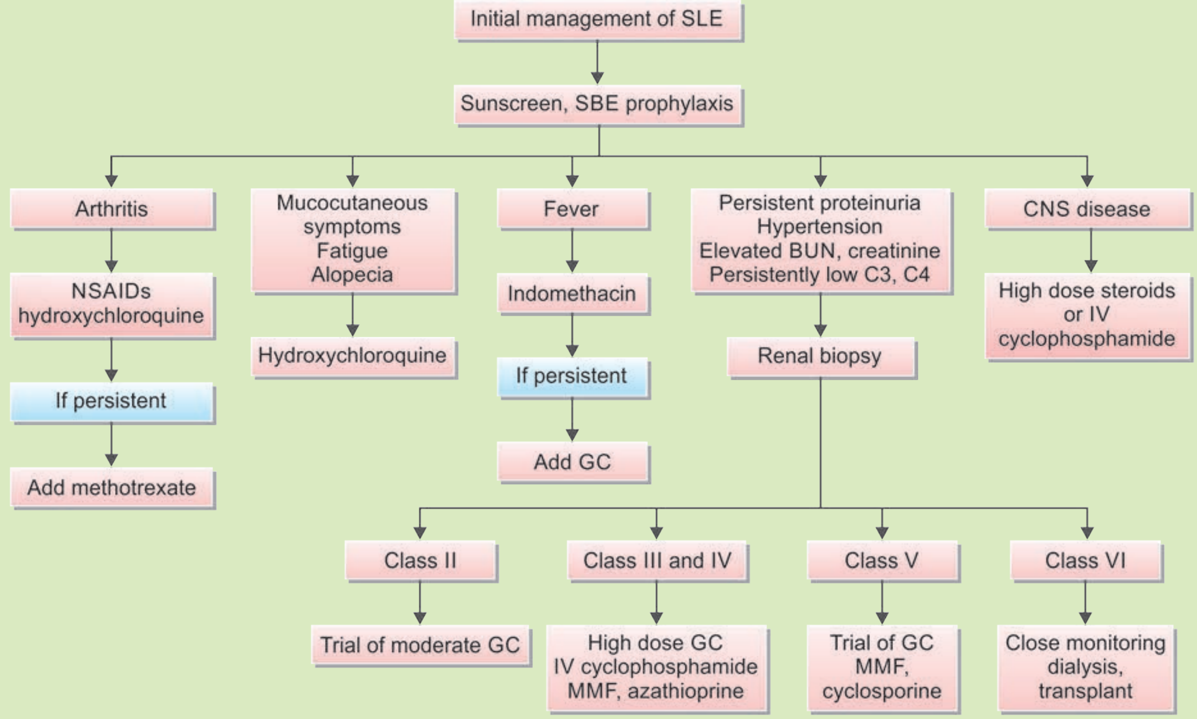
Conservative therapies for management of non-life-threatening disease

In patients with fatigue, pain, and autoantibodies of SLE, but without major organ involvement are managed by analgesics (**NSAIDs**), antimalarials (**hydroxychloroquine**, chloroquine, and quinacrine) and **low-dose corticosteroids**. Skin lesions and arthritis also respond to hydroxychloroquine. Photosensitive skin lesions need application of sunscreen lotions.

Life-threatening SLE: Proliferative forms of lupus nephritis

- Life-threatening SLE or patients with severe symptoms should receive **corticosteroids**.
- Acutely ill-patients and patients with active proliferative glomerulonephritis may be treated with prednisone at 60 mg daily or 1 g of intravenous methylprednisolone administered daily for 3 days.

FLOWCHART 8.3: Treatment algorithm for systemic lupus erythematosus.



Initial management of SLE
Sunscreen, SBE prophylaxis
Arthritis
NSAIDs hydroxychloroquine
If persistent
Add methotrexate
Mucocutaneous symptoms Fatigue Alopecia
Hydroxychloroquine
Fever
Indomethacin
If persistent
Add GC
Persistent proteinuria Hypertension Elevated BUN, creatinine Persistently low C3, C4
Renal biopsy
CNS disease
High dose steroids or IV cyclophosphamide
Class II
Trial of moderate GC
Class III and IV
High dose GC IV cyclophosphamide MMF, azathioprine
Class V
Trial of GC MMF, cyclosporine
Class VI
Close monitoring dialysis, transplant

Mild SLE		Moderate to severe SLE	
Constitutional symptoms	HCQ with or without low dose systemic GC or methotrexate; then azathioprine, methotrexate or mycophenolate; then Rituximab or Belimumab	**Alveolitis**	Systemic GC + Mycophenolate or IV Cyclophosphamide; then add rituximab or IV immunoglobulin, maintain with azathioprine or mycophenolate
		Antiphospholipid syndrome	Anticoagulation, with or without HCQ, then add direct thrombin inhibitor
Discoid lupus	Sunscreen, topical corticosteroids, tacrolimus, topical acitretin, with or without HCQ, with or without systemic glucocorticoids, then add azathioprine or switch with mycophenolate or methotrexate	**Mononeuritis**	Systemic GC with or without IV cyclophosphamide, then add rituximab, IV immunoglobulin or plasmapheresis
		Thrombocytopenia	Systemic GC with or without HCQ, then add azathioprine or mycophenolate, then add rituximab or IV cyclophosphamide or IV immunoglobulin
Polyarthritis	HCQ with or without low dose systemic glucocorticoids, then add methotrexate or rituximab, NSAIDs-adjunctive therapy	**Lupus nephritis**	Systemic GC + mycophenolate, then IV cyclophosphamide, then add rituximab or switch to azathioprine; angiotensin-converting enzyme inhibitor and HCQ as adjunctive therapy
Uncomplicated digital or cutaneous vasculitis	Systemic glucocorticoids, with or without HCQ, with or without methotrexate then add azathioprine or mycophenolate, then switch to IV cyclophosphamide	**Myocarditis**	Systemic GC + IV cyclophosphamide, with or without HCQ, then rituximab, belimumab or IV immunoglobulin
		Pericarditis	NSAIDs, systemic GCs + HCQ, then add mycophenolate, azathioprine or methotrexate; then add belimumab or rituximab
		Pulmonary artery hypertension	Systemic GC + IV cyclophosphamide, or mycophenolate + endothelin receptor antagonist, then add rituximab and PDE-5 inhibitor, then add prostaglandin analogue and maintain with it.

- **Immunosuppressive agents:** These include azathioprine, methotrexate, cyclophosphamide, mycophenolate mofetil and are also useful in controlling severe disease. They are particularly useful in patients with renal involvement. A combination of intravenous cyclophosphamide and steroids is the most effective regimen. Following intravenous cyclophosphamide, oral mycophenolate mofetil is an alternative to maintain remission.
- Drugs targeting B-cell pathways, such as belimumab and rituximab are used in refractory cases.
- **New update: Anifrolumab, a human monoclonal antibody against IFN receptor subunit 1 (IFN was approved by US FDA for treatment of moderate to severe disease).**

Drug-induced Lupus

Q. Write short essay/note on drug-induced lupus.

It is a syndrome consisting of positive ANA associated with symptoms such as fever, malaise, arthritis or intense arthralgias/myalgias, serositis and/or rash.

Etiology: The syndrome develops during therapy with certain medications and includes:

- **Drugs:** Antiarrhythmics (e.g. procainamide, diltiazem, disopyramide, and propafenone), antihypertensive (e.g. hydralazine), methyl dopa, angiotensin-converting enzyme inhibitors, beta blockers, antithyroid propylthiouracil, antipsychotics (e.g. chlorpromazine and lithium), anticonvulsants (e.g. carbamazepine and phenytoin), antibiotics (e.g. isoniazid, minocycline, and macrodantin), antirheumatic (e.g. sulfasalazine), diuretic (e.g. hydrochlorothiazide) and antihyperlipidemics (e.g. lovastatin and simvastatin).
- **Biologic agents:** Interferons and TNF inhibitors.

Symptoms: Usually resolve after discontinuation of the offending drug.

Box 8.5 lists the features that differentiate drug-induced lupus from SLE.

Box 8.5: Features that differentiate drug-induced lupus from SLE.

Drug-induced lupus
- Less female predilection than SLE
- Kidneys or brain involvement rare, less cutaneous involvement
- Antinuclear antibodies positive; antihistone antibodies
- Positive (95%); autoantibodies to dsDNA absent
- C3 levels normal

Seronegative Arthritis

Q. Differentiate seropositive arthritis from seronegative arthritis.

- Arthritis can be divided into seropositive and seronegative.
- Seropositive arthritis refers to the presence of rheumatoid factor and anti-CCP in the blood.
- Seronegative arthritis generally called 'seronegative spondyloarthropathy' and include ankylosing spondylitis, psoriatic arthritis and reactive arthritis.

SPONDYLOARTHROPATHIES (SPONDYLOARTHRITIDES)

Q. Write short essay/note on spondyloarthropathies.

Q. Write short essay/note on seronegative spondyloarthropathies (SSA).

Definition: The spondyloarthropathies (SpAs) are a group of related inflammatory joint diseases **(Box 8.6)** that share clinical features and genetic susceptibility.

Box 8.6: Diseases included under spondyloarthropathies (SpAs).

- Ankylosing spondylitis (AnS)
- Reactive arthritis (ReA) (including Reiter's syndrome)
- Psoriatic arthritis (PsA)
- Arthropathy associated with inflammatory bowel disease
- Undifferentiated spondyloarthritis

Common Features of SpAs

- **Common clinical features:**
  - Strong predilection for the **spine**, in particular the **sacroiliac joints. Inflammatory back pain** due to sacroiliitis and spondylitis.
  - **Tendency for new bone formation** at sites of chronic inflammation, with **joint ankylosis** as a consequence.
  - If **peripheral arthritis** occurs, it is usually in the **lower extremity and asymmetrical**.
  - **Predilection for sites of tendon insertion into bone (enthesis). Enthesitis** is inflammation at sites where tendons, ligaments or joint capsules attach to bone and is one of the **most specific clinical manifestations** of the SpAs.
  - RF negative; hence, known as **'seronegative'**.
- **Common genetic predisposing factor:** All subsets have an association with **HLA-B27 allele.**

Ankylosing Spondylitis

Q. Discuss the clinical features, diagnosis and management ankylosing spondylitis, rheumatoid spondylitis or Bekhterev-Strümpell-Marie disease.

Ankylosing spondylitis (AnS) is a chronic inflammatory disorder of unknown causes that primarily affects the axial skeleton (predominantly sacroiliac joints and spine). The peripheral joints and extra-articular structures are also frequently involved.

Age and gender: Usually begins in the second or third decade; male to female ratio is between 2:1 and 3:1.

Clinical Features

Targets in ankylosing spondylitis (Fig. 8.5): Mainly involves spine, sacroiliac joints and large peripheral joints (hip, shoulder) in an asymmetrical pattern.

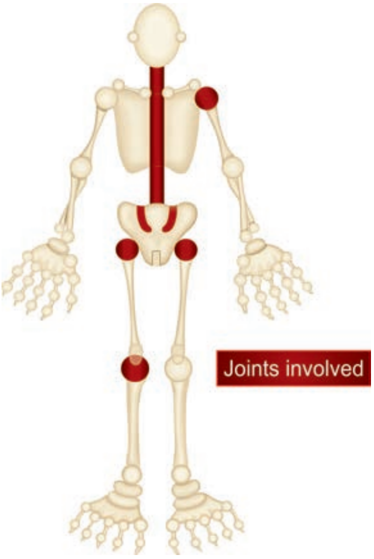


FIG. 8.5: Pattern of joint involvement in ankylosing spondylitis.

Involvement of lumbar spine

- Classical presentation is the **insidious onset of inflammatory low back pain**. The pain is dull and located in the lower lumbar regions or gluteal region and shows nocturnal exacerbation.
- Back pain persists for >3 months. It is accompanied by **early-morning stiffness** that typically **improves with activity**/exercise and **exacerbated by inactivity**.
- "Inflammatory back pain" typically exhibits at least four of the following five features:
    i. Age of onset <40 years
    ii. Insidious onset
    iii. Improvement with exercise
    iv. No improvement with rest
    v. Pain at night
- **Physical examination:** Physical examination of the spine shows loss of spinal mobility in all directions and pain on sacroiliac stressing.
- **Modified Schober test:** Used to measure lumbar spine flexion. The patient stands upright with heels together. Two marks are made on the spine; one at the lumbosacral junction (identified by a horizontal line between the posterosuperior iliac spines) and another 10 cm above. The patient then bends forward maximally with knees fully extended. The distance between the two marks is measured. This distance increases by >5 cm in the case of normal mobility and by <4 cm in the case of decreased mobility.

Involvement of sacroiliac joint

The tests mentioned below produce stress and pain in the sacroiliac joint.

- **Patrick's test** (figure of 4 test): Pain in the sacroiliac joints may be elicited either by direct pressure or by maneuvers that stress the joint, namely, Patrick's test. One leg is guided into 'figure of 4' position with the ipsilateral ankle resting across the contralateral thigh. The ipsilateral knee is then pressed downwards with one hand while providing counter pressure with the other hand on the contralateral anterior superior iliac spine.
- **FABER (flexion abduction external rotation) maneuver:** Patient lies supine while the examiner flexes and externally rotates the hip.
- **Gaenslen's maneuver:** The examiner extends the hip by letting the leg dangle off the side of the examining table.
- Occiput to wall test **(Flesch test):** Normally zero, in AnS it is increased.

Enthesitis

- Enthesitis is inflammation at the sites of tendon/ligament insertions.
- **Heel pain** due to inflammation at the **Achilles tendon** (Achilles tendinitis) and **plantar fascia** (plantar fasciitis) at calcaneal insertions is common. Like arthritis, enthesitis is also aggravated by rest and improved with activity.
- Other sites of enthesitis include superior and inferior aspects of patella, metatarsal heads and spinal ligament insertions on vertebral bodies.

Other sites

- Involvement of the thoracic spine, costovertebral joints and costosternal joints leads to chest pain, reduced expansion of chest (<5 cm) and thoracic kyphosis.
- Involvement of the cervical spine produces neck pain and a forward stoop of the neck.
- Peripheral arthritis usually occurs late and asymmetric. Involvement of hips and shoulders result in pain and limitation of movement.
- **Dactylitis (sausage digits)** is characterized by diffuse swelling of toes or fingers.

Extra-articular manifestations

See **Table 8.18**.

TABLE 8.18: Extra-articular manifestations of ankylosing spondylitis.

➢ Acute anterior uveitis (iritis) ➢ Inflammatory bowel disease ➢ Aortic insufficiency, cardiac conduction defects and heart failure ➢ Psoriasis ➢ Pulmonary fibrosis and cavitation (apical)	➢ Osteoporosis ➢ Myelopathy secondary to atlantoaxial subluxation and spinal fracture ➢ Cauda equina syndrome ➢ Amyloidosis

Investigations

Q. Describe the diagnostic work up and management of ankylosing spondylitis.

- Erythrocyte sedimentation rate (ESR) and C-reactive protein: Raised.
- Tests for rheumatoid factor (RF): Negative.
- Anti-cyclic citrullinated peptide (CCP) and antinuclear antibodies (ANAs): Negative.
- **HLA-B27: Present in >90% cases.** High sensitivity and specificity.
- **MRI and bone scan:** They can detect early sacroiliitis.

Radiographic Findings

X-ray

- **Sacroiliac joint:** The medial and lateral cortical margins of both sacroiliac joints lose definition owing to erosions. They show irregularity and loss of cortical margins (blurring of the cortical margins of the subchondral bone), erosions in the joint line, and 'pseudo-widening' of the joint space. Subsequently, it shows subchondral sclerosis, joint space narrowing and fusion, bony ankylosis reflecting complete bony replacement of the sacroiliac joints.
- **Lumbar spine:** Radiographs of the spine may show anterior '**squaring**' (loss of the normal anterior concavity of the lumbar vertebra), 'shiny corners' (subchondral sclerosis at the upper edge of the vertebral body), or even 'barreling' of one or more vertebral bodies due to erosion and sclerosis of the anterior corners of vertebrae with subsequent erosion. These are manifestations of enthesitis.
  - **Bridging syndesmophytes** are areas of calcification that follow the outermost fibers of the annulus and may also be seen in AS. Progressive ossification may lead to formation of **marginal syndesmophytes** make the diagnosis clear. They are observed as bony bridges connecting successive vertebral bodies anteriorly and laterally. In advanced disease, ossification of the anterior longitudinal ligament and facet joint fusion may also be seen. Eventually, the changes may result in a '**bamboo spine**' **(Fig. 8.6)**, so called because the multiple bridging syndesmophytes (bridging the intervertebral spaces) can mimic the appearance of bamboo.
  - Diffuse osteoporosis of spine and atlantoaxial dislocation can be seen as late feature. Erosive changes may be observed in the symphysis pubis, the ischial tuberosities and peripheral joints.

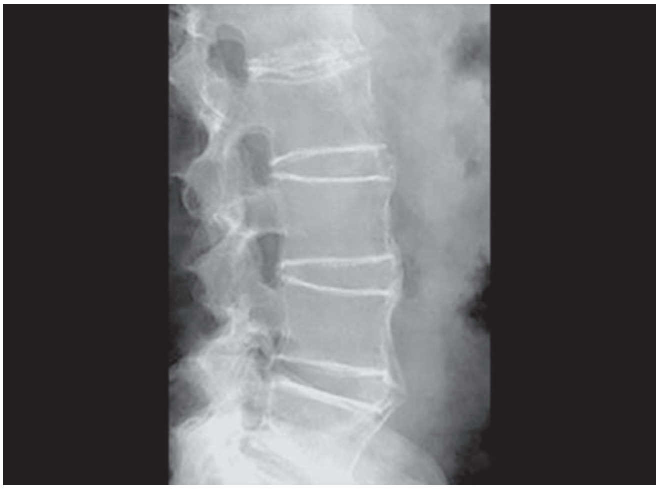

FIG. 8.6: Bamboo spine in ankylosing spondylitis.

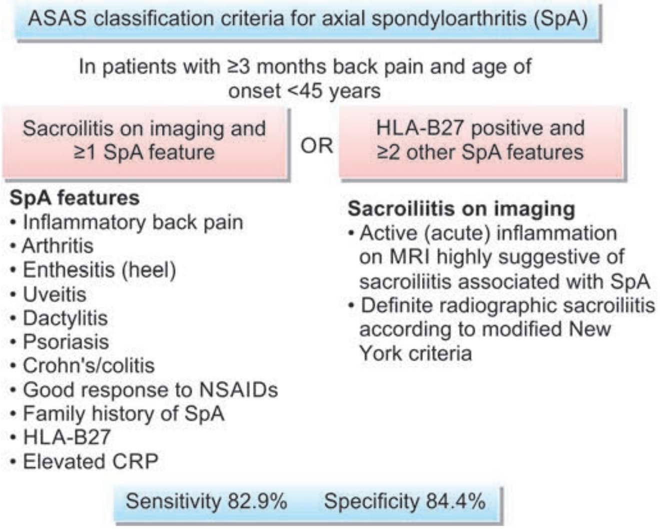
Magnetic resonance imaging (MRI)

MRI is **much more sensitive** for detection of early sacroiliitis than X-ray and can also detect inflammatory changes in the lumbar spine.

The classification and diagnostic criteria of ankylosing spondylitis **(Box 8.7)**.



ASAS classification criteria for axial spondyloarthritis (SpA)

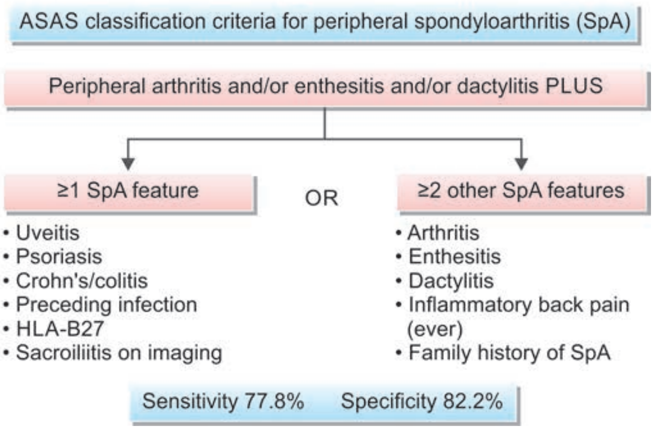
In patients with ≥3 months back pain and age of onset <45 years

Sacroilitis on imaging and ≥1 SpA feature OR HLA-B27 positive and ≥2 other SpA features

SpA features
- Inflammatory back pain
- Arthritis
- Enthesitis (heel)
- Uveitis
- Dactylitis
- Psoriasis
- Crohn's/colitis
- Good response to NSAIDs
- Family history of SpA
- HLA-B27
- Elevated CRP

Sacroiliitis on imaging
- Active (acute) inflammation on MRI highly suggestive of sacroiliitis associated with SpA
- Definite radiographic sacroiliitis according to modified New York criteria

Sensitivity 82.9% Specificity 84.4%



ASAS classification criteria for peripheral spondyloarthritis (SpA)

Peripheral arthritis and/or enthesitis and/or dactylitis PLUS

≥1 SpA feature OR ≥2 other SpA features

- Uveitis
- Psoriasis
- Crohn's/colitis
- Preceding infection
- HLA-B27
- Sacroiliitis on imaging

- Arthritis
- Enthesitis
- Dactylitis
- Inflammatory back pain (ever)
- Family history of SpA

Sensitivity 77.8% Specificity 82.2%

Box 8.7: Modified New York Criteria (1984) for ankylosing spondylitis.

Clinical criteria

- Low back pain and stiffness for >3 months that improve with exercise but are not relieved by rest
- Limitation of motion of the lumbar spine in both sagittal and frontal planes
- Limitation of chest expansion

Radiologic criteria

Sacroiliitis: Grade ≥2 bilateral *or* grade 3 or 4 unilateral

Grading

Definite AS (ankylosing spondylitis) if the radiologic criterion is associated with at least one clinical variable.

Probable ankylosing spondylitis (AS) if:

- The three clinical criteria are present
- The radiologic criterion is present without the clinical criteria

Management

- Early diagnosis is important to maintain posture and range of motion.
- Regular exercise is started with active and passive physiotherapy before syndesmophytes have formed.
- Symptomatic relief of pain and stiffness can be obtained with long-acting or slow-release NSAID or an NSAID suppository improves sleep, peripheral arthritis and enthesitis are managed with NSAIDs or local steroid injections. Indomethacin is the most effective drug and may be given up to a maximum dose of 100 mg/day. Systemic glucocorticoids have limited role.
- **Sulfasalazine and methotrexate** are useful to control effectively for peripheral arthritis but not for spinal disease.
  - Peripheral arthritis and enthesitis are managed with NSAIDs or local steroid injections. Rarely systemic corticosteroids may be necessary.

Anti-tumor necrosis factor therapy

Biologic agents, such as monoclonal antibodies to TNF-α **(infliximab, adalimumab, certolizumab, golimumab)** or the soluble TNF receptor **(etanercept)** are options for patients with active ankylosing spondylitis who are not satisfactorily responded to NSAIDs. Duration of treatment is 2–3 years.

Dosage

- Infliximab: 3–5 mg/kg body weight intravenously every 6–8 weeks.
- Etanercept: 25 mg subcutaneously twice a week initially/50 mg once weekly.
- Adalimumab: 40 mg biweekly by subcutaneous injection.
- Golimumab: 50 or 100 mg every 4 weeks, given by subcutaneous injection.

Secukinumab and ixekizumab are interleukin-17 monoclonal antibodies that have been approved for treatment of ankylosing spondylitis.

Others

- **Reconstructive surgery:** Total hip replacement is indicated in the setting of severe pain and limitation of motion
- Bisphosphonates and calcium/vitamin D replacement should be considered in axial spondyloarthritis (axSpA) patients with osteoporosis.
- Control of uveitis by local steroids.

Reactive Arthritis

Q. Describe the etiology, clinical features, diagnosis and management of reactive arthritis.

Q. Write a short note on Reiter's syndrome.

- Reactive arthritis (ReA) refers to **acute nonpurulent arthritis** (aseptic arthritis) **complicating an extra-articular infection** elsewhere in the body, most typically enteric (GIT) or urogenital (GU tract) infections.
- **Classical triad of Reiter's syndrome** is (1) **nonspecific urethritis**, (2) **conjunctivitis** and (3) **arthritis.** However, the term is no longer in common use.

Etiology

- **GIT infections:** Common enteric organisms that trigger include *Salmonella typhimurium, Shigella flexneri, Yersinia enterocolitica, Escherichia coli, Clostridum difficile*, and *Chlamydia*.
- **GUT infection:** Common urogential organisms are *Chlamydia trachomatis* or *Ureaplasma urealyticum*.
- More than 75% of ReA patients have the histocompatibility antigen HLA-B27.

Clinical Features

- **Age and gender:** Predominantly a disease of young (18–40 years) men, with a male preponderance of 15:1.
- **Constitutional symptoms** are common and include fatigue, malaise, fever, and weight loss.
- **Arthritis:** Arthritis is typically an acute, asymmetrical, lower limb (e.g. knees, ankles, midtarsal and MTP joints) arthritis and occurs 1 to 3 weeks after the GIT or GUT infection, arthritis usually persists for 3–5 months.
- **Enthesitis** is common.
- **Dactylitis** or **'sausage digit,'** is a diffuse swelling of a solitary finger or toe may also be seen. It is the result of inflammatory changes affecting the joint capsule, entheses, periarticular structures, and periosteal bone.
- Sacroiliitis may be seen in 25% patients.
- **Extra-articular features**
    - **Urogenital lesions:** Urethritis and prostatitis in males, cervicitis or salpingitis in females.
    - **Mucocutaneous lesions:** *Circinate balanitis* (a painless erythematous lesion of the glans penis), *keratoderma blennorrhagica* (hyperkeratotic lesions on the palms of the hands or the soles of the feet) and nail dystrophy.
    - **Ocular disease:** Common and includes conjunctivitis, anterior uveitis and acute iritis.
    - **Others:** Cardiac conduction defects, aortic regurgitation, central or peripheral nervous system lesions, and pleuropulmonary infiltrates.
- Usually a self-limiting course of 3–12 months. About 50% of patients develop recurrent bouts of arthritis and 15–30% develop chronic arthritis or sacroiliitis.

Investigations

- Erythrocyte sedimentation rate (**ESR**) and acute-phase reactants: Usually **raised**.
- **Peripheral blood:** Anemia and polymorphonuclear leukocytosis.
- **Synovial fluid:** Characteristic synovial fluid is **leukocyte-rich** (>2000 white blood cells/mL with a predominance of neutrophils) and may contain multinucleated macrophages (Reiter's cells).
- **HLA-B27: Positive** in more than 75% of cases.
- Serum tests for rheumatoid factor and antinuclear antibodies: Negative.
- **Urethritis:** Confirmed in the 'two-glass test' by demonstration of mucoid threads in the first-void specimen that clears in the second specimen.

Radiological features

- Shows periarticular osteoporosis, joint space narrowing and proliferative erosions in chronic or recurrent disease.
- Periostitis, especially of metatarsals, phalanges and pelvis, and large, fluffy calcaneal spurs at the insertion of the plantar fascia. Sacroiliitis (less common than ankylosing spondylitis) is often asymmetrical and sometimes unilateral. Syndesmophytes (Jug Handle) are predominantly coarse and asymmetrical, often extending beyond the contours of the annulus ('non-marginal').

Management

- **Acute attack:**
    - Treated with rest, oral NSAIDs and analgesics. Indomethacin, 75–150 mg/d in divided doses, is the initial treatment of choice.
    - Intra-articular or local steroid injections and rarely systemic steroids in severe cases.
- **Non-specific chlamydial urethritis:** Treated with **doxycycline or ciprofloxacin** or a single dose of azithromycin course.
- No role of antibiotics in reactive spondyloarthropathy secondary to enteric infections.
- **Sulfasalazine, azathioprine and methotrexate** may be useful in patients with disabling relapsing and remitting arthritis.
- **DMARDs:** For patients with persistent marked symptoms, recurrent arthritis or severe keratoderma blennorrhagica.
- Anterior uveitis is a medical emergency and treated by topical, subconjunctival or systemic corticosteroids.
- **TNF-α blocking agents** are the drugs of next choice in severe and persistent disease.

Psoriatic Arthritis

Q. Write short note on psoriatic arthritis.

- Psoriatic arthritis (PsA) is a seronegative inflammatory arthritis that characteristically occurs in patient with psoriasis, a past or family history of psoriasis or with characteristic nail changes.
- Occurs in about 7–20% of patients of psoriasis.

Types: Wright and Moll described five patterns of psoriatic arthritis **(Box 8.8)**

Newer pattern of psoriatic arthritis is described in **HIV patients**.

Box 8.8: Patterns of psoriatic arthritis.

- Asymmetric inflammatory oligoarthritis
- Symmetric polyarthritis similar to RA (rheumatoid arthritis)
- Arthritis of the DIP (distal interphalangeal) joints
- Spondyloarthropathy (sacroiliitis and spondylitis)
- Arthritis mutilans

Clinical Features

It presents with pain and swelling affected joints and enthesitis. Psoriasis precedes arthritis by an average of 8 to 10 years in ~70% patients. Arthritis precedes psoriasis in ~10% to 15% patients (particularly in childhood). Simultaneous onset of PsA and psoriasis occurs in ~15% patients.

- **Asymmetrical inflammatory oligoarthritis:** Most characteristically occur in the hands and feet, when synovitis is associated with tenosynovitis, enthesitis and inflammation of intervening tissue resulting in a **'sausage-shaped digit' or dactylitis**. Usually, less than four joints are involved (oligoarthritis).
- **Symmetrical polyarthritis:** It is more common in women and may strongly resemble RA.
- **Arthritis of the DIP joints:** Uncommon and affects men more than women. It involves finger DIP joints and surrounding periarticular tissues, and is accompanied by nail dystrophy.
- **Psoriatic spondylitis:** Presents similar to AS but with less severe involvement. It is typically unilateral or asymmetric in severity.
- **Arthritis mutilans** is a severe, deforming erosive arthritis accompanied by prominent cartilage and bone destruction results in marked instability of fingers and toes. The encasing skin appears invaginated and 'telescoped' and the finger can be pulled back to its original length.
- ***Enthesitis and tenosynovitis are common.***
- **Skin lesions:** Characteristic skin lesion of psoriasis may be present.
- **Nail changes (Fig. 8.7):** Psoriatic nail dystrophy, onycholysis, pitting, and hyperkeratosis observed in nearly 80% patients with arthritis.
- **Uveitis:** Unilateral or bilateral and is generally chronic.

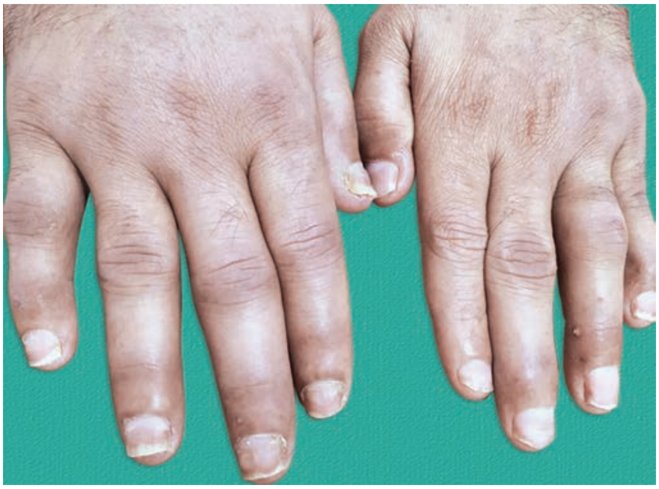


FIG. 8.7: Sausage digits in psoriatic arthritis and psoriatic nails.

Q. Differentiate psoriatic arthritis from rheumatoid arthritis (Table 8.19).

Diagnosis

- Acute phase reactants (ESR and CRP): Raised in active disease.
- **Rheumatoid factor and antinuclear antibodies:** Negative.
- **Radiological findings:** May be normal or show erosive change with joint space narrowing similar to those of RA, but osteoporosis is relatively less common. Distal interphalangeal joints may show **'pencil-in-cup' changes (Fig. 8.8)** because of marked resorption of bone. Other findings include enthesitis with periosteal reaction, sacroiliitis and spondylitis.
- MRI and ultrasound with power Doppler are used to detect synovial inflammation and inflammation at the enthuses (enthesitis). *Classification of Psoriatic Arthritis (CASPAR)* criteria is used for diagnosis which include *skin lesions, nail changes, negative RF, dactylitis and juxta-articular bone formation*—3 out of 5 need to be present.

TABLE 8.19: Distinguishing clinical features of psoriatic arthritis from rheumatoid arthritis.

	Psoriatic arthritis	***Rheumatoid arthritis***
Psoriasis	+	-
Symmetric involvement	+	++
Asymmetric involvement	++	+
Enthesopathy	+	-
Dactylitis	+	-
Nail dystrophy, psoriatic skin lesions	+	-
HIV association	+	-
DIP (distal interphalangeal) involvement	+	-
Inflammatory LBA (low backache)	+	-
Sacroiliac joint involvement	+	-

(+: Present; –: Absent)

Management

- NSAIDs and analgesics may be sufficient to control symptoms in mild disease.
- Local synovitis may be treated by intra-articular corticosteroid injections.
- DMARDs for persistent synovitis unresponsive to conservative treatment. Sulfasalazine or methotrexate slows the development of joint damage.
- Anti-TNF-α agents (e.g. etanercept, golimumab, infliximab and adalimumab) should be considered for patients with active synovitis who respond inadequately to standard DMARDs.
- **Secukinumab and Ixekizumab** block IL-17 and are effective for treating both skin and musculoskeletal manifestations of PsA.
- **Tofacitinib** demonstrated efficacy in treating PsA with similar safety profile as in rheumatoid arthritis
- Hydroxychloroquine must be avoided as it can cause exfoliative skin reactions.
- **Alefacept** is a fusion protein of soluble lymphocyte function antigen 3 with Fc fragments of IgG1. It is used for moderate-to-severe psoriasis and associated arthritis.
- **Apremilast,** an inhibitor of phosphodiesterase 4, also treats both psoriasis and PsA, but response is not as great as other biologicals.

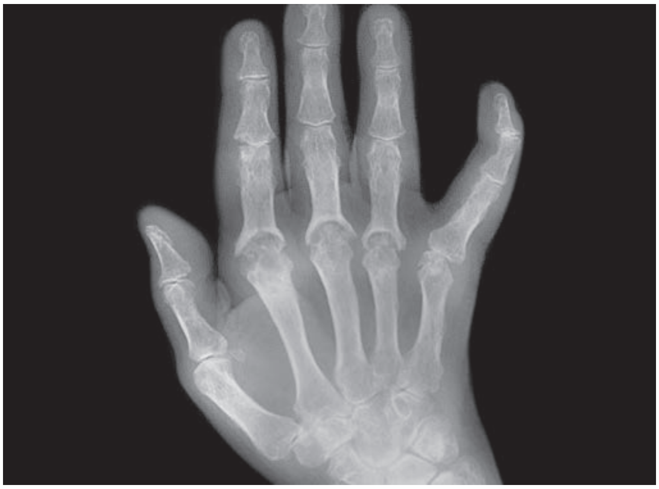

FIG. 8.8: X-ray of hand shows 'pencil-in-cup' appearance in psoriatic arthritis.

Enteropathic Arthritis

Q. Write short note on spondyloarthropathy associated with inflammatory bowel disease.

Also called as enteropathic arthritis associated with inflammatory bowel disease (ulcerative colitis and Crohn's disease). An acute inflammatory oligoarthritis occurs in 10–20% of patients with inflammatory bowel disease (IBD).

More often in patients with Crohn's disease than in those with ulcerative colitis.

Occurs more commonly in men than in women (3:1).

Clinical Features

Peripheral arthritis

- The arthritis is asymmetrical, inflammatory, nonerosive polyarthritis and mainly involves lower-limb joints (knees, ankles, hips).
- The clinical activity of the peripheral arthritis parallels the activity of the gut inflammation. Effective treatment of the GI disease usually controls the joint disease as well.
- It is not associated with HLA-B27 and follows a transient course.

Sacroiliitis

- It is clinically and radiologically similar to classic AS.
- It can manifest before or after the onset of IBD and there is no correlation between activity of the spondylitis and bowel disease.
- HLA-B27 is found in 50% of patients and it follows a chronic course.

Others: Enthesitis, dactylitis and extra-articular manifestations of IBD.

Differences between inflammatory and mechanical low back pain (LBP) (Table 8.20).

Treatment

- NSAIDs to be used cautiously because they may worsen diarrhea.
- Monoarthritis is treated by intra-articular corticosteroids.
- Sulfasalazine more effective as it may help both bowel and joint disease. Azathioprine and methotrexate may also be used.
- TNF-α blocking drug infliximab used for IBD can help the arthritis.

Q. Describe the clinical clues to differentiate inflammatory low back pain of ankylosing spondylitis from mechanical low back pain.

Q. Differentiate between inflammatory versus mechanical back pain.

ADULT-ONSET STILL'S DISEASE (AOSD)

Q. Discuss the clinical features of adult-onset Still's disease.

AOSD is a rare inflammatory multisystem disease occurring in adults presenting as fever (quotidian/double quotidian), rash, arthritis, sore throat, hepatosplenomegaly and serositis (pleural and pericardial effusion).

The rash is classically evanescent, salmon-colored, macular or maculopapular which is usually nonpruritic and occurs with the fever. Arthritis and arthralgia mostly involve the knee, wrist and the ankle. Myalgia is seen in more than 50 percent of the cases. Macrophage activation syndrome, a rare and fatal complication of Adult-onset Still's disease characterized by leukopenia, hypertriglyceridemia, transaminitis and intravascular coagulation.

TABLE 8.20: Differences between inflammatory and mechanical low back pain (LBP).

Features	*Inflammatory LBP*	*Mechanical LBP*
Age at onset	< 40 years	Any age
Type of onset	Insidious	Acute
Symptom duration	>3 months	<4 weeks
Morning stiffness	>60 minutes	<30 minutes
Nocturnal pain	Frequent	Absent
Effect of exercise	Improvement	Exacerbation
Sacroiliac joint tenderness	Frequent	Absent
Back mobility	Loss in all planes	Abnormal flexion
Chest expansion	Often decreased	Normal
Neurologic deficits	Unusual	Possible

Diagnosis

- Adult-onset Still's disease (ASOD) is primarily a diagnosis of exclusion.
- Neutrophilia, thrombocytosis, raised ESR, CRP are present. Increased LDH and liver enzymes are seen.
- Marked elevation of ferritin (>3000 mg/mL) found in more than 70% of patients. Reduced level (<20%) of glycosylated fraction of ferritin is a more useful marker.
- RF and ANA are negative.
- **Yamaguchi criteria** is the accepted diagnostic criteria.

  Major criteria
  - Fever >39°C for >7 days
  - Arthralgias or arthritis ≥2 weeks
  - Characteristic rash
  - Leukocytosis (≥10,000/µL with ≥80% neutrophils)

  Minor criteria
  - Sore throat
  - Lymphadenopathy
  - Hepatomegaly or splenomegaly
  - Abnormal aminotransferase
  - Negative rheumatoid factor and antinuclear antibody

Treatment

- Often a self-limited disease, rarely can have an intermittent flares and chronic articular form.
- NSAIDs and glucocorticoids can be given to reduce systemic inflammation.
- DMARDs like methotrexate may be used as steroid sparing agents.
- Anti-TNF alpha antagonist and IL-1 antagonist (Anakinra) and cyclosporine can be used for patients presenting with macrophage activation syndrome.

JUVENILE IDIOPATHIC ARTHRITIS/JUVENILE RHEUMATOID ARTHRITIS

- Formerly called Still's disease.
- Onset is before 16 years of age, manifestations persist for at least 6 weeks, and the etiology is unknown.
- JIA can manifest with following clinical types:
  - Systemic arthritis associated with fever, rash, lymphadenopathy and organomegaly
  - Polyarthritis, involvement of 4 or more joint areas. RF may be positive or negative
  - Oligoarthritis, involving 4 or less joint areas
  - Enthesitis related arthritis
  - Psoriatic arthritis
  - Undifferentiated arthritis
- Other features include polyserositis and macrophage activation syndrome.

- Mild to disease responds to NSAIDs and steroids
- Biologic agents, such as anakinra, canakinumab, or tocilizumab are useful in severe disease and systemic complications.

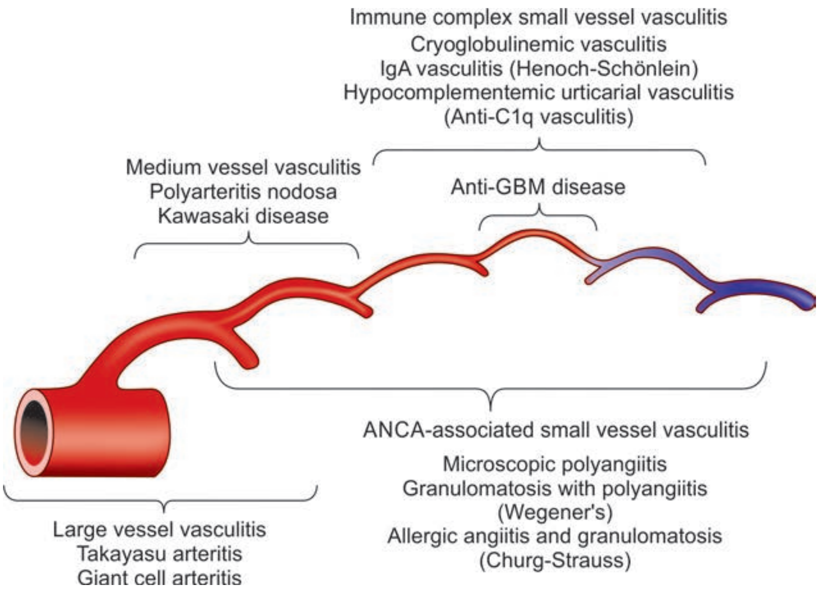
VASCULITIS

Q. Define and classify vasculitis.

Definition: Vasculitis refers to a heterogeneous group of disorders that is characterized by destructive inflammation of blood vessel walls. The lumen of the inflamed blood vessels is liable to occlude or rupture or develop a thrombus, and this is associated with ischemia of the tissues supplied by the involved vessel.

Classification (Fig. 8.9)

Vasculitis may involve a single organ (e.g. skin), or it may involve several organ systems. One of the basis for classifying the vasculitides is the size of the predominant blood vessels involved **(Box 8.9)**.



Immune complex small vessel vasculitis
Cryoglobulinemic vasculitis
IgA vasculitis (Henoch-Schönlein)
Hypocomplementemic urticarial vasculitis
(Anti-C1q vasculitis)
Medium vessel vasculitis
Polyarteritis nodosa
Kawasaki disease
Anti-GBM disease
ANCA-associated small vessel vasculitis
Microscopic polyangiitis
Granulomatosis with polyangiitis
(Wegener's)
Allergic angiitis and granulomatosis
(Churg-Strauss)
Large vessel vasculitis
Takayasu arteritis
Giant cell arteritis

FIG. 8.9: Classification of vasculitis.

Clinical Manifestations

Q. Write short essay/note on clinical features of vasculitis.

Constitutional symptoms: Fever, weight loss, malaise, arthralgias/arthritis (common to vasculitides of all vessel sizes). Typical clinical manifestations of large, medium, and small vessel vasculitis are presented in **Table 8.21** and vasculitis associated with granulomatous inflammation is listed in **Table 8.22 and Flowchart 8.4**.

Box 8.9: Classification of the primary vasculitides according to size of predominant blood vessels involved (Chapel Hill Consensus Conference).

Predominantly large-vessel (aorta and its major tributaries) vasculitis

- Giant cell arteritis
- Takayasu arteritis
- Cogan syndrome

Predominantly medium-vessel (medium and small-sized arteries and arterioles) vasculitis

- Polyarteritis nodosa
- Primary central nervous system disease
- Buerger disease

Predominantly small-vessel (small arteries, arterioles, venules and capillaries) vasculitis

- ANCA-associated small-vessel vasculitis
  - Granulomatosis with polyangiitis (Wegener granulomatosis)
  - Microscopic polyangiitis
  - Churg-Strauss syndrome (allergic angiitis and granulomatosis)
  - Drug-induced ANCA-associated vasculitis
- Immune complex mediated
  - Cutaneous leukocytoclastic angiitis ('hypersensitivity' vasculitis)
  - Henoch-Schönlein purpura
  - Urticarial vasculitis

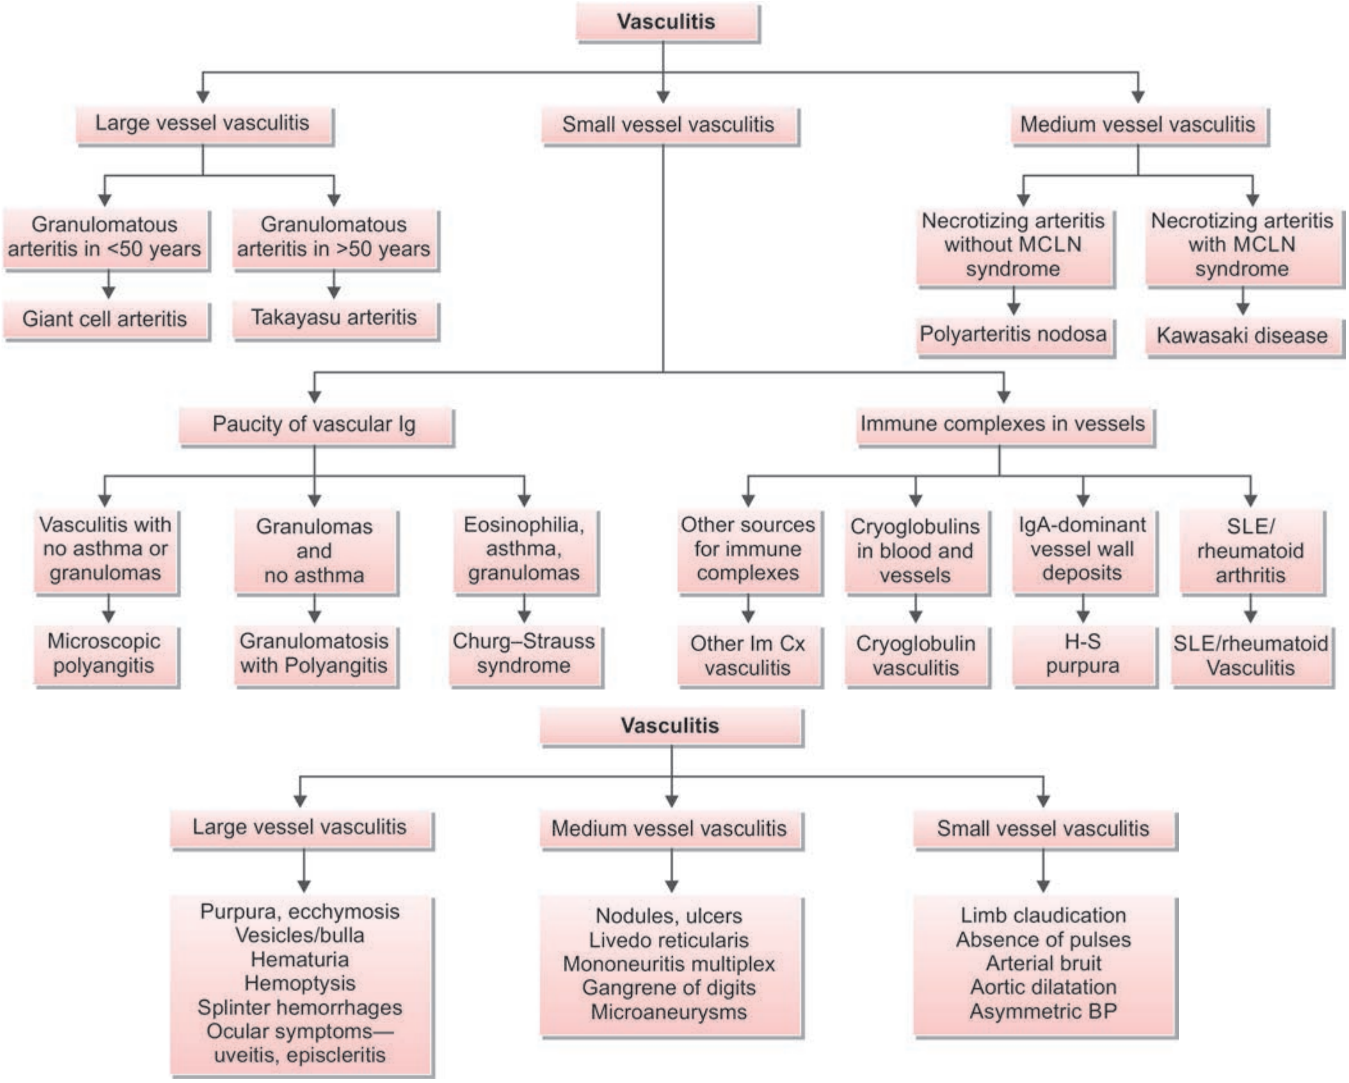
TABLE 8.21: Typical clinical manifestations of vasculitis.

Large	*Medium*	*Small*
➢ Limb claudication ➢ Asymmetric blood pressure ➢ Absence of pulses ➢ Bruits ➢ Aortic dilation ➢ Renovascular hypertension	➢ Cutaneous ➢ Nodules ➢ Ulcers ➢ Livedo reticularis ➢ Digital gangrene ➢ Mononeuritis multiplex ➢ Microaneurysms ➢ Renovascular hypertension	➢ Purpura ➢ Vesiculobullous lesions ➢ Urticaria ➢ Glomerulonephritis ➢ Alveolar hemorrhage ➢ Cutaneous extravascular necrotizing granulomas ➢ Splinter hemorrhages ➢ Uveitis/episcleritis/ scleritis

TABLE 8.22: Vasculitis associated with granulomatous inflammation.

➢ Giant cell arteritis ➢ Takayasu's arteritis ➢ Cogan's syndrome ➢ Wegener's granulomatosis (granulomatosis with polyangiitis)	➢ Churg-Strauss syndrome ➢ Primary angiitis of the central nervous system ➢ Buerger's disease ➢ Rheumatoid vasculitis

FLOWCHART 8.4: Clinical features of vasculitis.



Vasculitis
Large vessel vasculitis
Small vessel vasculitis
Medium vessel vasculitis
Granulomatous arteritis in <50 years
Granulomatous arteritis in >50 years
Giant cell arteritis
Takayasu arteritis
Necrotizing arteritis without MCLN syndrome
Necrotizing arteritis with MCLN syndrome
Polyarteritis nodosa
Kawasaki disease
Paucity of vascular Ig
Immune complexes in vessels
Vasculitis with no asthma or granulomas
Granulomas and no asthma
Eosinophilia, asthma, granulomas
Other sources for immune complexes
Cryoglobulins in blood and vessels
IgA-dominant vessel wall deposits
SLE/ rheumatoid arthritis
Microscopic polyangitis
Granulomatosis with Polyangitis
Churg–Strauss syndrome
Other Im Cx vasculitis
Cryoglobulin vasculitis
H-S purpura
SLE/rheumatoid Vasculitis
Vasculitis
Large vessel vasculitis
Medium vessel vasculitis
Small vessel vasculitis
Purpura, ecchymosis
Vesicles/bulla
Hematuria
Hemoptysis
Splinter hemorrhages
Ocular symptoms—uveitis, episcleritis
Nodules, ulcers
Livedo reticularis
Mononeuritis multiplex
Gangrene of digits
Microaneurysms
Limb claudication
Absence of pulses
Arterial bruit
Aortic dilatation
Asymmetric BP

(MCLN: Mucocutaneous lymph node; Im Cx: Immune complex; H-S: Henoch-Schönlein)

Investigations in Suspected Vasculitis

- **Tests suggesting systemic inflammation:**
  - Complete blood count—anemia of chronic disease and thrombocytosis. White blood cell count—neutrophilia or eosinophilia.
  - Erythrocyte sedimentation rate >100 mm/hour and C-reactive protein >10 mg/dL in the absence of bacterial infection and widespread cancer should suggest vasculitis.
  - Low albumin is a negative acute-phase reactant and decreases with systemic inflammation.
- **Tests suggesting organ involvement:**
  - Creatinine and urinalysis
  - Liver-associated enzymes—if extremely elevated, consider hepatitis B/C
  - Creatine kinase
  - Lumbar puncture with cerebrospinal fluid analysis—if CNS symptoms
  - Stool for occult blood
  - Chest radiograph
  - Electromyography (EMG) and nerve conduction velocity (NCV)—if neuropathy symptoms
  - Brain magnetic resonance imaging or an abdominal computed tomography (CT) scan—if symptoms suggest involvement.

- **Tests suggesting immune complex formation and/or deposition:**
  - RF and ANA—should not be positive in primary systemic vasculitis. If RF is positive, consider cryoglobulinemia and SBE. If ANA is positive, consider SLE or Sjögren's syndrome.
  - Anti-C1q—if history of urticarial vasculitis.
  - Cryoglobulins—if positive, rule out hepatitis C.
  - Complement levels—C3/C4 are low in cryoglobulinemia, hypocomplemententemic urticarial vasculitis, and SLE.
- **Tests suggesting ANCA-related vasculitis:**
  - c-ANCA—usually GPA; sometimes MPA.
  - p-ANCA—consider MPA and EGPA; sometimes GPA.
  - Eosinophil count/IgE level if suspect EGPA.
- **Tests suggesting etiology:**
  - Blood cultures—rule out SBE.
  - Infectious serologies—Hep BsAg (PAN), hepatitis C (cryoglobulinemia), parvovirus IgM (GPA and PAN), herpes (IgM and PCR), cytomegalovirus (IgM and PCR), Epstein–Barr virus (IgM and PCR), HIV (any vasculitis).
  - Antiglomerular basement membrane antibody—any patient with pulmonary–renal syndrome.
  - Serum protein electrophoresis—rule out myeloma.
  - Cerebrospinal fluid studies—herpes, varicella-zoster virus (VZV DNA and anti-VZV antibody).

Giant Cell Arteritis (GCA)

Q. Write short essay/note on temporal arteritis, cranial arteritis or giant cell arteritis.

Giant cell arteritis (temporal arteritis, Horton disease or cranial arteritis) is **inflammatory granulomatous arteritis** of large and medium sized **arteries in the head and neck**. It can involve aorta and its primary and secondary branches.

- **Age and gender:** It is a disease of the elderly and average age at onset is 70. It is extremely rare below 60 years of age. Female to male ratio is about 3:1.
- **Vessels involved:** One or more branches of the carotid artery (e.g. temporal artery, occipital, ophthalmic, posterior ciliary arteries and vertebral arteries). It can involve multiple arteries, aorta and its branches.

Clinical Features

- **Onset** may be gradual or sudden.
- **Systemic manifestations:** Severe malaise, tiredness, **fever, anemia, fatigue** and weight loss.
- **Severe headache:** Most severe and often localized along the course of the superficial temporal artery or occipital region. Arteritis often occurs in the carotid/temporal arteries. On palpation, **the involved artery is tender, thickened** and cord-like or **nodular.** It may be accompanied by tenderness of the scalp or of the temple.
- **Jaw claudication:** When chewing, eating or talking, due to ischemia of the masseter muscles.
- **Visual symptoms:** These include loss of visual acuity, reduced color perception and pupillary defects. It can even present as **sudden blindness** in one eye due to occlusion of the posterior ciliary artery.
- **Neurological manifestations:** It occurs in about 30% of patients and includes transient ischemic attacks, brainstem infarcts and hemiparesis.

Investigation

- **Normochromic, normocytic anemia.**
- **ESR** is **raised** (50–120 mm/h) and the **CRP very high.**
- **Temporal artery biopsy** from the affected side is the **definitive diagnostic test**. Characteristic biopsy findings are fragmentation of the internal elastic lamina with necrosis of the media, mixed inflammatory cell infiltrate and granulomatous inflammation of the intima and media with giant cells.
- **Color Doppler ultrasound or arteriography:** It may be used for guiding biopsy. Duplex ultrasonography can detect the characteristic appearance.

Treatment

Corticosteroids are the treatment of choice and should be commenced urgently in suspected giant cell arteritis to prevent the risk of visual loss. It responds dramatically within 24–48 hours of starting corticosteroids. Prednisolone is given at a doseof 40–60 mg/day. NSAIDs should not be used. Tocilizumab and methotrexate have been used as steroid sparing agents.

Polymyalgia Rheumatica (PMR)

Q. Write short note on polymyalgia rheumatica.

PMR is characterized by pain, aching, and stiffness in the muscles of the neck, shoulders, and hip-girdle area that are usually much worse in the morning. PMR is closely associated with GCA (giant cell arteritis).

Association between PMR and GCA: These two disorders frequently occur together. In fact, PMR has been noted in 40% to 60% of patients with GCA and may be the initial symptom in 20% of cases. Conversely, GCA occurs in at least 15% of patients with PMR. The association between PMR and GCA is so strong that many have speculated that they represent the same disease but with differing severity.

Criteria for the Diagnosis of PMR (Box 8.10)

Box 8.10: Criteria for the diagnosis of PMR (polymyalgia rheumatica).

- Age >50 years
- Aching and stiffness for at least 1 month, affecting at least two of the three areas (i.e. shoulders, neck, and pelvic girdle)
- Morning stiffness lasting at least 1 hour
- ESR >40 mm/hour
- Exclusion of other diseases except GCA (giant cell arteritis)
- Rapid response to prednisone (20 mg/day)
- All of the above criteria must be met to diagnose PMR

Treatment

Corticosteroids: Prednisolone (12.5 to 25 mg) is rapidly effective. Symptoms are relieved within 48–72 hours and the ESR normalizes after 7–10 days. Methotrexate (MTX) 7.5 to 10 mg/week with GCs, as a steroid sparing agent.

Classic Polyarteritis Nodosa (PAN)

Q. Describe the clinical features, diagnosis and management of classic polyarteritis nodosa (PAN).

Definition: Polyarteritis nodosa (Kussmaul disease) is also called classic polyarteritis nodosa is a **systemic, necrotizing vasculitis of small and medium-sized muscular arteries** that **spares the smallest blood vessels** (e.g. arterioles, venules or capillaries). It characteristically involves the **renal and visceral arteries** and is not associated with glomerulonephritis.

Two additional features that distinguish PAN from other forms of systemic vasculitis are:

1. **Confinement of the disease to the arterial rather than the venous circulation.**
2. **Absence of granulomatous inflammation**.

Organ systems involved: Commonly involves **skin, kidneys, heart, liver, and gastrointestinal tract**. **PAN does not involve pulmonary arteries.**

About 30% of patients with PAN have **chronic hepatitis B** with HBsAg-HbsAb complexes in affected vessels.

Clinical Features

- Age and gender: Peak incidence between **40 to 50 years of age**. Predominantly affects middle aged males (M:F = 2:1).
- **Subacute onset** of **constitutional vague symptoms** such as fever, weight loss, weakness, malaise and arthralgias are present in >50% of cases. Others include testicular pain or tenderness, mononeuritis multiplex, and intestinal angina (postprandial pain caused by the involvement of mesenteric vessels). Renal involvement produces renal insufficiency and hypertension. Cutaneous manifestations include erythema nodosum, purpura, livedo reticularis, and ulcers.
- **Absence of pulmonary artery involvement** helps distinguish PAN from most cases of vasculitis. However bronchial arteries may be involved.

Diagnosis

- Anemia, thrombocytosis, and raised acute phase reactants.
- **Hepatitis B surface antigen (HBsAg):** It may be positive.
- p-ANCA: Present in about 20% of cases.
- **Arteriograms:** Demonstrates **aneurysms of small and medium-sized arteries** in the kidney, liver, and visceral vasculature (**Rosary bead sign**).
- **Biopsy:** Presence of characteristic findings of **focal and segmental transmural necrotizing vasculitis** of involved organ confirms the diagnosis. Biopsy of symptomatic organs such as nodular skin lesions, painful testes, and nerve/muscle reveals vasculitis. Microscopy shows destruction of the blood vessel wall by inflammatory cells, accompanied by **fibrinoid necrosis**.

Treatment

- **Glucocorticoids and cytotoxic agents:** In idiopathic PAN, remissions or cures is achieved by high doses of glucocorticoids alone (60 mg/day for 1 week followed by tapering). Cyclophosphamide, mycophenolate, rituximab and azathioprine are indicated when PAN is refractory to corticosteroids or when there is serious involvement of major organs.
- PAN with hepatitis B: Antiviral therapy used in combination with glucocorticoids and plasma exchange.

Microscopic Polyangiitis

Q. Write short note on microscopic polyangiitis.

Definition: Microscopic polyangiitis (MPA) is the most common **ANCA-associated necrotizing vasculitis** with **few or no immune complexes** in the involved vessels. It affects **small vessels** (capillaries, venules or arterioles).

Clinical Features

- **Age and gender:** Most common age of onset is 40–60 years. More common in males than females.
- Microscopic polyangiitis is the most common cause of the **pulmonary-renal syndrome,** i.e. alveolar hemorrhage and glomerulonephritis. Alveolar hemorrhage associated with hemoptysis and respiratory compromise.
- The five most common clinical manifestations of MPA are: (1) **glomerulonephritis** (~80% of patients), (2) **weight loss** (>70%), (3) **mononeuritis multiplex** (60%), (4) **fever** (55%), and (5) a variety of **cutaneous findings-**cutaneous vasculitis (>60%).
- **Other features:** Migratory arthralgias or arthritis (either pauciarticular or polyarticular), **palpable purpura,** sometimes with skin ulcerations, nodules, livedo reticularis, and digital gangrene may be seen.

Diagnosis

p-ANCA is positive in most patients, although c-ANCA may also be present in 40% cases.

Treatment

- **Glucocorticoids in combination with either rituximab or cyclophosphamide:** It is the cornerstone of treatment regimens, because most patients with MPA have major organ involvement such as glomerulonephritis, alveolar hemorrhage, or vasculitic neuropathy. Cyclophosphamide may be administered on either a daily or intermittent basis.
- **'Pulse' methylprednisolone** (1 g/d for 3 days) may be considered for patients with severe organ involvement at diagnosis.
- In severe cases (e.g. renal failure or diffuse alveolar hemorrhage), additional use of plasmapheresis and IV immunoglobulins is beneficial.
- Other treatment regimens includes mycofenolate, methotrexate, azathioprine and intravenous immunoglobulin.

Churg-Strauss Syndrome

Q. **Write short essay/note on Churg-Strauss syndrome/Eosinophilic granulomatosis with polyangiitis (EGPA).**

- Churg-Strauss syndrome (CSS) or *eosinophilic granulomatosis with polyangiitis.* It is a rare syndrome that affects small to medium-sized arteries and veins of multiple organ systems.
- **Hallmarks:** It is characterized by **asthma, peripheral and tissue eosinophilia, extravascular granuloma** formation, and **systemic vasculitis.**

Classic Clinical Features

See **Box 8.11**.

Box 8.11: Classic clinical features of Churg-Strauss syndrome.

- Allergic rhinitis and nasal polyposis (75%)
- Asthma (90%)
- Peripheral eosinophilia (10–60% of all circulating leukocytes)
- Fleeting pulmonary infiltrates and occasional alveolar hemorrhage
- Cutaneous nodules, GI bleed, eosinophilic gastroenteritis
- Acute renal insufficiency, acute glomerulonephritis, mononeuritis multiplex, venous thromboembolism, and stroke
- Coronary arteritis pericarditis, rhythm abnormalities myocarditis and heart failure

Investigations

- Striking **eosinophilia** >10% (>1000 cells/μL) in peripheral blood.
- Raised ESR fibrinogen, or α_2-globulins and CRP. Increased IgE levels.
- Urine: RBC casts and proteinuria.
- Positive antinuclear cytoplasmic antibodies against myeloperoxidase (**p-ANCA**) in ~48% of cases.
- Chest X-ray: May show infiltrates and pleural effusion.
- Biopsy: Three histologic criteria for the diagnosis: (1) the presence of necrotizing vasculitis, (2) tissue infiltration by eosinophils, and (3) extravascular granuloma.

Treatment

- High-dose steroids and cyclophosphamide, followed by maintenance therapy with low-dose steroids. Some cases may require addition of cyclophosphamide, mycophenolate and leflunomide
- In severe cases, anti-TNF-α agents like infliximab and etanercept are used
- Anti-interleukin (IL)-5 monoclonal antibodies (mepolizumab, reslizumab) and an anti-IL-5 receptor antibody (benralizumab) are approved for use in severe asthma

Granulomatosis with Polyangiitis (Wegener's Granulomatosis)

Q. **Write short essay on clinical features, diagnosis and treatment of granulomatosis with polyangiitis (Wegener's granulomatosis).**

Definition: Granulomatosis with polyangiitis is a distinct clinicopathologic entity characterized by **necrotizing vasculitis**, which involves the **upper respiratory tract**, the **lungs**, and the **kidneys.**

It is one of the most common forms of systemic vasculitis. It involves small to medium-sized blood vessels. It affects both the arterial and venous circulations.

Clinical Features

- **Age and gender:** It usually presents during **fourth to fifth decade**. **Males** are affected more often than females.
- **Nasal involvement:** Found in about 90% of patients. These include nasal crusting, epistaxis (bleeding), paranasal sinus pain, sinusitis, nasal mucosal ulceration and obstruction. Inflammation of nasal cartilage may lead to nasal septal perforation and collapse of the nasal bridge ('saddle nose' deformity). Erosive sinus disease and subglottic stenosis (narrowing of the trachea due to inflammation just below the vocal cords) are highly characteristic of granulomatosis with polyangiitis.
- **Lesions in the mouth:** Two classic mouth lesions are **gum inflammation** ('strawberry gums') and **tongue ulcers**.
- **Deafness** both conductive and sensorineural hearing loss are typical of the disease and **proptosis** due to inflammation of the retro-orbital tissue, diplopia due to entrapment of the extra-ocular muscles, and loss of vision due to optic nerve compression may occur.
- **Lung involvement** may produce cough, hemoptysis (due to alveolar hemorrhage) and dyspnea.
- **Renal involvement** occurs in the form of rapidly progressive glomerulonephritis, resulting in proteinuria, hematuria, red blood cell casts in the urine and renal failure.
- **Other manifestations:** These include palpable purpura, conjunctivitis, episcleritis, scleritis, cranial neuritis and mononeuritis multiplex.

Diagnosis

- **ESR: Markedly elevated**.
- **Non-specific abnormalities:** These include mild anemia, leukocytosis and mild hypergammaglobulinemia (particularly of the IgA class). Complement levels will be normal or elevated.
- **Serum antiproteinase-3 ANCA** (c-ANCA): **Positive** in about 90% of patients.
- **Chest radiograph:** It may show pulmonary infiltrates and **nodules that may cavitate.**
- **Imaging** of the upper airways or chest with MRI: It can be useful in localizing abnormalities.
- **Lung biopsy:** Used for confirmation of the diagnosis. It shows the characteristic necrotizing granulomatous vasculitis.
- **Renal biopsy:** It may show a segmental necrotizing crescentic glomerulonephritis, with no immunoglobulin deposition ('pauci-immune').

Treatment: Treatment is similar to that for microscopic polyangiitis.

Behçet's Disease/Syndrome

Q. Describe the symptoms, diagnosis and treatment of Behçet's disease.

Behçet's syndrome is characterized by triad of (1) **recurrent episodes of oral/mouth ulcers, (2) genital ulcers, and (3) eye inflammation (i.e. iritis).**

Pathologic process is a vasculitis (leukocytoclastic) that may affect small, medium, and large vessels in either the venous or the arterial circulation in any organ.

Box 8.12: Diagnostic criteria for Behçet's syndrome.

One required manifestation

Recurrent oral ulceration: Aphthous or herpetiform, at least three times in 12 months, usually deep and multiple, and last for 10–30 days. This is the cardinal clinical feature.

plus

At least two of the following:

- Recurrent genital ulceration occurs in 60–80% of cases.
- Characteristic eye lesions: Anterior or posterior uveitis or retinal vasculitis or cells in vitreous on slit-lamp examination.
- Characteristic skin lesions: Erythema nodosum, pseudofolliculitis, papulopustular lesions and acneiform nodules.
- Positive pathergy test.

Clinical Features

Diagnostic criteria: Diagnostic criteria of International Study Group for Behçet's syndrome is presented in **Box 8.12**. However, the spectrum of Behçet's syndrome consists of many manifestations (e.g. neurological involvement seen in 5% of patients, recurrent vascular thrombosis) that are not included in these criteria. Patients can have nonerosive arthritis and cutaneous nodules too.

- **Positive pathergy test:** Highly specific to Behçet's disease but may be positive in only 50% of Behçet's patients. Pathergy means hyperreactivity of the skin to any intracutaneous injection or needlestick. It involves pricking the skin with a needle to a depth of 5 mm and looking for evidence of papule or pustule development within 48 hours.
- ESR and CRP raised, but not autoantibodies.

Treatment

- **Oral and genital ulceration:** Topical steroid preparations (soluble prednisolone mouthwashes, steroid pastes). Thalidomide (100–300 mg/day for 28 days initially) is very effective for resistant oral and genital ulceration but is teratogenic and neurotoxic.

- Colchicine can be effective for erythema nodosum and joint pain. Apremilast is an alternative to colchicine
- Steroids and immunosuppressants and ciclosporin are indicated for chronic uveitis and rare neurological complications. Anti-TNF agents can be used to control severe uveitis and serious neurological manifestations and gastrointestinal Behçet's disease.

Henoch-Schönlein Purpura/IgA Vasculitis

Q. Write short note on Henoch-Schönlein purpura and anaphylactoid purpura.

- Henoch-Schönlein purpura (also referred to as IgA vasculitis or **anaphylactoid purpura)**, is the most common systemic small-vessel vasculitis in children. It is caused by IgA dominant immune complex deposition following an infectious trigger. It often occurs after upper respiratory tract infections.
- Usually occurs in **children** (>90% of cases) and young adults.

Diagnostic Criteria

Usual presentation: Often present with the **tetrad** of:

1. **Purpura (vasculitis/nonthrombocytopenic/palpable purpura):** Palpable and found over the **buttocks and lower legs (Fig. 8.10).**
2. **Arthralgia or arthritis:** Most patients develop a transient nonmigratory polyarthralgias in the absence of frank arthritis and resolves without permanent damage to joints.
3. **Gastrointestinal involvement:** Seen in about 70% of pediatric patients. It is characterized by recurrent colicky abdominal pain associated with nausea, vomiting, diarrhea, or constipation, and the **passage of blood** and mucus per rectum. In some cases, there may be intussusceptions.
4. **Renal involvement:** Seen in 10–50% of patients. It usually produces mild glomerulonephritis causing proteinuria, microscopic hematuria, with red blood cell casts in the urine. It usually resolves spontaneously without treatment.

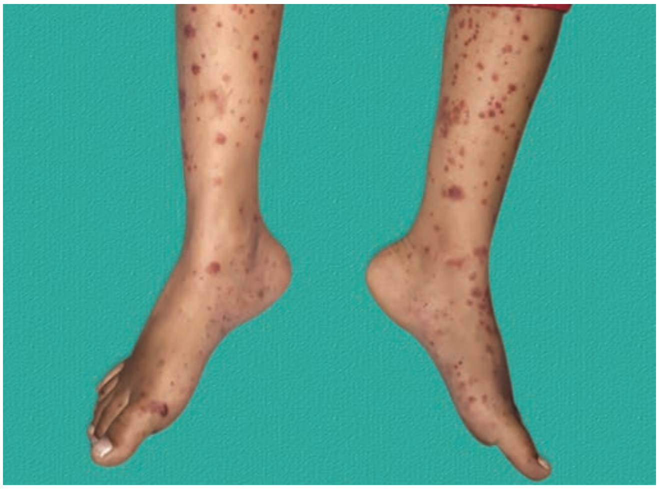


FIG. 8.10: Palpable purpura over lower legs in Henoch-Schönlein purpura.

Other manifestations include scrotal pain keratitis, uveitis, respiratory and neurological involvement.

Prognosis: HSP is self-limited most of the time. The vast majority of cases resolve within 6–8 weeks. Adult cases are sometimes more recalcitrant (not responsive to treatment).

Investigations

- Acute phase reactants are elevated. Serum IgA levels are elevated.
- **Skin biopsy:** Findings are **pathognomonic**. It demonstrates leukocytoclastic vasculitis in capillary venules and direct immunofluorescence of the skin biopsy shows **IgA** immune complexes deposit in the small vessels.

Treatment

- Usually a self-limiting disorder that settles spontaneously without specific treatment.
- Patients respond to bed rest and NSAIDs.
- Corticosteroids and immunosuppressive therapy may be indicated when HSP is severe disease, particularly in the presence of nephritis.

Cogan's Syndrome (CS)

An immune-mediated condition that primarily affects young adults, is associated with ocular inflammation (usually interstitial keratitis) and audiovestibular dysfunction. Maybe associated with large- or medium- to small-sized vessel vasculitis or an aortitis.

Buerger's Disease (Thromboangiitis Obliterans)

- Nonatherosclerotic, segmental, inflammatory disease that affects the small to medium-sized arteries and veins of the extremities.
- Classic patient is a **young male smoker**.
- Identification of the typical pattern of vascular involvement by angiography.
- Major risk factor is tobacco exposure.

- Absence of fibrinoid necrosis (it is a hallmark of most systemic vasculitides).
- Initially, nonspecific pains in the calf, foot, or toes.
- Later, the progression of thrombosis and vasculitis can lead to horrific pain in the digits and limbs and ultimately to gangrene and tissue loss, through either autoamputation or elective amputation.
- The only effective intervention in Buerger disease is **complete smoking cessation**.
- Intermittent pneumatic compressions, calcium channel blockers, phosphodiesterase inhibitors may help in pain relief. Amputate limb when all else fails.
- Other approaches—bosentan, bone marrow mesenchymal stem cells, fibroblast growth factors, granulocyte colony-stimulating factor, and hepatocyte growth factor have been effective.

Takayasu Arteritis

Q. Write short essay/note on Takayasu arteritis.

- Takayasu arteritis, named for the Japanese ophthalmologist who first described the ocular manifestations in 1908.
- It is a **large-vessel vasculitis of unknown** cause that chiefly affects **women during their reproductive years. Other names: Pulseless disease, aortic arch syndrome, and occlusive thromboaortopathy.**
- **Sites:** Most common sites are the **aorta** (65%) and the **left subclavian arteries** (93%).
- **Presentation:**
  A triphasic pattern of progression of disease is classically described:
  - **Phase I**: 'Inflammatory' period characterized by systemic complaints, such as fever, arthralgias, and weight loss.
  - **Phase II**: Vessel inflammation, dominated by vessel pain and tenderness.
  - **Phase III**: Fibrotic stage when bruits and ischemia predominate.
- Patients can present in any phase or combination of phases because TA is a chronic, recurrent disease.
- Vascular manifestations include: **Bruit, claudication, hypertension, lightheadedness** (associated with vertebral or carotid artery disease), **unequal blood pressures in the extremities**, carotidynia, aortic regurgitation, and loss of a pulse. Absence pulses in upper limbs (called **reverse coarctation).**
- **Bruits:** Most frequent over the carotid arteries, but also often develop in the supraclavicular or infraclavicular space (reflecting subclavian disease), along the flexor surface of the upper arm (from axillary artery disease), or in the abdomen (from renal or mesenteric artery vasculitis). Many patients have multiple bruits.
- A **widened pulse pressure** and diastolic murmur along the right sternal border may signal the aortic regurgitation that develops in 20% of patients. Stroke, angina, and congestive heart failure affect a significant minority of patients.
- **Cardiac complications:** Hypertension, congestive heart failure, angina, and aortic regurgitation.
- About 50% of patients develop **constitutional or musculoskeletal symptoms**. Asthenia, weight loss, fever, myalgia, and arthralgia occur commonly.
- Criteria for the diagnosis of Takayasu arteritis **(Box 8.13)**.

Investigations

- Elevated erythrocyte sedimentation rates or C-reactive protein values during phases of active disease.
- Anemia and thrombocytosis
- Vascular abnormalities can be imaged by conventional angiography, MRI, MRA, CT angiography, or ultrasonography. **Conventional angiography is the 'gold standard' for precisely delineating the stenosis, occlusions, and aneurysms.**

Box 8.13: American College of Rheumatology classification criteria for Takayasu arteritis.

- Onset at age <40 years
- Limb claudication
- Decreased brachial artery pulse
- Unequal arm blood pressures (>10 mm Hg)
- Subclavian or aortic bruit
- Angiographic evidence of narrowing or occlusion of the aorta or its primary branches, or large limb arteritis

Note: The presence of three or more of the six criteria is sensitive (91%) and specific (98%) for the diagnosis of Takayasu arteritis.

Treatment

- High-dose glucocorticoids in combination with a glucocorticoid-sparing agent (methotrexate, mycophenolate, leflunomide)
- Vascular intervention—for treatment of stenosed arteries leading to organ ischemia or hypertension and for aneurysmal disease.

Q. Differentiate between giant cell arteritis and Takayasu's arteritis.

Differences between giant cell arteritis and Takayasu's arteritis **(Table 8.23)**.

OSTEOARTHRITIS

Q. Discuss the pathogenesis and clinical features and management of osteoarthritis/degenerative joint diseases.

Osteoarthritis (OA) is the most common form of arthritis. OA refers to a **clinical syndrome of joint pain** accompanied by **varying degrees of functional limitation** and reduced quality of life.

OA is a **noninflammatory**, **slowly progressive joint disease**, mainly **involving the cartilage**. It shows **progressive destruction of articular cartilage** of weight-bearing joints of **genetically susceptible older persons**. It leads to narrowing of joints, subchondral bone thickening, and finally **nonfunctioning, painful joints**.

Joints Affected

- **Weight bearing joints** (knee, hips and cervical and lumbar segments of the spine).
- **Nonweight bearing** distal interphalangeal (DIP) joints, thumb bases (first CMC joints and trapezioscaphoid joints), first MTP joints, lower cervical and lumbar facet joints, knees, and hips.

Etiology

Osteoarthritis (OA) is a **multifactorial disease** having both genetic and environmental components **(Table 8.24)**.

Types of Osteoarthritis (Box 8.14)

Box 8.14: Types of osteoarthritis.

Idiopathic or primary osteoarthritis: It develops as aging process and may affect few (oligoarticular) or many joints.

- **Localized:** Most commonly affects the hands, feet, knee, hip, and spine.
- **Generalized:** Involves three or more joint sites

Secondary osteoarthritis: It appears in younger individuals with predisposing condition.

- Previous injuries/trauma to a joint
- Congenital or developmental deformity of a joint(s)
- Secondary to systemic disease [e.g. diabetes, marked obesity, acromegaly, hypothyroidism, neuropathic (Charcot) arthropathy]
- Calcium pyrophosphate dihydrate deposition disease (CPPD)
- Bone and joint disorders including rheumatoid arthritis, gouty arthritis, septic arthritis, and Paget disease of bone and osteonecrosis

Identifiable Causes of Osteoarthritis

See **Table 8.25**.

Clinical Manifestations

Age of onset: Usually after age 40.

Joints affected in osteoarthritis **(Table 8.26 and Fig. 8.11)**

TABLE 8.23: Comparison of giant cell arteritis and Takayasu's arteritis.

Feature	*Giant cell arteritis*	*Takayasu's arteritis*
Female-male ratio	2:1	8:1
Age range (years)	50	<40
Average age of onset (years)	72	25
Visual loss	10–30%	Rare
Involvement of aorta or its major branches	25%	100%
Pathology	Granulomatous arteritis	Granulomatous arteritis
Pulmonary artery involvement	No	Possible
Renal hypertension	Rare	Common
Claudication	Uncommon	Common
Ethnic groups with highest incidence	Scandinavians	Asians
Corticosteroid responsive	Yes	Yes
Bruits present	Minority	Majority
Surgical intervention	Rarely needed	Commonly needed

TABLE 8.24: Risk factors for incidence and progression of osteoarthritis.

Risk factors	
Age	Normal aging process causes increased progression
Trauma	Collateral ligament, meniscal tears and joint fractures
Occupation	Heavy physical work (e.g. dockers, miners and farmers)
Exercise	High impact sports
Gender	Men under the age of 50 and women over 50
Genetics	Genetic susceptibility to the disease. Genes involved in **prostaglandin** metabolism and **Wnt** (Wingless-related integration site) signaling pathway
Obesity	Strongest modifiable risk factor
Diet	Lower vitamin C and D blood levels
Bone density	Increasing bone density

TABLE 8.25: Identifiable causes of osteoarthritis.

Congenital disorder (hip) ➢ Legg-Calvé-Perthes disease ➢ Acetabular dysplasia ➢ Slipped capital femoral epiphysis	**Metabolic disorders** ➢ Hemochromatosis ➢ Wilson disease ➢ Ochronosis (alkaptonuria)
Inborn error of connective tissue ➢ Ehlers-Danlos syndrome ➢ Marfan syndrome	**History of a septic joint**
Post-traumatic (knee) ➢ Anterior cruciate ligament tear ➢ Meniscus tear with or without prior meniscectomy surgery	**Postinflammatory** Underlying rheumatoid arthritis

TABLE 8.26: Joints affected in osteoarthritis.

Commonly affected joints		***Uncommonly affected joints***
Cervical and lumbar spine	Hip	Shoulder
First carpometacarpal joint	Knee	Wrist
Proximal interphalangeal joint	Subtalar joint	Elbow
Distal interphalangeal joint	First metatarsophalangeal joint	Metacarpophalangeal joint "Missouri metacarpal syndrome"

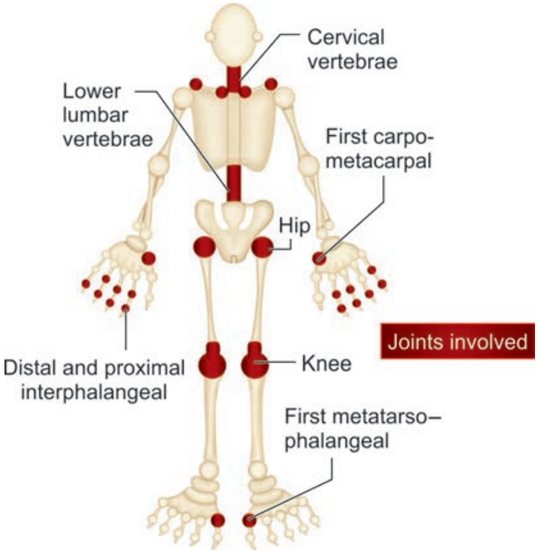

FIG. 8.11: Pattern of joint involvement in osteoarthritis.

Signs, Symptoms and Diagnostic Features of Osteoarthritis (Box 8.15)

Box 8.15: Signs, symptoms and diagnostic features of osteoarthritis.

Symptoms
- Joint pain that increases with activity
- Stiffness: Morning stiffness relatively brief (for <30 minutes) and self-limited
- Gelling

Physical findings
- Crepitus (a grating sensation) on active motion
- Bony enlargement at the joint margin, hard bony enlargements, called **Heberden's nodes** (on DIP) and/or **Bouchard's nodes** (on PIP) **(Fig. 8.12)**
- Decreased range of motion
- Malalignment
- Tenderness to palpation over the joint
- Absence of warmth

Synovial fluid analysis
- Clear fluid
- Noninflammatory synovial fluid (<1000 WBC/mm^3)
- Normal viscosity

Erythrocyte sedimentation rate normal for age

Negative serologic tests for **antinuclear antibody** and **rheumatoid factor**

Radiographic features

Nonuniform joint space narrowing **(Fig. 8.13)**. Subchondral eburnation (bony sclerosis), marginal osteophytes (spur) formation subchondral cysts, "Gull wing" sign in "erosive" OA

Diagrammatic representation of joint changes in osteoarthritis is shown in **Figure 8.14**.

Prevention

Preventing the onset of OA requires lifestyle changes.

- **Primary prevention:** These include:
  - Weight control: Maintaining or reducing weight.
  - Occupational injury prevention: Avoiding repetitive joint use and its injuries.

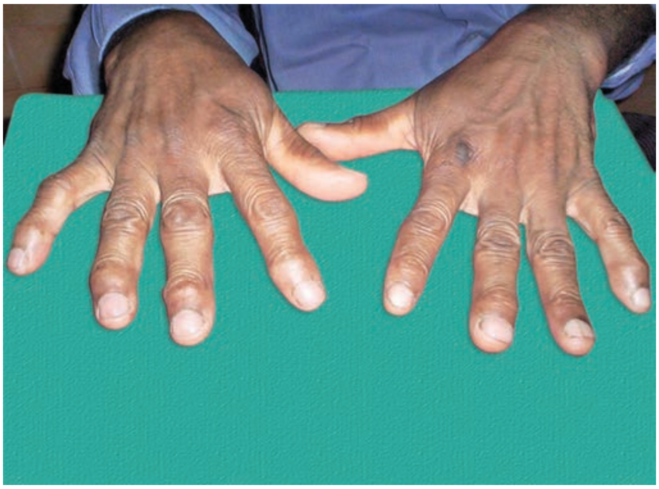

FIG. 8.12: Osteoarthritis showing Heberden's nodes (on DIP) and Bouchard's nodes (on PIP).

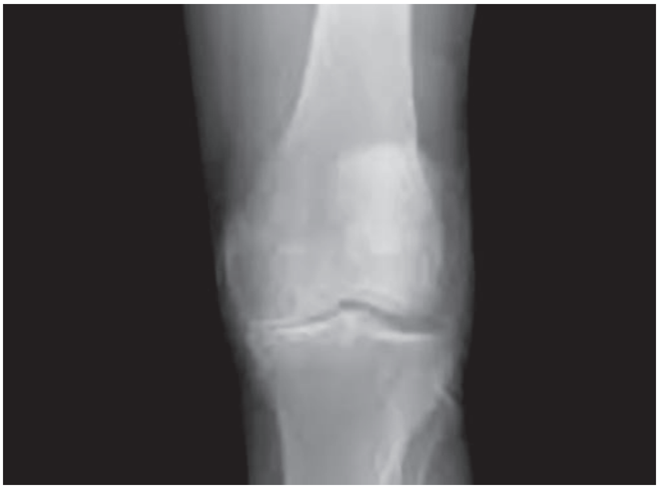

FIG. 8.13: Radiological features of osteoarthritis.

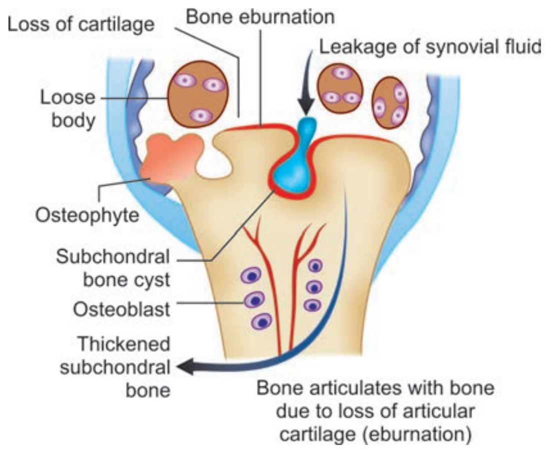
  - Sports injury prevention: Precautions to prevent injury such as warming up and using proper equipment.
- **Secondary prevention:** Early diagnosis so that appropriate early intervention can be utilized. **However, this is difficult in OA since no effective biomarkers are available to determine the progression of the disease.**
- **Tertiary prevention**: Reduce, delay the onset of complications and disability. The strategies include self-management (weight control, physical activity, education); home help programs; cognitive behavioral interventions; rehabilitation services and medical surgical treatments.



Loss of cartilage
Bone eburnation
Leakage of synovial fluid
Loose body
Osteophyte
Subchondral bone cyst
Osteoblast
Thickened subchondral bone
Bone articulates with bone due to loss of articular cartilage (eburnation)

FIG. 8.14: Diagrammatic representation of joint changes in osteoarthritis.

Therapeutic Options in Osteoarthritis (Table 8.27)

TABLE 8.27: Therapeutic options in osteoarthritis.

Nonpharmacological treatment
- Education (patient and spouse or family)
- Social support
- Physiotherapy (physical therapy)
- Occupational therapy
- Weight loss
- Exercise
- Orthotic devices
- Laser
- Pulsed EMF (electromagnetic field therapy)
- Ultrasound
- Transcutaneous electrical nerve stimulation (TENS)
- Acupuncture
- Nutrients
- Herbal remedies
- Vitamins/minerals

Pharmacological treatment
- Paracetamol/acetaminophen
- NSAIDs (non-steroidal anti-inflammatory drugs)
- COX-2 inhibitors (cyclo-oxygenase-2 selective non-steroidal anti-inflammatory drugs)
- Opioid analgesics
- Hormones
- Psychotropic drugs
- SYSADOA [symptomatic slow-acting drugs for OA: avocado/soybean unsaponifiables (ASU), chondroitin, diacerein and glucosamine]
- Topical NSAIDs
- Topical capsaicin

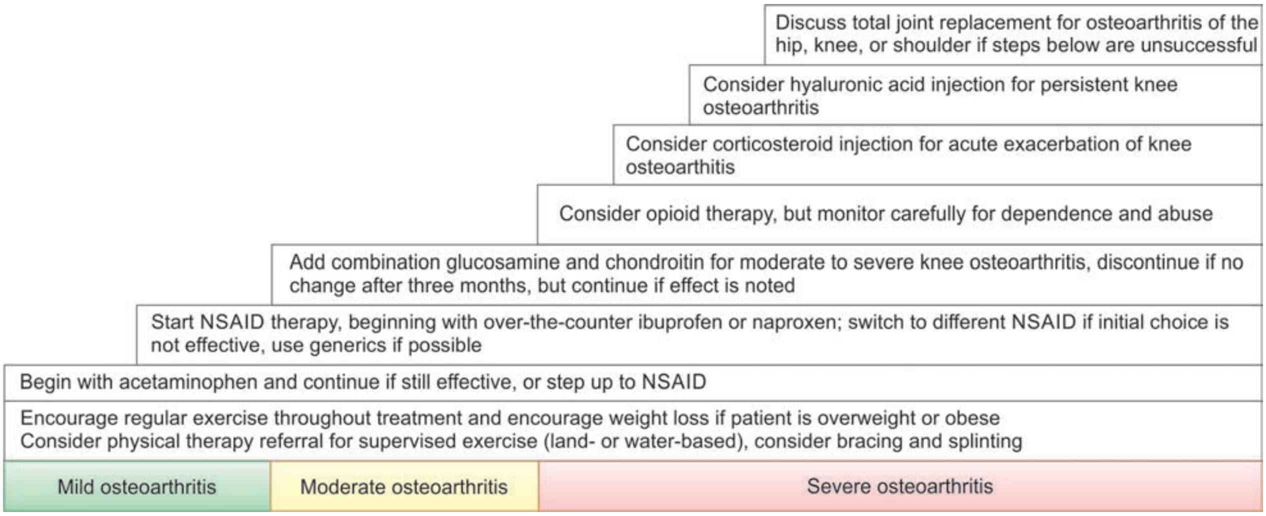
Intra-articular treatment: Corticosteroids, hyaluronans, tidal irrigation

Surgical
- Arthroscopy
- Osteotomy
- Unicompartmental knee replacement (UKR)
- Total knee replacement (TKK)
- Total hip replacement (THR)

Drugs in the pipeline

Inhibition of breakdown of cartilage by collagenolytic enzymes or matrix metalloproteinases (MMPs)—
- *Doxycycline*
- *Therapy that stimulates repair activity by chondrocytes*
- *Bisphosphonates*
- *Growth factors*
- *Cathepsin K inhibition*

Q. Write short essay/note on management of osteoarthritis.



Discuss total joint replacement for osteoarthritis of the hip, knee, or shoulder if steps below are unsuccessful

Consider hyaluronic acid injection for persistent knee osteoarthritis

Consider corticosteroid injection for acute exacerbation of knee osteoarthritis

Consider opioid therapy, but monitor carefully for dependence and abuse

Add combination glucosamine and chondroitin for moderate to severe knee osteoarthritis, discontinue if no change after three months, but continue if effect is noted

Start NSAID therapy, beginning with over-the-counter ibuprofen or naproxen; switch to different NSAID if initial choice is not effective, use generics if possible

Begin with acetaminophen and continue if still effective, or step up to NSAID

Encourage regular exercise throughout treatment and encourage weight loss if patient is overweight or obese
Consider physical therapy referral for supervised exercise (land- or water-based), consider bracing and splinting

SYSTEMIC SCLEROSIS (SCLERODERMA)

Q. Describe the clinical manifestations, diagnosis and management of systemic sclerosis.

Systemic sclerosis (SSc) is a **chronic multisystem disease** of connective tissue **affecting the skin, musculoskeletal system, internal organs** (e.g. gastrointestinal tract, lungs, heart and kidneys) and vasculature. Scleroderma literally means 'hard skin' and the hallmark of SSc is thickening and **hardening of the skin** (scleroderma) due to skin fibrosis.

Classification

Systemic sclerosis is classified and subdivided into two principal subsets defined largely by the anatomic skin distribution and associated with distinct clinical and laboratory manifestations.

Diffuse cutaneous systemic sclerosis (DCSS: 30% of cases): It is associated with progressive skin thickening, starting in the fingers and ascending from distal to proximal extremities, the face, and the trunk. These patients have a risk of early pulmonary fibrosis and involvement of kidney and other systems.

Q. Write short note on CREST syndrome and its clinical features.

- **Limited cutaneous systemic sclerosis (LCSS:** 70% of cases). Usually, these patients have long-standing Raynaud's phenomenon before other manifestations. Skin involvement progresses slowly and remains limited to the fingers (sclerodactyly), distal extremities, and face, without involvement of trunk. Few of these patients have prominent **C**alcinosis cutis, **R**aynaud's phenomenon, **E**sophageal dysmotility, **S**clerodactyly (scleroderma of the fingers), and **T**elangiectasia, which is termed **CREST syndrome**. CREST syndrome generally shows slow progression.
- Other two types are:
  1. **Systemic sclerosis sine scleroderma:** A small group of patients have no detectable skin involvement but have clinical features such as Raynauds, digital ulcers, and autoantibodies for SSc.
  2. **Systemic sclerosis with overlap syndrome:** SSc with overlap or features of another systemic rheumatic disease such as systemic lupus erythematosus (SLE), rheumatoid arthritis, polymyositis, or Sjögren's syndrome.

Age and gender: Peak incidence is between 30 and 50 years of age with female to male ratio of 3:1.

Etiology: The cause is poorly understood. There is associations with alleles at the HLA locus have been found. There is immunological dysfunction of T lymphocytes, especially Th1 and Th17 subtypes.

Clinical Features

Q. Write short note on symptoms and signs of systemic sclerosis.

Skin Manifestations

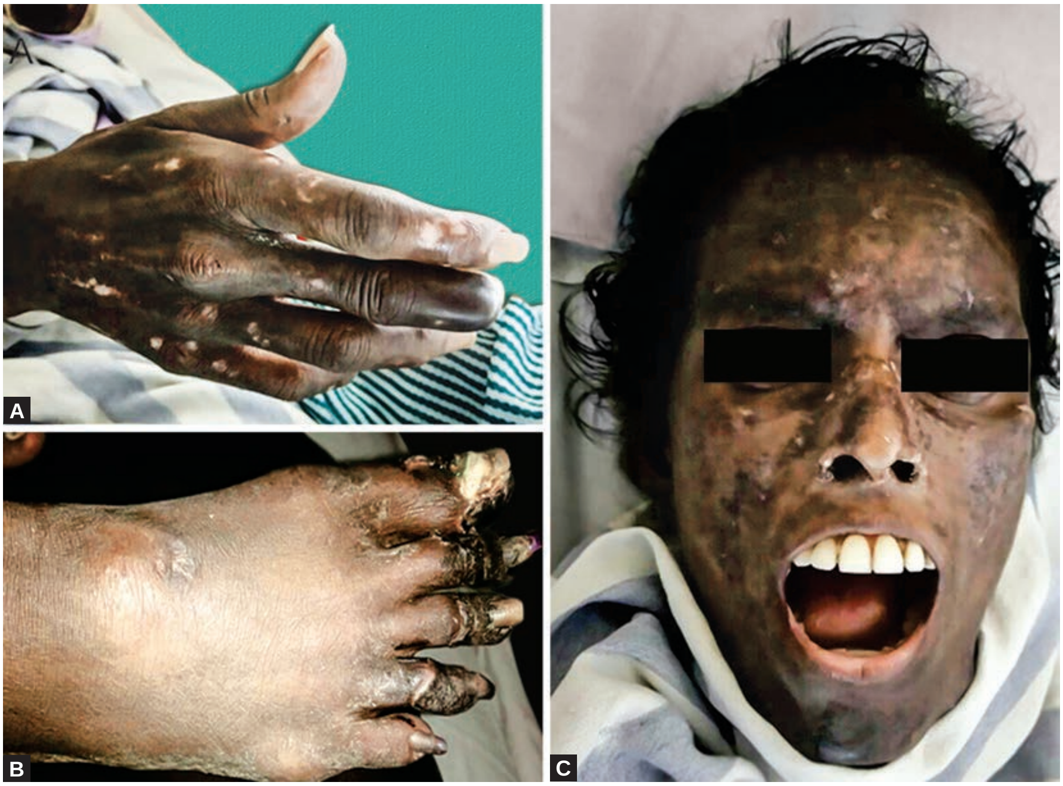
- **Limited disease or CREST syndrome:** Skin involvement restricted to sites distal to the elbow or knee (apart from the face).
- **Diffuse disease:** Skin involvement proximal to the knee and elbow and on the trunk.

Changes in skin (Figs. 8.15A to C)

- Symmetrical and bilateral skin thickening is the hallmark of SSc.
- **Early stage:** Shows non-pitting edema of fingers and flexor tendon sheaths.
- **Later stages:** Skin becomes shiny, firm, thickened, and distal skin creases disappear. After many years, the skin may become thin, atrophic and tightly bound to underlying subcutaneous tissue.
- **Hyperpigmentation:** Skin generally becomes hyperpigmented. In dark-skinned individuals, vitiligo-like areas of hypopigmentation may occur. Because pigment loss spares the perifollicular areas, the skin may develop a **'salt-and-pepper'** appearance most prominently on the upper back and chest.
- **Changes in facial skin:** Produces a beak-like nose, 'mask- like' face, and decreased oral aperture (microstomia) (**mauskopf facies).**
- The **modified Rodnan skin score (mRSS)** is used clinically and in clinical trials to quantify skin involvement.
- **Other manifestations:** These include flexion contractures, ulcers over fingertips and bony prominences (due to breakdown of atrophic skin), telangiectasia, calcinosis cutis and dry coarse skin.

Musculoskeletal Manifestations

- Range from mild arthralgias to frank nonerosive arthritis with synovitis resembling rheumatoid arthritis.
- Generalized arthralgia, morning stiffness and flexor tenosynovitis are common.



FIGS. 8.15A TO C: Systemic sclerosis. (A and B) Show shiny, thickened skin of hands and feet; (C) Shows mask like face with decreased oral aperture.

- Muscle weakness and wasting due to disuse atrophy, myopathy and myositis.
- Restricted hand/limb function associated with contractures of the joints is due to sclerosis of skin rather than joint disease.
- Bone resorption is most common in the terminal phalanges, where it causes loss of the distal tufts (acro-osteolysis) (pseudoclubbing).

Vascular Manifestations

- Involvement of the vasculature is **universal feature** of SSc.
- **Raynaud's phenomenon** is an **episodic reversible vasoconstriction of the vessels of the digits** (fingers and toes) that can result in ischemia of the digits. It occurs in all patients with SSc and can precede other features by many years. This is the first manifestation of the disease in almost every patient.
  - **Triggering factors:** Factors which trigger attack include exposure to cold, a decrease in temperature, emotional stress, and vibration. Typical attacks start with pallor (vasoconstriction), followed by cyanosis (ischemia) of variable duration and erythema (reperfusion) develops spontaneously or with rewarming of the digit. There does not need to be a three-color change to diagnose Raynaud's phenomenon; episodic pallor or cyanosis that reverses to erythema or normal skin color may be all that is seen. Patients may describe symptoms of numbness, tingling, or pain on recovery.
- A **diffuse vasculopathy of peripheral arteries** (in the extremities) may cause narrowing or occlusion of the vessel lumen leading to tissue ischemia. This may produce skin ulceration over pressure areas, localized areas of infarction and pulp atrophy at the fingertips.
- Vascular disease is fundamental to organ damage and subsequent malfunction of the heart (cardiomyopathy), lung (pulmonary hypertension), kidney [scleroderma renal crisis (SRC)], and other organs in SSc.

Gastrointestinal Manifestations

Gastrointestinal disease in scleroderma usually involves both the upper and lower gastrointestinal tract but clinical expression is highly variable.

- **Esophageal involvement:** It can manifest as reflux with erosive esophagitis, dysphagia and odynophagia, strictures, and dilatation and atony of lower esophagus.

- **Stomach involvement:** It results in dilatation, atony and delayed gastric emptying. Recurrent occult upper gastrointestinal bleeding may occur due to gastric antral vascular ectasia (GAVE) (**'watermelon' stomach**) **(Fig. 8.16)**.
- **Small and large bowel involvement:** It results in intermittent abdominal distension, abdominal pain, constipation, intestinal obstruction, malabsorption (due to bacterial overgrowth) and steatorrhea. **Pseudo-obstruction** is a known complication.

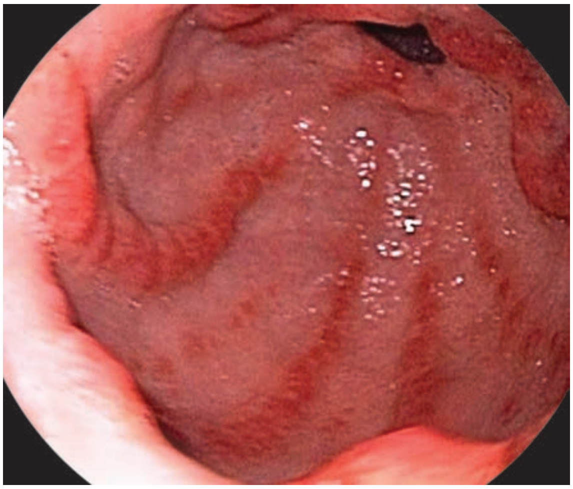


FIG. 8.16: Gastric antral vascular ectasia (watermelon stomach) in scleroderma.

Pulmonary Manifestations

It is a major cause of morbidity and mortality. Main forms of lung disease—inflammatory alveolitis leading to interstitial fibrosis and pulmonary arterial hypertension.

Other Manifestations

- **Renal involvement:** Occurs in only a minority of patients and can be acute or chronic. Acute hypertensive renal crisis (scleroderma renal crisis-SRC) characterized by sudden onset of malignant hypertension and renal failure was used to be the most common cause of death. At present, this is not the case because ACE inhibitors with dialysis and renal transplantation have improved the outlook.
- **Cardiac involvement:** Myocardial fibrosis may cause arrhythmias, conduction defects and cardiomyopathy. Occasionally, pericarditis with or without effusion may develop.
- **Localized scleroderma:** Localized form without systemic involvement **(morphea)**.

Diagnosis (Box 8.16)

Box 8.16: Criteria for diagnosis of scleroderma.

- Thickened (sclerodermatous) skin changes proximal to the metacarpophalangeal joints

OR

- At least two of the following:
  - Sclerodactyly
  - Digital pitting (residual loss of tissue on the finger pads due to ischemia)
  - Bibasilar pulmonary fibrosis

Investigations

- **ESR:** Elevated.
- **IgG levels:** Raised.
- **Anemia:** It may be due to: (1) **chronic disease, (2) iron deficiency** due to gastrointestinal bleed, (3) **folate and B_{12} deficiency** due to blind loop syndrome and (4) m**icroangiopathic hemolytic anemia** due to renal involvement.
- **Urea and creatinine:** Raised in acute kidney injury.
- **Urine** microscopy and if there is proteinuria, measurement of urine albumin/creatinine ratio.
- **Autoantibodies associated with scleroderma (Table 8.28)**
- **Rheumatoid factor:** Positive in 30%.
- **Nail-fold capillary changes:** Visualization of capillaries of the skin at the nail-fold by diascopy gives insight into a patient's microvasculature status. Nail-fold capillary dropout and dilated capillary loops are seen in nearly every patient with scleroderma but are not specific for scleroderma.
- **Imaging**
  - **Chest X-ray:** For changes in cardiac size and evidence of lung disease.
  - **X-ray of hands:** For deposits of calcium around fingers. In severe cases, erosion and absorption of the distal phalanges (acro-osteolysis).
  - **Barium swallow:** To demonstrate impaired esophageal motility. Scintigraphy, manometry, impedance, and upper GI endoscopy are also useful.
  - **High-resolution CT:** To demonstrate interstitial lung disease.
- **Other investigations:** Echocardiography for cardiac involvement and pulmonary hypertension.

ACR/EULAR criteria for classification of systemic sclerosis provided in **Table 8.29**.

TABLE 8.28: Autoantibodies associated with scleroderma.

Autoantibody	*Prevalence*
Antinuclear antibody	>95%
Anti-Scl-70 (anti-topoisomerase I)	20–40%
Anti-centromere	20–40%
Anti-RNA polymerases	4–20%
Anti-B23	10%
Anti-Pm-Scl	2–10%
Anti-U3-RNP (anti-fibrillarin)	8%
Anti-U1-RNP	5%
Anti-Th/To	1–5%

TABLE 8.29: 2013 ACR/EULAR criteria for the classification of systemic sclerosis (scleroderma).*

Item	*Sub-item(s)*	*Weight/score*†
Skin thickening of the fingers of both hands extending proximal to the metacarpophalangeal joints (*sufficient criterion*)	–	9
Skin thickening of the fingers (*only count the higher score*)	Puffy fingers Sclerodactyly of the fingers (distal to the metacarpophalangeal joints but proximal to the proximal interphalangeal joints)	2 4
Fingertip lesions (*only count the higher score*)	Digital tip ulcers Fingertip pitting scars	2 3
Telangiectasia	–	2
Abnormal nail-fold capillaries	–	2
Pulmonary arterial hypertension and/or interstitial lung disease (*maximum score is 2*)	Pulmonary arterial hypertension Interstitial lung disease	2 2
Raynaud's phenomenon	–	3
SSc-related autoantibodies (anticentromere, anti–topoisomerase I [anti–Scl-70], anti–RNA polymerase III) (*maximum score is 3*)	Anticentromere 3 Anti–topoisomerase I Anti–RNA polymerase III	3

* The criteria are not applicable to patients with skin thickening sparing the fingers or to patients who have a scleroderma-like disorder that better explains their manifestations (e.g., nephrogenic sclerosing fibrosis, generalized morphea, eosinophilic fasciitis, scleredema diabeticorum, scleromyxedema, erythromelalgia, porphyria, lichen sclerosis, graft-versus-host disease, diabetic cheiroarthropathy).

† The total score is determined by adding the maximum weight (score) in each category.

Patients with a total score of ≥9 are classified as having definite scleroderma.

Treatment

There is no cure and no treatment can halt or reverse the fibrotic changes produced in systemic sclerosis. Treatment should be organ-based to ameliorate the effects of the disease on target organs.

- **General measures:**
  - Education, counseling and family support.
  - Regular exercises and skin lubricants.
  - Monitoring of blood counts, renal functions and analysis of urine on regular basis.
- **Control of Raynaud's syndrome and digital ulcers**
  - Raynaud's phenomenon: **Avoid triggering factors.** Use hand warmers, and oral vasodilators (**calcium-channel blockers**, ACE inhibitors, angiotensin receptor blockers). Parenteral vasodilators (prostacyclin analogues and calcitonin gene-related peptide) may be beneficial in severe digital ischemia.
  - **Digital ulcers:** Endothelin 1 antagonist bosentan promotes healing of digital ulcers. If ulcers become infected, antibiotics may be required.
  - **Surgical management:** Lumbar **sympathectomy**, radical microarteriolysis (digital sympathectomy), and thoracic sympathectomy may be beneficial.
- **Hypertension:** Treated aggressively with **ACE inhibitors**, even if renal impairment is present.
- **Esophageal reflux:** Treated with **proton pump inhibitors** and anti-reflux agents, but prokinetic drugs are rarely useful.
- **Intestinal involvement:** Symptomatic malabsorption requires nutritional supplements. Antibiotics may be necessary for small intestinal bacterial overgrowth syndromes, and metoclopramide or domperidone may be useful for symptoms of pseudo-obstruction.
- **Joint involvement:** Treated with analgesics and/or NSAID. If synovitis is present, immunosuppressants such as methotrexate can be used.
- **Pulmonary hypertension:** Treated with oral vasodilators, oxygen and warfarin. Advanced cases require prostacyclin therapy (inhaled, subcutaneous or intravenous) or the oral endothelin-receptor antagonists (bosentan and sitaxsentan). Low-dose oral corticosteroids and cytotoxic drugs (e.g. cyclophosphamide or azathioprine) are indicated when myositis or pulmonary fibrosis is co-exist.
- **D-Penicillamine:** May reduce skin thickening and also systemic involvement.
- Progressive and diffuse skin involvement without visceral involvement, methotrexate (MTX) or mycophenolate mofetil (MMF).

Prognosis

Prognosis is highly dependent on the extent of major organ disease. Can be predicted to some extent by the degree of skin involvement:

- Limited scleroderma has a normal life expectancy, about 90% 5-year survival rate.
- Diffuse skin disease have only about a 70–80% 5-year survival rate.

SJÖGREN'S SYNDROME

Q. Discuss the clinical manifestations, diagnosis and management of Sjögren's syndrome (SS).

It **mainly affects the exocrine** (salivary and lachrymal) **glands** and is characterized by the immune-mediated destruction of exocrine glands with secondary development of **keratoconjunctivitis sicca** (dry eyes) and **xerostomia** (dryness of the mouth).

Classification

- **Primary:** Sjögren's syndrome (sicca syndrome): It occurs in the absence of any underlying connective tissue disorder.
- **Secondary:** It occurs in association with other autoimmune disorders. These include rheumatoid arthritis, systemic lupus erythematosus, systemic sclerosis (scleroderma), mixed connective tissue disease, primary biliary cirrhosis, vasculitis and chronic active hepatitis.

Age and gender: Usual age of onset is **40 to 50 years**, with **female** to male ratio of 9:1. Mechanisms of tissue destruction: Lymphocytic infiltration and immune-complex deposition.

Clinical Features (Table 8.30)

TABLE 8.30: Major clinical manifestations of Sjögren syndrome.

Organ	***Manifestations***
Mouth	Oral dryness (xerostomia), soreness, caries, periodontal disease, oral candidiasis, parotid swelling
Eyes (keratoconjunctivitis sicca)	Ocular dryness (xerophthalmia), corneal ulcers, conjunctivitis and blepharitis (lack of lubricating tears)
Nose and throat	Nasal dryness, chronic cough
Extraglandular manifestations	
Skin	Cutaneous dryness, palpable purpura, urticarial lesions, Raynaud phenomenon
Joints	Arthralgias, non-erosive symmetric arthritis
Lungs	Obstructive chronic lung disease, interstitial pneumopathy
Cardiovascular	Raynaud phenomenon, pericarditis, autonomic disturbances
Liver	Associated hepatitis C virus infection, primary biliary cirrhosis, type 1 autoimmune hepatitis
Kidneys	Renal tubular acidosis type I (distal), glomerulonephritis
Peripheral nerve	Mixed polyneuropathy, pure sensitive neuropathy, mononeuritis multiplex
Central nervous system	White matter lesions, cranial nerve involvement (V, VIII, and VII), myelopathy
Ears	Sensorineural hearing loss
Thyroid	Autoimmune (Hashimoto's) thyroiditis
General symptoms	Low-grade fever, generalized pain, myalgias, fatigue, weakness, fibromyalgia, polyadenopathies, depression, anxiety, increased risk of non-Hodgkin's lymphoma

Q. Write short note on keratoconjunctivitis sicca.

Laboratory Investigations

- **Schirmer tear test:** This is the most commonly used test for the diagnosis of SS. It measures wetting of standardized tear test strip by tear flow over 5 minutes. A standard tear test (absorbent) paper strips is placed between the eyeball and inside of the lower eyelid. Normal result is more than 10 mm of wetting in 5 minutes and if wetting is <10 mm in 5 minutes it indicates defective tear production.
- **Rose Bengal staining**. Staining of the eyes with rose Bengal may show punctate or filamentary keratitis over the area not covered by the open eyelid.
- **Biopsy:** If the diagnosis remains in doubt, it can be confirmed by biopsies of the salivary gland or of the lip (labial minor salivary gland). They show a focal infiltration by lymphocytes and plasma cells. Minor salivary gland biopsy remains a highly specific test for the diagnosis of SS.
- **Tests for salivary gland involvement:** Other diagnostic tests include sialometry (to measure salivary flow), sialography, and scintigraphy. Newer imaging techniques such as ultrasound, MRI or MR sialography of the major salivary glands are also useful.
- **Common laboratory abnormalities**
  - Most patients have an elevated ESR, raised immunoglobulin levels (hypergammaglobulinemia), and circulating immune complexes.

- Autoantibodies
  - Rheumatoid factor: Usually positive (75–90%).
  - Antinuclear antibodies: Positive in 80% of cases.
  - Anti-mitochondrial antibodies: Positive in 10%.
  - Anti-Ro (SSA) antibodies: Positive in 60–90% (in 10% of cases of RA and secondary Sjögren's syndrome). This antibody can cross the placenta and cause congenital heart block.
  - Anti-La (SSB) antibodies: Present in 40%.
- Others: Leukopenia, thrombocytosis.

Diagnosis: The 2016 EULAR criteria for SS. A patient is considered to have primary SS if they have at least one symptom of ocular or oral dryness and have a score of ≥4 points out of 9 from the following items:

- Labial salivary gland biopsy with lymphocytic sialadenitis and a FS (focus score) ≥1 foci/4 mm^2 (3 points).
- Anti-SSA/Ro positive (3 points).
- OSS (Ocular Staining Score) ≥5 in at least one eye (1 point).
- Schirmer's test ≤5 mm/5 minutes in at least one eye (1 point).
- Unstimulated whole salivary flow rate ≤0.1 mL/minute (1 point).

Treatment

- Management is symptomatic.
- **Ocular symptoms:** Symptomatic treatment is with artificial tears. Lachrymal substitutes (e.g. hypromellose) during the day and more viscous ophthalmologic lubricating ointment at night. Cyclosporine emulsion may be useful in ocular dryness.
- **Oral symptoms:** Best replacement for xerostomia is water, lubricating agents and saliva-replacement solutions. Stimulation of saliva flow by sugar-free chewing gum or lozenges may be helpful. Vaginal dryness is treated with lubricants such as K-Y jelly.
- **Muscarinic agonists** (pilocarpine and cevimeline) have been recently used for the treatment of sicca symptoms in SS. They stimulate the M1 and M3 receptors present on salivary glands and tear glands leading to increased secretory function.
- Hydroxychloroquine is helpful for fatigue and arthralgia.
- Glucocorticoids and immunosuppressive agents are reserved for potentially severe disease. Corticosteroids are used to treat persistent salivary gland swelling or neuropathy. Other agents that can be used are hydroxychloroquine, methotrexate, leflunomide, azathioprine, sulfasalazine, mycophenolic acid, and cyclosporine.
- Biological agents, including infliximab, interferon-α and anti-CD20 antibodies (rituximab) are tried.

Overlap Syndromes and Mixed Connective Tissue Disease (MCTD)

Q. Define mixed connective tissue disease/overlap syndromes.

Overlap syndromes are diseases in which clinical or laboratory signs and symptoms of another defined connective tissue disease occur, such as systemic lupus erythematosus, scleroderma, rheumatoid arthritis, Sjogren's syndrome, Churg–Strauss arteritis, thrombotic thrombocytopenic purpura, antiphospholipid antibody syndrome and autoimmune thyroid disease. **Mixed connective-tissue disease** (MCTD) is a disorder with overlapping clinical features of systemic lupus erythematosus, scleroderma, and myositis, with the presence of a distinctive antibody against **U1-ribonucleoprotein (RNP)**. U1 RNP consists of ribonucleic acid (RNA) plus three proteins (A', C, and a 68-70 kD protein).

CRYSTAL ARTHROPATHIES

Gout

Q. Describe the etiology, clinical manifestations, diagnosis and management of gout.

Q. Discuss the causes, clinical manifestations, investigations and management of hyperuricemia.

Gout is a **heterogeneous group of inflammatory diseases** characterized by **hyperuricemia** (plasma urate level above 6.8 mg/dL) and monosodium **urate crystal deposition in** and around synovial **joints and kidneys**.

Etiology of Gout and Hyperuricemia (Box 8.17)

Q. Write short note on causes of hyperuricemia.

Uric acid is the end product of purine metabolism, which is eliminated only in the urine. Humans do not have uricase, an enzyme which degrades uric acid. Usually, there is a balance between uric acid production and tissue deposition of urates.

Clinical Features

The natural history of gout has four stages:

1. **Asymptomatic hyperuricemia:** It is a state in which serum urate exceeds the level of solubility but symptoms of crystalline deposition have not occurred. Appears at puberty in males and after menopause in females.
2. **Acute gouty arthritis:**
    - Acute gouty arthritis usually follows decades of asymptomatic hyperuricemia. Usually the **first attack** occurs in a **middle aged male**.
    - **Presentation:** It appears as **sudden excruciating** (agonizing) **joint pain, swelling, intense redness** and tenderness of the **first metatarsophalangeal (MTP) joint (termed *podagra*) (Fig. 8.17).** Other joints that can be involved are tarsal joints, ankles, knees and wrists. Gout can also cause bursitis and tenosynovitis. 20% patients can present with a polyarticular pattern is the initial manifestation.
    - **Systemic symptoms:** The acute attack may be accompanied by fever, chills, and malaise, leukocytosis and raised ESR.
    - **Factors which precipitate acute attack** are those that cause fluctuations (rapidly raising or lowering) in serum urate levels. These include overindulgence in certain high-purine foods, alcohol ingestion, starvation, dehydration, certain drugs (e.g. diuretic, salicylates, urate-lowering drugs allopurinol and radiographic contrast agents), trauma and surgery.
    - **Termination of attack:** Even if not treated, acute attacks of gout are usually self-limited, subside spontaneously and first several acute attacks last for 5 to 8 days. Recovery is usually associated with desquamation of the overlying skin. There is no damage to any organ system during the acute attack.
3. **Intercritical gout:** With resolution of the attack, patients enter an interval termed the 'intercritical period'. It is the asymptomatic period between the first acute attack and subsequent attacks. During this period, the previously affected joints are free of symptoms. Despite this, monosodium urate crystal deposition continues.

Box 8.17: Classification of hyperuricemia.

Urate overproduction
- ***Primary hyperuricemia***
    - Idiopathic
    - Complete or partial deficiency of HGPRT
    - Superactivity of PRPP synthetase
- ***Secondary hyperuricemia***
    - Excessive purine consumption
    - Myeloproliferative or lymphoproliferative disorders
    - Hemolytic diseases
    - Psoriasis
    - Glycogen storage diseases: types 1, 3, 5, and 7

Uric acid under excretion
- ***Primary hyperuricemia***
    - Idiopathic
- ***Secondary hyperuricemia***
    - Decreased renal function
    - Metabolic acidosis (ketoacidosis or lactic acidosis)
    - Dehydration
    - Diuretics
    - Hypertension
    - Hyperparathyroidism
    - Drugs including cyclosporine, pyrazinamide, ethambutol and low-dose salicylates
    - Lead nephropathy

Overproduction and under excretion
- Alcohol use
- Glucose-6-phosphatase deficiency
- Fructose-1-phosphate-aldolase deficiency

(HGPRT: Hypoxanthine-guanine phosphoribosyltransferase; PRPP: 5-Phosphoribosyl-1-pyrophosphate)

Q. Write short essay/note on chronic tophaceous gout.

4. **Chronic tophaceous gout** (tophi and chronic gouty arthritis)
    - Eventually the untreated patient progresses to chronic polyarticular gout (advanced gout). This stage usually develops after several years (10 or more years) of acute gouty arthritis, which may lead to severe crippling disease.
    - The intensity of pain in chronic is not severe compared to that of acute attacks.
    - **Most characteristic lesion** of advanced gout is **subcutaneous tophus**. It results from deposition of crystals in cartilage, synovial membranes, tendons and soft tissues. It can occur anywhere in the body but is most common in the fingers, wrists, ears (helix and antihelix), knees, and olecranon bursa.

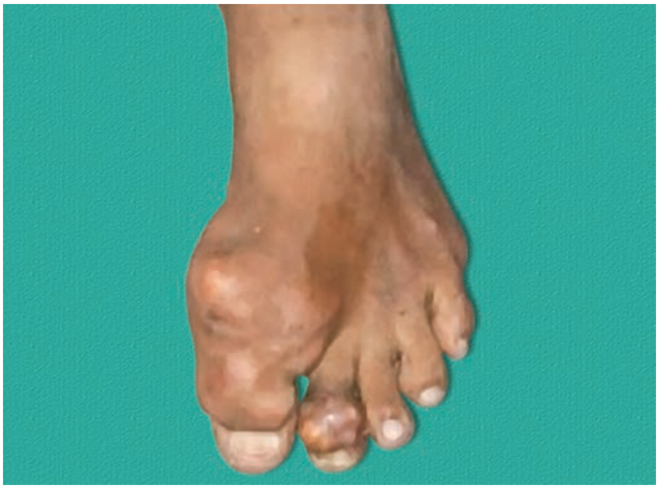

FIG. 8.17: Acute gouty arthritis involving the first metatarsophalangeal (MTP) joint (termed podagra).

Nephropathy

Occurs in 90% of patients with gouty arthritis. Two types of parenchymal renal damage can occur.

1. **Urate nephropathy:** It is characterized by deposition of urate crystals in the interstitial tissue. It may lead to albuminuria, isosthenuria or renal failure.
2. **Obstructive uropathy (nephrolithiasis):** Chronic hyperuricemia may be complicated by formation of uric acid renal stone with blockage of urine flow. The factors favoring stone formation are hyperuricosuria, overproduction of purine, increased ingestion of purine, uricosuric drugs and acidic urine.

Other features: Hypertension is a risk factor for development of gout and gout may be associated with increased incidence of hypertension and cardiovascular disorders.

Investigations

- **Joint fluid microscopy:** Most specific and diagnostic test but is technically difficult. Synovial fluid examined by compensated polarized microscopy shows **urate crystals**. These crystals are bright yellow in color and appear as slender, **needle-shaped, negatively birefringent structures.**
    - **Acute gout:** Synovial fluid is turbid due to the greatly elevated cell count (>90% neutrophils).
    - **Chronic gout:** More variable but occasionally it appears white due to the high crystal load. Crystals may be seen between attacks.
- **Serum uric acid:** Raised hyperuricemia (>7.0 mg/dL in males and >6.0 mg/dL in females) does not confirm the diagnosis. However, levels may be normal (in 50% cases) during an acute attack.
- **Serum urea, creatinine:** Monitoring is needed to detect any signs of renal impairment.
- Raised ESR and CRP and neutrophilia are observed during acute gout, and they return to normal as the attack subsides.
- **Plain radiographs:** Usually normal in acute gout. In chronic or tophaceous gout, well-demarcated rounded or oval punched out erosions with hypertrophic calcified 'overhanging edge' **(Martel sign)** are characteristically observed. RA causes marginal erosions within the limits of the joint capsule.
- **Dual-energy computed tomography (DECT):** Identifies urate deposits in articular and periarticular locations and can distinguish urate from calcium deposition.

Q. Write short note on management of acute attack of gout.

Management

Treatment of acute attack

- **NSAIDs:** They rapidly relieve pain and swelling during the acute attack and are the agents of choice. Commonly used drugs include indomethacin (75 mg immediately, then 50 mg 6–8 hours), naproxen (750 mg immediately, then 500 mg every 8–12 hours), *diclofenac* (75–100 mg immediately, then 50 mg every 6–8 hours) and fenoprofen. NSAIDs may cause renal impairment.
- Local icepacks can produce symptomatic relief.
- **Oral colchicine:** It is the second drug of choice which acts by inhibiting microtubule assembly in neutrophils. It is very effective at a dose of 1.2 mg immediately, then 0.6 mg every 6–12 hours. Side effects include diarrhea or colicky abdominal pain.
- **Corticosteroids:** If patient cannot tolerate NSAIDs or colchicine, oral prednisolone (20–30 mg/day) or intramuscular or intra-articular depot methylprednisolone may be tried.
- **ACTH gel:** A single injection of intramuscular ACTH gel (25 to 80 IU) is useful for terminating an acute attack of gout.
- **Interleukin 1 inhibitors:** Anakinra, canakinumab have been tried.

Prophylaxis

Indicated in patients with recurrent flares, tophi with joint damage and patients with renal insufficiency.

Dietary advice

- Avoid alcohol intake, especially beer, which is high in purines and fructose. Carbonated soft drinks are also rich in fructose.
- Avoid meat and shellfish.
- Controlled weight reduction if patient is obese.
- Avoid use of thiazides or loop diuretics.

Drugs for Prophylaxis

Urate-lowering therapy

It is indicated **(Box 8.18)** in patients who develop more than one acute attack within one year and those with complications. Xanthine oxidase inhibitors are used in urate overproducers while uricosuric agents are used in urate underexcretors.

- **Allopurinol** is the drug of first choice. It is an xanthine oxidase inhibitor that blocks the conversion of xanthine into uric acid. Thus, it reduces uric acid production and serum uric acid levels rapidly.
  - **Indication:** Should be used when the attacks are frequent and severe (despite dietary changes), associated with renal impairment or tophi, or when NSAIDs or colchicine are difficult to tolerate.
  - **Dosage:** 300–900 mg daily.
  - **Common side effects:** These include gastrointestinal intolerance and skin rashes. Allopurinol hypersensitivity syndrome is the most severe reaction characterized by fever, skin rash, eosinophilia, hepatitis, progressive renal insufficiency, and death.

Box 8.18: Indications for urate-lowering drugs.

Hyperuricemia associated with increased uric acid production
- Urinary uric acid excretion of 1000 mg or more in 24 hours
- Very high levels of serum uric acid
- Hyperuricemia associated with HGPRT deficiency or PRPP synthetase overactivity
- Uric acid nephropathy
- Nephrolithiasis
- Prophylaxis before cytolytic therapy
- Evidence of bone or joint damage

(HGPRT: Hypoxanthine guanine phosphoribosyl-transferase; PRPP: 5′-Phosphoribosyl-1-pyrophosphate)

- **Febuxostat** is a non-purine selective inhibitor of xanthine oxidase, is a new urate lowering drug that is possibly well-tolerated, safer in renal impairment and superior to allopurinol. Dose is 40–120 mg/day.
- **Uricosuric agents** like **probenecid, benzbromarone, lesinurad,** and **sulfinpyrazone** are indicated in selected cases (when uric acid excretion in the urine is below 600 mg/day). Uricosuric drugs are risky if urinary urate excretion is already >800 mg/24 hours. These are contraindicated in those with urate calculi. Uricosurics are ineffective in renal impairment (creatinine clearance <50 mL/minute).
- Uricase, analogs as **pegloticase and rasburicase** are used to promote depletion of body urate pools.

Q. Write short note on Lesch–Nyhan syndrome.

- Lesch–Nyhan syndrome is an X-linked recessive disorder characterized by three major clinical elements—overproduction of uric acid, neurological disability and behavioral problems.
- Hyperuricemia may lead to nephrolithiasis, renal failure, gouty arthritis and tophi.
- Neurological disability is characterized by dystonia or other movement disorders like choreoathetosis, ballismus, spasticity and hyperreflexia.
- Behavioral abnormalities include intellectual disability and aggressive and impulsive behaviors.
- Hypoxanthine guanine phosphoribosyltransferase (HPRT) that plays a key role in recycling purine bases is deficient in these individuals due to mutation of HPRT gene on X chromosome.
- Prognosis is bad as the treatment options are limited.
- Allopurinol is useful for treating hyperuricemia.
- Motor disabilities managed by baclofen and benzodiazepines and behavioral abnormalities managed by behavioral therapy and medications.

Calcium Pyrophosphate Dihydrate Deposition Disease/Pseudo-gout

Q. Write short essay/note on pseudo-gout; calcium pyrophosphate dihydrate deposition disease; pyrophosphate arthropathy.

Calcium pyrophosphate dihydrate (CPPD) deposition disease is a condition associated with deposition of calcium pyrophosphate dihydrate (CPPD) crystals within articular and hyaline cartilage.

Common Causes

See **Box 8.19**.

Box 8.19: Common causes of calcium pyrophosphate dihydrate crystal deposition disease.

- Idiopathic (most frequent): Occurs in association with aging
- Complication of primary osteoarthritis
- Long-term consequence of mechanical joint trauma or knee meniscectomy
- Familial
- Associated with systemic metabolic disease, e.g. hyperparathyroidism, dialysis-dependent renal failure, hemochromatosis, hypomagnesemia.

Clinical Features

- May be asymptomatic or may result in a variety of clinical presentations.
- A **common presentation** is **acute inflammatory arthritis** that resembles acute gout. Hence, also known as '**pseudogout**'. However, in contrast to gout it is more common in elderly women and usually affects the knee followed by the wrist, shoulder, ankle and elbow. Examination of joint reveals a warm, tender erythematous joint with signs of a large effusion. Fever is common.
- **Trigger factors:** These include trauma, intercurrent illness and surgery.
- **Chronic arthropathy:** It may also occur in association with CPPD crystal deposition disease.

Investigations

- **Examination of synovial fluid:** CPPD crystals can be demonstrated using compensated polarized microscopy and helps in differentiation from gout. CPPD crystals are generally **rhomboid-shaped and positively birefringent.** They appear blue when parallel to the long axis of the compensator and yellow when perpendicular. The synovial fluid is turbid and may be uniformly blood-stained.
- **X-rays of the affected joint:** It may show calcification in hyaline cartilage and/or fibrocartilage (chondrocalcinosis).

Basic Calcium Phosphate Crystal Deposition

- Basic calcium phosphate (BCP) deposition disease is due to the deposition of **hydroxyapatite or apatite crystals** and other basic calcium phosphate salts (e.g. octacalcium phosphate, tricalcium phosphate) in soft tissues.
- **Main sites of deposits:** BCP crystal deposits are mainly seen in tendons, ligaments and hyaline cartilage. In the shoulder, it may manifest as calcific tendinitis of the rotator cuff.
- **Fluids for crystal detection:** BCP crystals may be detected as **nonbirefringent globular clumps within leukocytes** in synovial and bursal fluids. Under light microscopy BCP crystal clumps stain positive with the calcium-binding dye such as alizarin red S.

Therapeutics for Crystal Deposition Disease

See **Table 8.31**.

TABLE 8.31: Therapeutics for crystal deposition disease.

➢ NSAIDs or COX-2 inhibitors ➢ Intra-articular corticosteroids ➢ Systemic corticosteroids ➢ ACTH ➢ Prophylactic low-dose colchicine ➢ Methotrexate for refractory chronic inflammation and recurrent pseudogout ➢ Oral magnesium (for patients with hypomagnesemia)	**Novel therapy** ➢ Phosphocitrate ➢ Caspase-1 or IL-1 antagonism for CPPD crystal-induced inflammation. Hydroxychloroquine for refractory chronic inflammation ➢ TLR2 antagonism for CPPD-associated degenerative arthropathy ➢ Oral calcium supplementation to suppress PTH levels ➢ ANKH anion channel blockade (probenecid) ➢ NPP1 inhibition ➢ TG2 inhibition ➢ Polyphosphates ➢ Promotion of crystal dissolution by alkaline phosphatase or polyamines

MISCELLANEOUS

Relapsing Polychondritis (RP)

- **Immune-mediated** condition associated with **inflammation in cartilaginous structures and other connective tissues** throughout the body.
- **Sites:** These include **ears**, nose, joints, respiratory tract, and others. Unilateral or bilateral external ear inflammation that characteristically spares the earlobe, episcleritis, scleritis, nasal bridge collapse, larynx and tracheal involvement with respiratory distress is seen.
- The **McAdam's criteria** require at least three criteria out of six of the following: 1) bilateral auricular chondritis, 2) non-erosive seronegative polyarthritis, 3) nasal chondritis, 4) ocular inflammation, 5) respiratory tract chondritis, and 6) cochlear and/or vestibular dysfunction.
- **Associated with diseases:** Thirty percent occur in association with disease such as systemic vasculitis (particularly Wegener granulomatosis), connective tissue disorder (e.g. rheumatoid arthritis or systemic lupus erythematosus), or a myelodysplastic syndrome.
- **Presentation:** Patients can present with respiratory obstruction, aortitis and mitral regurgitation.

Treatment: Steroids and in severe disease immunosuppressive agents (dapsone, methotrexate) are used.

Nonarticular Rheumatism

Q. Differentiate articular from nonarticular disorders.

- Nonarticular rheumatism is not actually a true arthritis. It refers to aches and pains that arise from structures outside of joints.
- **Forms:** Four forms namely **tendinitis, bursitis, FMS (fibromyalgia syndrome), and the myofascial pain syndrome.**
- **Common types of tendinitis and bursitis:**
    1. **Tennis elbow:** Pain over the lateral epicondyle of the elbow due to inflammation of the tendons of the wrist extensor muscles that insert at this location.
    2. **Golfer's elbow:** Pain over the medial epicondyle due to inflammation of the wrist flexor tendons that insert at this location.

3. **Shoulder impingement syndrome:** It is due to impingement of the tendons of the rotator cuff with shoulder abduction or flexion. It can be associated with supraspinatus tendinitis, subacromial bursitis, or rotator cuff tears.
4. **Housemaid's knee:** It is prepatellar bursitis produced due to repetitive trauma or overuse such as kneeling. Another common region for bursitis is over the greater trochanter of the lateral hip.

Fibromyalgia Syndrome

Q. Write short note on the criteria for diagnosis of fibromyalgia syndrome (FMS).

Fibromyalgia syndrome is characterized by chronic widespread pain, and is defined as pain for more than three months both above and below the waist.

- **Diagnostic criteria for FMS**
  - At least 3 months of widespread pain that is bilateral, above and below the waist.
  - It includes axial skeletal pain and pain to palpation at a minimum of 11 of 18 predefined tender points **(Fig. 8.18)**.
  - The diagnosis of other diseases does not exclude the diagnosis of FMS.

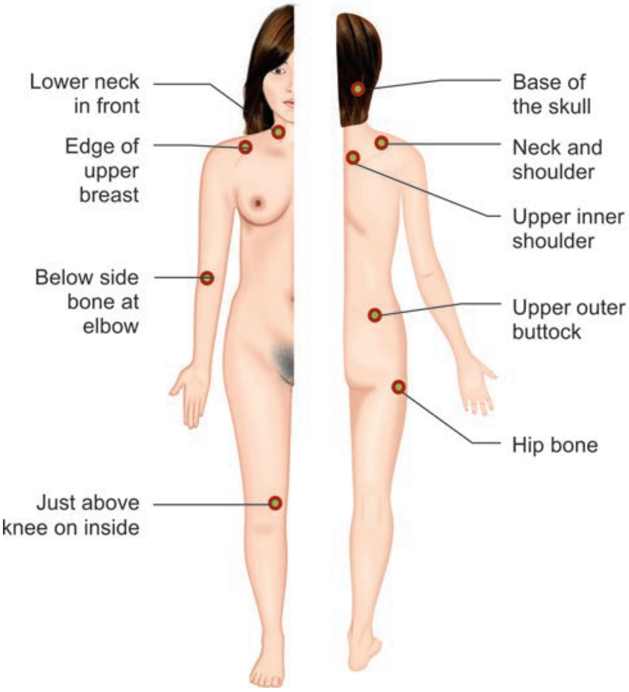

FIG. 8.18: Trigger points in fibromyalgia.

- **Physical examination:** Normal except for tender points in precise locations. Usually, these points are tender bilaterally.
  - **Tender points (Fig. 8.18)**: Typically located at the occiput, at the midportion of the trapezius, the origin of the supraspinatus, low anterior cervical region, second costochondral junction, lateral epicondyle, outer upper quadrant of the buttocks, greater trochanter region, and medial knee area.
- **Differential diagnosis:** Medical illnesses that may exhibit symptoms similar to those of FMS include: Celiac sprue, hepatitis C, hyperparathyroidism, hypothyroidism, and polymyalgia rheumatica (PMR).
- Nonpharmacological treatment includes patient education and initiation of exercises.
- Amitriptyline, duloxetine, milnacipran, or pregabalin can be used as mono or combination therapy.

OSTEOPOROSIS

Q. Describe the risk factors, prevention and treatment of osteoporosis.

Osteoporosis is the most common bone disorder and is a component of the fragility syndrome.

Definition

- It is a bone disease characterized by low bone mass and micro-architectural disruption of bone tissue that leads to increased bone fragility and fracture risk.
- **WHO definition:** Osteoporosis is defined as a bone mineral density (BMD) of 2.5 standard deviations (SDs) below the young healthy adult mean value (T-score ≤ -2.5) or lower as measured by DXA (dual-energy X-ray absorptiometry). The term 'established osteoporosis' includes the presence of a fragility fracture. There is inverse relationship between bone mineral density and fracture risk in postmenopausal women and older men. However, this definition should not be applied to young women, men or children.
- **National Institute of Health (NIH) definition:** Osteoporosis is defined as a skeletal disorder characterized by compromised bone strength, which predisposes an individual to an increased risk of fracture.
- **Osteopenia:** It is the term used when the BMD values lies between –1 and –2.5 SDs below the young adult mean.

Epidemiology

Most common bone disorder. More common in women (4:1). More common in Caucasian population than in other races.

Pathogenesis

- In osteoporosis, there is **loss of bone mass,** despite **normal mineralization. In contrast, *osteomalacia*** occurs when **bone is not being properly mineralized,** despite the normal production of bone matrix.
- Osteoporosis develops due to an **imbalance in bone remodeling**. It can be due to increased breakdown of bone (**absorption of bone)** by osteoclasts and/or decreased bone formation by osteoblasts. The process of **mineralization of new bone matrix** remains normal.
- Osteoporosis affects both **trabecular** (long thick bones, e.g. femur) and **cortical bone** (high surface area, think bones, e.g. spine). When it affects trabecular bones, **reabsorption of bone** is the main mechanism.
- Genetic factors play an important role and multiple genes are involved, including collagen type 1A, vitamin D receptor and estrogen receptor genes.
- Nutritional factors, sex hormone status and physical activity also play a role. Cigarette smoking is an independent risk factor.

Classification of Osteoporosis

- **Generalized osteoporosis (Table 8.32):** It involves the entire skeleton. It may be:
  - **Primary** or
  - **Secondary** to variety of conditions
- **Localized:** Limited to certain bone or region (e.g. disuse osteoporosis of a limb).

Clinical Features

- **Risk of fracture:** Osteoporosis can be clinically silent and does not have specific symptoms. However, it increases the risk of bone fractures and fracture is the only cause of symptoms and thereby **increases the morbidity and mortality** in elderly.
- **Fragility fracture:** It is a low-trauma fracture, i.e. mechanical forces (situations) that would not ordinarily result in fracture in healthy people. They typically occur in trabecular bone. The most common sites are:
  - **Spine (vertebrae):** Sudden severe back pain (in the spine) that radiates around to the front suggests **vertebral crush fracture** (compression fracture).
  - **Hip (proximal femur):** Fractures of the **proximal femur** usually occur in elderly person falling on their side or back. Usually requires prompt surgery.
  - **Wrist (distal radius): Colles' fractures** follow a fall on an outstretched arm.
  - Other sites include arm (humerus), pelvis, ribs, and other bones.

Investigations and Diagnosis

Conventional plain radiograph: It is useful along with CT or MRI, for detecting complications of osteopenia (reduced bone mass; pre-osteoporosis), such as fractures. However, radiography is relatively insensitive for detection of early disease as it requires a substantial amount of bone loss (about 30%) to be apparent on X-ray images. The radiographic features of osteoporosis are cortical thinning and increased radiolucency.

TABLE 8.32: Causes of generalized osteoporosis

Primary
- Idiopathic
- Postmenopausal
- Senile

Secondary
- Endocrine disorders
  - Addison disease
  - Type 1 diabetes mellitus
  - Hyperparathyroidism
  - Hyperthyroidism
  - Hypothyroidism
  - Pituitary tumors
  - Cushing's syndrome
  - Acromegaly
- Hypogonadal states
  - Turner's syndrome
  - Klinefelter's syndrome
  - Female hypogonadism
  - Premature and primary ovarian failure
  - Anorexia nervosa
  - Hypothalamic amenorrhea
  - Hyperprolactinemia
- Nutritional and gastrointestinal disorders
  - Hepatic insufficiency, severe liver disease, especially biliary cirrhosis
  - Pernicious anemia
  - Subtotal gastrectomy
  - Malabsorption syndromes
  - Malnutrition
  - Parenteral nutrition
  - Vitamin C, D deficiencies
- Rheumatologic disorders
  - Rheumatoid arthritis
  - Ankylosing spondylitis
- Hematologic disorders/malignancy
  - Multiple myeloma
  - Lymphoma and leukemia
  - Malignancy with parathyroid hormone (PTHrP) production
  - Hemolytic anemias (e.g. thalassemia)
  - Systemic mastocytosis
  - Hemophilia
  - Disseminated carcinoma
- Drugs
  - Alcohol
  - Anticoagulants (e.g. heparin)
  - Anticonvulsants
  - Chemotherapy
  - Corticosteroids
  - Proton pump inhibitors
  - Ciclosporin, tacrolimus
- Miscellaneous
  - Homocystinuria
  - Immobilization
  - Osteogenesis imperfecta
  - Pulmonary disease

Bone biopsy: Tetracycline labeling of the skeleton on bone biopsy determines the rate of skeletal growth. However, the current use of BMD tests, in combination with hormonal evaluation and biochemical markers of bone remodeling, has replaced the bone biopsy.

Biochemical markers: They provide an index of the overall rate of bone remodeling. Markers for bone formation include serum bone-specific alkaline phosphatase, serum osteocalcin, serum propeptide of type I procollagen. Markers for bone resorption urine and serum cross-linked N-telopeptide, urine and serum cross-linked C-telopeptide and urine total free deoxypyridinoline.

Bone mineral density (BMD): It is a measure of the mineral content of bone. It is mostly calcium, but also comprises potassium, manganese, magnesium, strontium, selenium, and other minerals. The diagnosis of osteoporosis can be made by measuring the bone mineral density (BMD).

- **Dual energy X-ray absorptiometry (DXA):** It is the most commonly used technique to measure BMD. Two low dose X-rays are directed to the area of interest. It measures areal bone density (mineral/surface area rather than a true volumetric density), usually spine (lumbar) and hip (proximal femur). It uses low doses of radiation and is the 'gold standard' for the diagnosis of osteoporosis. Results from DXA are expressed as either the T-score or the Z-score.

- T-score that is 2.5 SD or more below the young adult mean BMD is defined as osteoporosis, provided that other causes of low BMD have been ruled out (such as osteomalacia)
- T-score that is 1 to 2.5 SD below the young adult mean is termed low bone mass (osteopenia)
- Normal bone density is defined as a value within 1 SD of the mean value in the young adult reference population
- Z-score is a comparison of the patient's BMD to an age-matched population
- A Z-score of -2 or lower is considered below the expected range for age

- **Quantitative ultrasound:** This has many advantages in assessing osteoporosis being quick, easy and cheaper than other methods and does not need ionizing radiation. It is used as a screening procedure prior to DXA assessment and is not used for diagnostic purposes. The calcaneus is the most common skeletal site for quantitative ultrasound assessment.
- **Quantitative CT scanning:** It assesses true volumetric mineral density in mg/cm^3. It gives separate estimates of BMD for trabecular and cortical bone. It is more expensive and requires higher radiation than other techniques.
- **Other investigations:** These may be necessary to exclude other diseases or identify contributory factors associated with osteoporosis. These include complete blood count, thyroid function test, vitamin D levels and myeloma screen. Additionally renal function test, serum calcium, phosphorus, serum PTH, cortisol may be indicated.

Treatment of Osteoporosis

The aim of treatment is to reduce the risk of fracture. Treatment plan for osteoporosis includes: (1) diagnosis of individuals at highest risk, (2) exclusion of secondary causes of osteoporosis and (3) selecting appropriate treatment.

Prevention

Lifestyle changes: Methods to prevent osteoporosis include:

- **Nutrition:** Sufficient daily **calcium** intake (1200–1500 mg/day) and vitamin D.
- **Cessation of smoking.**
- Reduction in alcohol intake.
- **Increase weight bearing exercise:** They increase bone mass density and also helps to prevent falls. At least 30 minutes weight bearing exercise 3x per week is needed to increase bone density. Osteoporosis orthosis helps to prevent spine fractures and support the building up of muscles.
- Fall prevention can help prevent osteoporosis complications.

Pharmacological Management

Q. Write short note on drugs used in osteoporosis.

Drug treatments can reduce the risk of fracture **by up to 50%**.

The two main classes of drugs used namely: 1) antiresorptive agents and 2) anabolic agents.

1. ***Antiresorptive agents:*** They block bone resorption by inhibiting the activity of osteoclasts. These include bisphosphonates, denosumab, raloxifene, and calcitonin.
   - **Bisphosphonates:** These drugs are essentially analogues of pyrophosphate and include alendronic acid, risedronate, clodronate, pamidronate, etidronate. Usually taken **weekly**, and with plenty of water. **Poorly absorbed from the gut.**
     - Should be taken on an empty stomach, as they can bind to calcium in food, after which, the drug cannot be absorbed.
     - Only about 10% of the oral dose is absorbed under normal circumstances.

    - **Adverse drug reactions:** GI upset, esophagitis, bone pain, headache and fever rarely osteonecrosis of jaw. Oral and IV bisphosphonates should not be used in CKD and eGFR <30 to 35 mL/min.
  - **Hormone-replacement therapy (HRT)**
    - No longer used as mainstream treatment. Used if other treatments are not tolerated or effective.
    - It may be useful in women in post-menopausal osteoporosis. Most effective when started early in menopause, and to be continued for >5 years.
    - Disadvantages: (1) Bone loss continues, and is possibly increased upon stopping HRT and (2) increases the risks of cardiovascular disease and stroke.
    - Estrogen analogs: Estrogen replacement therapy is good for prevention of osteoporosis. However, it is not recommended unless there are other indications for its use. In hypogonadal men testosterone has been shown to give improvement in bone quantity and quality.
    - **Raloxifene, Bazedoxifene:** It is a selective estrogen receptor modulators (SERMs) that act on the estrogen receptors throughout the body in a selective manner. Raloxifene has an advantage of reducing the risk of invasive breast cancer. SERMs have been proven effective in clinical trials.
  - **Calcitonin:** It directly inhibits osteoclastic bone resorption activity via the calcitonin receptor on the surface of osteoclasts. It acts by inhibiting actin cytoskeleton which is needed for the osteoclastic activity.

2. ***Bone anabolic agents:*** They stimulate bone formation by acting primarily on osteoblasts. These include parathyroid hormone and teriparatide.
   - **Teriparatide and abaloparatide:** It acts like parathyroid hormone and stimulates osteoblasts and increases their activity. Mostly used for patients with established osteoporosis, those with low BMD or several risk factors for fracture or cannot tolerate the oral bisphosphonates. It is given as a daily injection with the use of a pen-type injection device.
   - **Sodium fluoride:** It produces skeletal changes such as pronounced bone density with increased number and thickness of trabeculae, cortical thickening, and partial obliteration of the medullary space.
3. ***Other agents***
   - **RANKL inhibitors: Denosumab** is a fully human monoclonal antibody that mimics the activity of osteoprotegerin. It binds to RANKL, thereby preventing RANKL from interacting with RANK and reducing its bone resorption.
   - **Romosozumab,** a monoclonal anti-sclerostin antibody has been approved.
   - **Strontium ranelate:** It is an alternative oral treatment, belonging to a class of drugs called ‘dual action bone agents’ (DABAs). It has proven efficacy, especially in the prevention of vertebral fracture. Strontium ranelate is taken as a 2 g oral suspension daily.

Supplements: Dietary supplements are given as adjuncts to pharmacological therapy. These include **(1) calcium** and **(2) vitamin D.**

ANTIPHOSPHOLIPID ANTIBODY SYNDROME (HUGHES SYNDROME)

Q. Write short note on antiphospholipid antibody (APLA) syndrome and antiphospholipid antibodies.

- Antiphospholipid antibody (APLA) syndrome or antiphospholipid syndrome (APS) is characterized by the **presence of a family of antibodies** in the patient’s plasma known as antiphospholipid antibodies (autoantibodies directed against phospholipids) and a syndrome of **hypercoagulability.** This prothrombotic disorder is also associated with thrombocytopenia.
- *The term **antiphospholipid antibody is misleading** because these antibodies react with plasma proteins which themselves bind and form complexes with negatively charged phospholipids. So, in contrast to the terminology antiphospholipid, there is no direct binding of antibodies to phospholipids.*

Types of Antiphospholipid Antibody Syndrome

- **Primary antiphospholipid syndrome:** They do not have any predisposing cause and their only manifestation is hypercoagulable state.
- **Secondary antiphospholipid syndrome:** These are found in association with autoimmune diseases, like systemic lupus erythematosus. Because of this association, they were formerly known as lupus anticoagulant syndrome.

Clinical Features

It is the most common acquired hematologic cause of recurrent thromboembolic events. Clinical manifestations chiefly are due to a direct or indirect effect of venous or arterial thrombosis and/or pregnancy morbidity **(Table 8.33)**.

TABLE 8.33: Clinical manifestations of antiphospholipid antibody syndrome.

Organ/System	*Manifestation*
Venous thrombosis and related consequences	Deep vein thrombosis **Cutaneous:** Livedo reticularis **(Fig. 8.19)** **Lung:** Pulmonary embolism, pulmonary hypertension, superficial thrombophlebitis, thrombosis in various other sites
Arterial thrombosis and related consequences	**Neurologic:** Stroke, transient ischemic attack **Cardiac:** Myocardial ischemia (infarction or angina), valvular vegetation (Libman-Sacks endocarditis) **Cutaneous:** Leg ulcers and/or digital gangrene. Arterial thrombosis in the extremities **Ophthalmologic:** Retinal artery thrombosis/amaurosis fugax ischemia of visceral organs or avascular necrosis of bone Multi-infarct dementia
Neurologic manifestations of uncertain etiology	Migraine; epilepsy; chorea; cerebellar ataxia; transverse myelopathy
Renal manifestations	**Renal artery/renal vein/glomerular thrombosis,** renal microangiopathy, renal infarction, acute renal failure, hematuria
Osteoarticular manifestations	Arthralgia; arthritis
Obstetric manifestations	Preeclampsia; eclampsia
Fetal manifestations	Early fetal loss (<10 weeks); late fetal loss (10 weeks); premature birth among the live births
Hematologic manifestations	Thrombocytopenia, autoimmune hemolytic anemia
Others	Osteonecrosis, adrenal infarction
Catastrophic Antiphospholipid Syndrome ➢ History of APS and/or aPL. ➢ Three or more new organ thromboses within a week.	

Diagnosis

Types of antiphospholipid antibodies: Antiphospholipid antibodies are a heterogeneous group of autoantibodies directed against phospholipids-binding proteins. Many plasma proteins (e.g. prothrombin, b_2-glycoprotein) bind to anionic phospholipids resulting in different antiphospholipid antibodies. Antiphospholipid antibodies (APAs) may include (1) **lupus anticoagulant** (LA) **antibody,** (2) **anticardiolipin antibody** (aCL), or (3) **anti-b_2-glycoprotein-I** (anti-b_2-GPI) **antibody.**

1. **Lupus anticoagulant (LA) antibody:**
   - It is named lupus as it was first detected in patients with systemic lupus erythematosus (SLE).
   - It was called anticoagulant because it paradoxically prolongs the clotting times by coagulation assays in vitro (e.g. prolongation of APTT).
   - However, the term lupus anticoagulant is a misnomer, because it is more frequently found in patients without lupus and is not anticoagulant and is associated with a hypercoagulable state rather than bleeding.
   - For LA screening, two or more phospholipid-dependent coagulation tests are necessary. These include (1) activated partial thromboplastin time, (2) dilute Russell viper venom time *(DRVVT)* and (3) kaolin clotting time.
2. **Anticardiolipin antibody (aCL):** They target cardiolipin (a bovine cardiac protein) and are detected by immunoassays.
3. **Anti-β_2-glycoprotein-I (anti-β_2-GPI) antibody:** They are directed against β_2- glycoprotien I and may be causal in APLA syndrome.

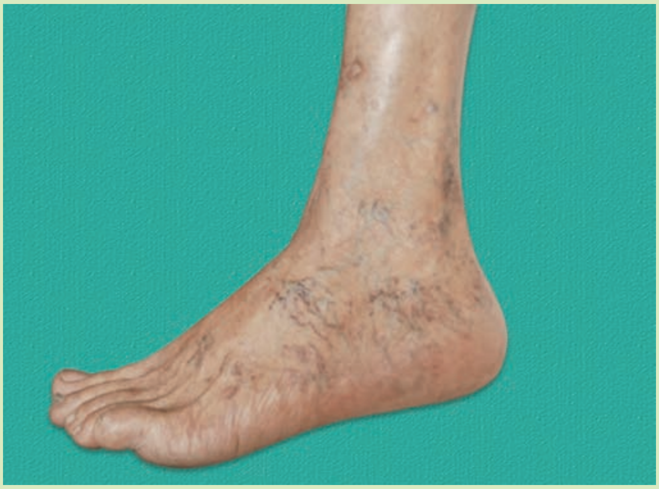

FIG. 8.19: Livedo reticularis-mottled reticulated vascular pattern that appears as a lace-like purplish discoloration of the skin. It is due to swelling of the venules caused by obstruction of capillaries.

Significance

- LA antibodies are more specific, whereas aCL antibodies are more sensitive for antiphospholipid syndrome. IgG aCL antibodies are more specific than IgM type.
- Antiphospholipid antibodies may be detected in 10% of normal population and 30–50% of SLE patients. They can also be found in patients with infections such as human immunodeficiency virus and during therapy with medications (e.g. chlorpromazine).

Criteria for Diagnosis: APLA Syndrome (Box 8.20)

Box 8.20: Antiphospholipid antibody syndrome classification criteria (revised **Sapporo classification criteria**).

Vascular thrombosis

- Arterial, venous, or small vessel

Pregnancy morbidity

- One or more fetal deaths
- One or more premature births due to severe preeclampsia or placental insufficiency
- Three or more first trimester losses

PLUS

- Lupus anticoagulant
- Anticardiolipin IgG or IgM (medium to high titer)
- Anti-beta$_2$ glycoprotein-1 IgG or IgM on two occasions 12 weeks (or more) apart
- A definite diagnosis of antiphospholipid syndrome is made if the patient has one clinical and one laboratory criteria.

Management

Treatment of Venous Thrombosis

- Patients with APS have a high risk of recurrent thromboembolism. Hence, they should receive antithrombotic therapy.
- **Anticoagulation** with unfractionated heparin or low-molecular-weight heparin (LMWH), and oral warfarin, for acute venous thromboembolism (VTE). This is followed by long-term oral warfarin to a target international normalized ratio (INR) of 2 to 3, alone or in combination with 80 mg of aspirin daily. Duration of treatment is probably lifelong.
- Catastrophic APSis treated with anticoagulation, glucocorticoids, and, in severe cases, plasma exchange and/or intravenous immune globulin (IVIG).

Prevention of Recurrence of Arterial Thrombosis

- Aspirin 325 mg/day or warfarin (INR between 1.4 to 2.8).

Prophylaxis of any Thrombotic Episode

- Aspirin for preventing thrombosis in females with previous pregnancy loss.
- Modification of other risk factors (e.g. hypercholesterolemia, smoking).

Management of Pregnancy in patients with Antiphospholipid Syndrome

- **Attempted conception:** Start aspirin 80 mg daily.
- **Confirmed intrauterine pregnancy** by ultrasound, start heparin (5,000–10,000 units every 12 hours) or low-molecular-weight heparin in prophylactic doses (enoxaparin 1 mg/kg, dalteparin 5000 units once a day) and continue till late in the third trimester.
- **Females with a history of pregnancy losses:** The goal is to prevent recurrent pregnancy loss. Two or more early pregnancy losses, or one or more late pregnancy losses without any previous history of thrombosis should receive combination of aspirin and heparin (unfractionated or low molecular weight) during pregnancy.

Treatment

- Intravenous heparin along with high-dose corticosteroids.
- Early addition of plasma exchange and/or intravenous immunoglobulin (400 mg/kg qd) or CD20 monoclonal antibody rituximab, ofatumumab, veltuzumab, and ocrelizumab (375 mg/m^2 per week for 4 weeks) in patients who do not respond promptly to heparin and corticosteroids.

Prognosis: Despite treatment, mortality is about 50%.

INFLAMMATORY MUSCLE DISEASES

Q. Discuss the clinical features of inflammatory muscle diseases.

Common Inflammatory Muscle Diseases (Table 8.34)

Idiopathic inflammatory myopathies consist of three major types: (1) **polymyositis,** (2) **dermatomyositis** and (3) **inclusion body myositis**.

TABLE 8.34: Common inflammatory muscle diseases.

	Autoimmune (idiopathic)	
Infective forms	***Generalized forms***	***Focal forms***
➢ Viral: Coxsackie B, influenza, Epstein-Barr virus, HIV ➢ Bacterial: *Streptococcus*, *Staphylococcus*, clostridia, mycobacteria ➢ Fungal: Candidiasis, coccidioidomycosis, cryptococcosis ➢ Protozoal: Toxoplasmosis ➢ Helminthic: Trichinosis, cysticercosis	➢ Dermatomyositis ➢ Polymyositis ➢ Inclusion body myositis ➢ Overlap syndromes ➢ Eosinophilic myositis ➢ Granulomatous myositis ➢ Necrotizing myopathy (paraneoplastic)	➢ Monomelic myositis ➢ Eosinophilic myositis ➢ Macrophagic myofasciitis ➢ Orbital myositis

Polymyositis and Dermatomyositis

Q. Write short note on polymyositis and dermatomyositis.

Differentiate polymyositis from dermatomyositis.

Idiopathic Polymyositis

Onset: Gradual. Commonly between 40 and 60 years of age.

Clinical Manifestations

- **Symmetrical proximal muscle weakness:**
    - **Sites affected:** Usually affects the **lower limbs** (hips and thighs) **than the upper limbs** (shoulder girdle muscles). The distal muscles, facial muscles are not usually affected.
- **Others:** Involvement of pharyngeal, laryngeal and respiratory muscles can lead to dysphonia and respiratory failure.
- Cardiac involvement (e.g., conduction disturbances, congestive heart failure) seen in 30%. Cannot rely on elevated CPK M/B fraction or troponin T, which are elevated in inflammatory muscle disease. Troponin I elevation is specific to cardiac involvement
- **Systemic features:** Fever, weight loss and fatigue are common.
- Increased risk of associated cancer in patients aged >40 to 50 years
- **Investigation:** Muscle biopsy shows endomysial more than perimysial inflammation surrounding and invading non-necrotic muscle fibers expressing major histocompatibility complex (MHC) class I antigens.

Idiopathic Dermatomyositis

Q. Write short note on dermatomyositis.

- Dermatomyositis characterized by **polymyositis** along **with** characteristic **skin changes**. The skin changes may occur before or after the muscle syndrome.
- **Skin changes:** These include:
    - **Gottron's papules:** Scaly, erythematous or violaceous, psoriasiform plaques occurring over the extensor surfaces of PIP and DIP joints.
    - **Heliotrope rash:** Violaceous discoloration of the eyelid may be seen along with periorbital edema.
    - **Shawl sign or the V sign:** Occurrence of erythematous macules distributed in a 'shawl' pattern over the upper back, chest and shoulders.
    - **Holster sign:** Poikiloderma on the lateral aspects of the thighs.
    - **Periungual telangiectasias:** Periungual nail-fold capillaries are enlarged and tortuous.
    - **Mechanic's hand:** Fissured, scaly and hyperkeratotic hand (in cases of antisynthetase syndrome).
- **Others:** Ulcerative vasculitis and calcinosis (calcium deposition) of the subcutaneous tissue seen in about 25% of cases. In the long-term, muscle fibrosis and contractures of joints occur.
- **Increased risk of malignancy:** Few patients with dermatomyositis above 60 years of age have an underlying malignancy. The most common being ovarian and gastric carcinoma, and lymphoma.
- **Amyopathic dermatomyositis or dermatomyositis sine myositis:** Presence of pathognomonic skin lesion without muscle involvement.
- **Investigation:** Muscle biopsy is must and shows necrosis of muscle (single fibers or in groups), perifascicular atrophy, and infiltration with lymphocytes.

Table 8.35 lists the differences between dermatomyositis, polymyositis and inclusion-body myositis.

TABLE 8.35: Differences between dermatomyositis, polymyositis and inclusion-body myositis.

Features	***Dermatomyositis***	***Polymyositis***	***Inclusion-body myositis***
Sex	F > M	M = F	M >> F
Age of onset	Any	20 years +	50 years +
Onset	Subacute/acute	Chronic	Chronic
Distribution of weakness	Proximal	Proximal	Proximal + distal + asymmetric (typically quadriceps + finger flexors)
Muscle pain/swelling	In acute cases	No	No
Skin involvement	Often	No	No
Raynaud's, Arthralgia	Frequent	Infrequent	No
Dysphagia	In severe cases	Infrequent	Occasional
Association with cancer	Up to 20%	Probably no	No
Cardiac involvement	Yes	No	No
Interstitial lung disease	Associated with anti-Jo	Associated with anti-Jo	No

Diagnosis

- **ESR** and **CRP:** Usually raised.
- **Serum autoantibody studies: Antinuclear antibodies** frequently positive.
- **Muscles enzymes:** Raised levels of **serum creatine kinase** (CK), **aldolase,** serum glutamic oxaloacetic transaminase (SGOT), lactate dehydrogenase (LDH) and serum glutamic pyruvate transaminase (SGPT).
- **Autoantibodies** directed against cytoplasmic RNA synthetases, other cytoplasmic proteins and RNP found in about 30% of patients. Only antihistidyl-tRNA synthetase (anti-Jo-1 antibody) is a diagnostic marker and is found in 20% of patients with polymyositis/dermatomyositis.
- **Electromyography (EMG):** It can confirm the presence of myopathy and exclude neuropathy.
- **MRI:** It can be used to detect abnormally inflamed muscle.
- **Needle muscle biopsy:** Characteristic changes—fiber necrosis, regeneration and lymphocytic inflammatory cell infiltrate. Open biopsy helps in more thorough assessment.
- **Screening for malignancy:** These include CXR (chest X-ray), mammography, pelvic/abdominal ultrasound, PET scan, urine microscopy and circulating tumor markers.

Management

- **Corticosteroids:** The treatment of choice is prednisolone (dose of 1 mg/kg daily) till patient shows significant improvement. High-dose intravenous methylprednisolone (1 g/day for 3 days) may be necessary in patients with respiratory or pharyngeal weakness.
- **Additional immunosuppressive therapy:** If no improvement with prednisolone, azathioprine (2–3 mg/kg/day) may be added. It also has some steroid-sparing effect. Other steroid-sparing agents include methotrexate, azathioprine, ciclosporin, cyclophosphamide mycophenolate mofetil, tacrolimus and MMF.
- **Intravenous immunoglobulin:** It may be effective in refractory or rapidly progressive cases.

CHAPTER 9

Hematology

DISORDERS OF RED BLOOD CELL

INTRODUCTION

Hemoglobin Structure

Q. BI5.2 Describe and discuss functions of proteins and structure-function relationships in relevant areas, e.g., hemoglobin and selected hemoglobinopathies.

A hemoglobin molecule is a conjugated protein composed of iron-containing pigment called **heme** and protein **globin**. About 65–70% of hemoglobin is synthesized in normoblasts and 30–35% is synthesized at the reticulocyte stage.

- Each molecule of **heme** consists of protoporphyrin with an iron in ferrous state (Fe^{++}). Heme synthesis occurs mainly in the mitochondria of normoblasts.
- Each **globin** chain is made up of **two pairs of distinct polypeptide** chains (composed of a number of amino acids) bound to a heme molecule.
    - **Hemoglobin A (HbA)** is composed of two α and two β globin chains ($\alpha_2 \beta_2$) and normally represents more than 95% of the hemoglobin in adult red blood cells (RBCs). Fetal hemoglobin is replaced by adult hemoglobin during the first year of life (hemoglobin switching).
    - **Fetal hemoglobin (HbF)** contains two α and two γ globin chains ($\alpha_2 \gamma_2$). It is the major hemoglobin (70–90%) during fetal development and is normally found in low levels in adults.
    - **Hemoglobin A2 ($\alpha_2 \delta_2$)** is normally found at low levels in adults (2%).
    - Normal hemoglobin in the adult are HbA ($\alpha_2 \beta_2$) and HbA_2 ($\alpha_2 \delta_2$)
    - Normal hemoglobin in the fetus are HbF ($\alpha_2 \gamma_2$) and Hb-Bart's (γ_4).

Red Cell Indices

- **Mean corpuscular volume (MCV):** It is used for classification and differential diagnosis of anemias.
    - **Normal range: 82–98 fL** (fL stands for femtoliters)

  Microcytic anemia has MCV <80 fL and macrocytic anemia has MCV >100 fL.
- **Mean corpuscular hemoglobin (MCH):**
    - **Normal range: 27–32 pg**

  MCH <26 pg is seen in microcytic anemia and MCH >33 pg is seen in macrocytic anemia.
- **Mean corpuscular hemoglobin concentration (MCHC):** It is a better indicator of hypochromasia than MCH.
    - **Normal range: 31–35 g/dL**

  MCHC <31 g/dL is seen in hypochromic RBC such as iron deficiency anemia (IDA) and thalassemia. MCHC is increased in hereditary spherocytosis.
- **Red cell distribution width (RDW):**
    - RDW is a quantitative measure of **anisocytosis**.
    - **Normal RDW is 11.5–14.5%.**

  RDW = (Standard deviation + mean cell volume) × 100
    - **Significance:** RDW is used for differentiating anemia due to iron deficiency and thalassemia. Increased in IDA (along with low MCV) and megaloblastic anemia (with high MCV) while in thalassemia trait, RDW is normal with low MCV.

  RBC count: Normal range in males 4.5–5.5 millions/mm^3; females 4–4.5 millions/mm^3

Reticulocyte Count

Reticulocytes are immature, non-nucleated RBCs released from bone marrow. They are demonstrated by using visual method brilliant cresyl blue/new methylene blue stain or by automated method which stain the remnant rRNA in the cytoplasm of these cells. Brilliant cresyl blue/new methylene blue stain are also known as supravital stain as it stains the reticulocytes vitally (when they are alive in unfixed blood sample) unlike other stains used after fixing of the blood smear with methanol. The automated method stains the RNA with a fluorescent dye.

Reticulocyte count is expressed as a percentage of RBC count (normal <2.5%). Reticulocyte count reflects the erythropoietic activity of the bone marrow and provides an estimate of red cell production. Increased erythropoiesis results in increased reticulocyte release. The reference range of the corrected reticulocyte percentage in adults is 0.5–1.5%. Causes of increased and reduced reticulocyte count are listed in **Table 9.1**.

TABLE 9.1: Causes of increased and reduced reticulocyte count.

Causes of increased reticulocyte count (reticulocytosis)	***Causes of reduced reticulocyte count***
➢ Hemolytic anemias ➢ Hemolytic crisis ➢ Hemorrhage ➢ Following treatment in iron/folic acid/vitamin B_{12} deficiency anemias. *Highest counts are found on 6th/7th day of treatment and indicate marrow response to iron and 3rd day in response to vitamin B_{12}*	➢ Due to decreased erythropoietic activity ➢ Aplastic anemia ➢ Aplastic crisis due to parvovirus (in hereditary spherocytosis and sickle cell disease) ➢ Pure red cell aplasia ➢ Fanconi anemia ➢ Myelofibrosis

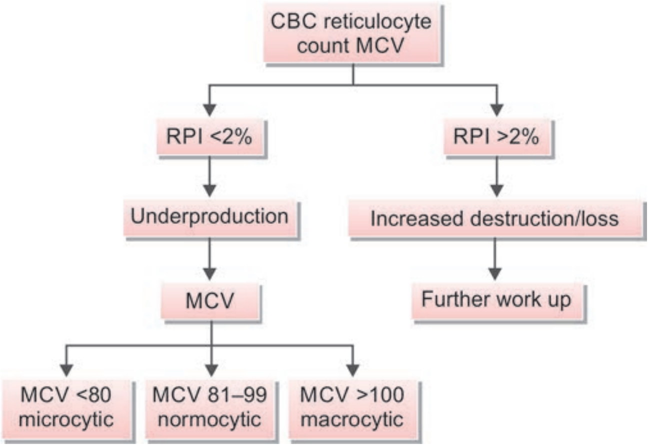
- **Reticulocyte production index (RPI)** is expressed as % and it accounts for premature release of reticulocytes from bone marrow in anemia. It is important in determining if a patient's bone marrow is responding appropriately to the level of anemia.

$$\text{Reticulocyte index} = \text{Reticulocyte count} \times \frac{\text{Hematocrit}}{\text{Normal hematocrit for the age}}$$

$$\text{Reticulocyte production index (RPI)} = \text{Reticulocyte count} \times \frac{\text{Hematocrit}}{\text{Normal hemoglobin for the age}} \times 0.5$$

Significance: Normal RPI is 1.0–2.0. However, RPI <2 with anemia indicates decreased RBC production (hypoproliferative anemia) and RPI >2 with anemia indicates hemolysis or loss of RBCs leading to compensatory production of reticulocytes and is observed in hyperproliferative anemia **Flowchart 9.1**.

Flowchart 9.1: Approach to anemia based on MCV and RPI.



RBC Abnormalities

Various RBC abnormalities are presented in **Figures 9.1 to 9.4**.

Q. Discuss the RBC abnormalities seen on a peripheral blood smear examination.

Q. IM9.1 Define, describe and classify anemia based on red blood cell size and reticulocyte count.

ANEMIA

Q. Describe and discuss the morphological characteristics, etiology, and prevalence of each of the causes of anemia.

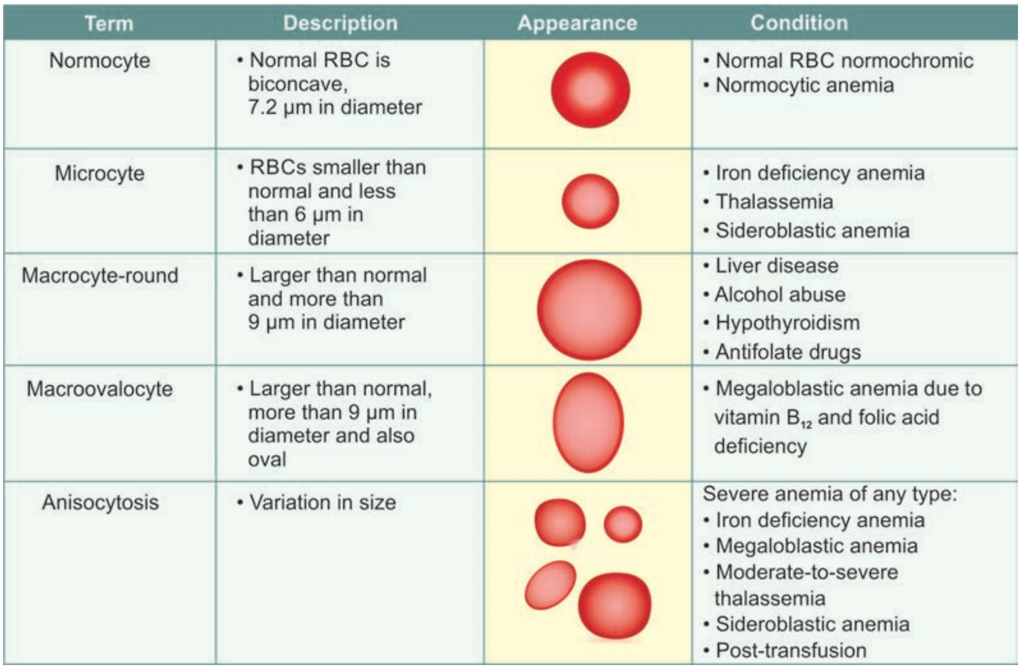
Definition

Anemia is defined as **decrease** in circulating red blood cell mass. It is characterized by decrease of **hemoglobin concentration (Hb)/RBC count/hematocrit (PCV)** below normal for the patient's age, sex, and altitude of residence.

Normal adult hemoglobin level is in the range of 13–17 g/dL in males and 12–15 g/dL in females.

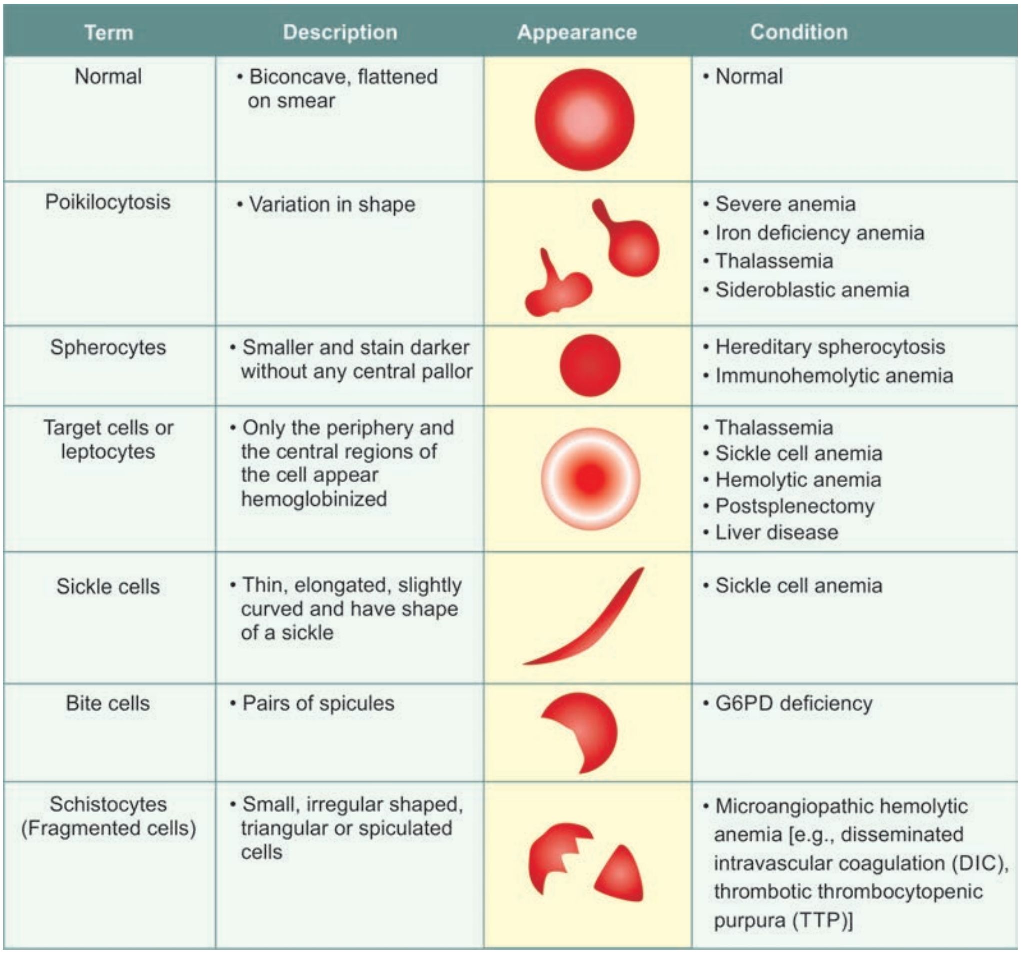
Classification of Anemia

Anemia may be classified (1) based on the morphology of red cells (morphological classification) and (2) based on the etiology/cause of anemia.



Term	Description	Appearance	Condition
Normocyte	• Normal RBC is biconcave, 7.2 µm in diameter		• Normal RBC normochromic • Normocytic anemia
Microcyte	• RBCs smaller than normal and less than 6 µm in diameter		• Iron deficiency anemia • Thalassemia • Sideroblastic anemia
Macrocyte-round	• Larger than normal and more than 9 µm in diameter		• Liver disease • Alcohol abuse • Hypothyroidism • Antifolate drugs
Macroovalocyte	• Larger than normal, more than 9 µm in diameter and also oval		• Megaloblastic anemia due to vitamin B_{12} and folic acid deficiency
Anisocytosis	• Variation in size		Severe anemia of any type: • Iron deficiency anemia • Megaloblastic anemia • Moderate-to-severe thalassemia • Sideroblastic anemia • Post-transfusion

FIG. 9.1: Variation in size of red blood cells and associated conditions.



Term	Description	Appearance	Condition
Normal	• Biconcave, flattened on smear		• Normal
Poikilocytosis	• Variation in shape		• Severe anemia • Iron deficiency anemia • Thalassemia • Sideroblastic anemia
Spherocytes	• Smaller and stain darker without any central pallor		• Hereditary spherocytosis • Immunohemolytic anemia
Target cells or leptocytes	• Only the periphery and the central regions of the cell appear hemoglobinized		• Thalassemia • Sickle cell anemia • Hemolytic anemia • Postsplenectomy • Liver disease
Sickle cells	• Thin, elongated, slightly curved and have shape of a sickle		• Sickle cell anemia
Bite cells	• Pairs of spicules		• G6PD deficiency
Schistocytes (Fragmented cells)	• Small, irregular shaped, triangular or spiculated cells		• Microangiopathic hemolytic anemia [e.g., disseminated intravascular coagulation (DIC), thrombotic thrombocytopenic purpura (TTP)]

FIG. 9.2A: Variation in shape of red blood cells and associated conditions.

Term	Description	Appearance	Condition
Acanthocytes/ spur cells	• RBCs with few spicules of uneven (irregular) length and shape		• Abetalipoproteinemia • Liver disease
Echinocyte/ Burr cells	• Very small irregular shrunken cells with pointed projections. Resemblance to the small thorny 'burrs'		• Uremia • Post-transfusion
Elliptocyte or Ovalocyte	• Oval in shape		• Hereditary ovalocytosis • Hemolytic anemia
Pencil shaped cells	• Elongated thin cells (exaggerated ovalocytes)		• Iron deficiency anemia
Tear drop and pear-shaped cells	• These abnormal RBCs have a teardrop or pear-like shape		• Myelofibrosis • Marrow infiltration
Stomatocytes	• Red cells with a slit-like area of central pallor		• Hereditary stomatocytosis • Liver disease

FIG. 9.2B: Variation in shape of red blood cells and associated conditions.

Term	Description	Appearance	Condition
Normochromic	Cell with 1/3 central pallor		• Normal RBC
Hypochromic	Central pallor more than 1/3		• Iron deficiency anemia • Thalassemia • Sideroblastic anemia
Polychromasia	Cells stained purple and are larger than normal		• Hemolytic anemias • Response to therapy in deficiency anemias

FIG. 9.3: Variation in color of red blood cells.

Term	Description	Appearance	Condition
Basophilic stippling (punctate basophilia)	• Red cells contain small, blue black inclusions and represent precipitated ribosomal RNA		• Lead poisoning • Megaloblastic anemias • Hemolytic anemias like thalassemias • Sideroblastic anemias • Alcoholism • Pyrimidine-5 nucleotidase deficiency
Howell–Jolly bodies	• Small, round, densely staining dark blue particles and represent nuclear remnants		• Megaloblastic anemias • Acute hemolytic anemias • Postsplenectomy state
Cabot rings	• Rings or figure of eight shaped and are probably remnants of the nuclear membrane		• Hemolytic anemia • Megaloblastic anemia • Leukemia • Rarely after splenectomy
Pappenheimer bodies/ siderotic granules (RBCs with Pappenheimer bodies are called siderocytes)	• Aggregates of ferritin and appear pale blue, but are easily demonstrable with Perl's stain (Prussian blue reaction)		• Sideroblastic anemias • Megaloblastic anemias • Hemolytic anemias • Postsplenectomy
Hemoglobin H inclusions	• Free β chains in red cells. Small, regular, multiple and diffusely distributed (golf ball like appearance). Stained by supravital stains		• α-thalassemias
Heinz bodies	• Refractive, single or multiple rounded inclusions of denatured globin detected by supravital stains		• Intake/exposure to oxidizing drugs or chemicals • G6PD deficiency • Unstable hemoglobin disease
Hemoglobin C crystals	• Crystallization of hemoglobin C		• Splenectomy in homozygous hemoglobin C

FIG. 9.4: Inclusions in red blood cells and associated conditions.

Morphological and Etiological Classification (Table 9.2)

Q. Write short essay/answer on etiology of anemia.

TABLE 9.2: Morphological classification.

Normocytic normochromic	Microcytic hypochromic	Macrocytic

Etiological classification	
Blood loss	
Acute	**Chronic**
Loss of large volume over short period **Trauma,** postpartum bleeding	Small volume over long period Peptic ulcer, hemorrhoids, carcinoma of colon, hookworms, excessive menstrual loss
Impaired red cell production	
Disturbed proliferation and maturation	**Marrow replacement**
Defective DNA synthesis ➢ Megaloblastic anemias—deficiency or impaired utilization of vitamin B_{12} and folic acid ➢ Anemia of renal failure—deficiency of erythropoietin ➢ Anemia of chronic disease—iron sequestration and relative erythropoietin deficiency ➢ Anemias of endocrine disorders ***Defective hemoglobin synthesis*** ➢ Defective heme synthesis: Iron deficiency, sideroblastic anemia ➢ Defective globin synthesis: Thalassemia	***Primary hematopoietic neoplasms*** ➢ Acute leukemia ➢ Myelodysplastic syndromes **Marrow infiltration (myelophthisic anemia)** ***Metastatic neoplasms*** **Disturbed proliferation and differentiation of stem cells** ➢ Aplastic anemia ➢ Pure red cell aplasia
Increased red cell destruction (hemolytic anemias)	
Intrinsic (Intracorpuscular)	**Extrinsic (Extracorpuscular)**
Hereditary ➢ Abnormal Membrane: Spherocytosis, elliptocytosis ➢ Enzyme deficiencies: Glucose-6-phosphate dehydrogenase, pyruvate kinase ➢ Disorders of hemoglobin synthesis – Deficient globin synthesis: Thalassemia – Hemoglobinopathies: Sickle cell anemia ***Acquired*** Membrane defects: Paroxysmal nocturnal hemoglobinuria	***Antibody-mediated*** ➢ Isohemagglutinins: Transfusion reactions, Rh disease of the newborn ➢ Autoantibodies: Idiopathic, primary, drug-associated, systemic lupus erythematosus ***Mechanical trauma to RBCs*** ➢ Microangiopathic hemolytic anemia: Disseminated intravascular coagulation ***Infections:*** Malaria

Clinical Features

Q. IM9.3 Elicit document and present a medical history that includes symptoms, risk factors including GI bleeding, prior history, medications, menstrual history, and family history.

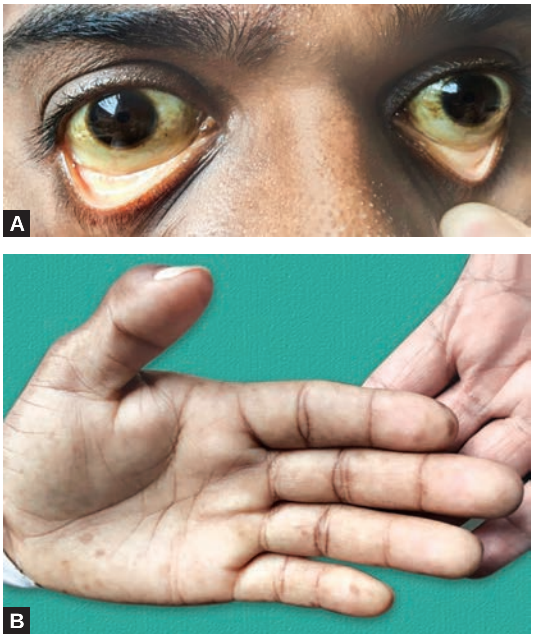
Symptoms

They depend on (1) speed of onset of anemia, (2) severity of anemia, (3) age of the patient, and (4) underlying illness. General clinical features are due to either tissue hypoxia or compensatory mechanisms.

- **Due to tissue hypoxia:**
    - Nonspecific symptoms: Weakness, malaise, lassitude, and easy fatigability
    - Dyspnea on mild exertion, angina, intermittent claudication, transient cerebral ischemia
    - Central nervous system (CNS): Headache, vertigo, tinnitus, dizziness, syncope, irritability, sleep disturbances, and lack of concentration
    - Gastrointestinal tract (GIT): Anorexia, indigestion, nausea, bowel disturbances
    - Female genital tract: Amenorrhea, polymenorrhea.
- **Due to compensatory mechanisms:** Cardiac features: Dyspnea on mild exertion, palpitation, tachycardia, and congestive cardiac failure.

Signs

- Pallor **(Figs. 9.5A and B)** is observed on skin, palms, mucous membranes (oral, vaginal, rectal), nail beds, and palpebral conjunctiva.
- Pulse: Tachycardia, wide pulse pressure



FIGS. 9.5A AND B: (A) Pallor of palpebral conjunctiva; (B) Pale palms with pale creases.

- Cardiovascular system (CVS): Cervical venous hum, hyperdynamic precordium, ejection systolic murmur (best heard over the pulmonary area), cardiac dilatation and later, signs of cardiac failure
- Ankle edema

Signs suggesting etiology of anemia (Table 9.3)

TABLE 9.3: Various signs of anemia suggesting the probable etiology.

Signs	*Probable etiology*
Angular cheilitis, blue sclera, koilonychia	Iron deficiency anemia
Glossitis	Iron, vitamin B_{12}, and folate deficiency anemia
Neurological changes (neuropathy, dementia, ataxia), knuckle pigmentation	Vitamin B_{12} deficiency
Jaundice	Hemolytic anemia, megaloblastic anemia
Splenomegaly	Malaria, chronic hemolytic anemia, acute infection, leukemia, lymphoma, portal hypertension, megaloblastic anemia, iron deficiency anemia (rare)
Frontal bossing, dental malocclusion, skin ulcers	Chronic hemolytic anemia (e.g., beta-thalassemia, sickle cell anemia)
Leg ulcers	Sickle cell disease

History in diagnosis of anemias (Table 9.4)

TABLE 9.4: History suggesting the possible etiology of anemia.

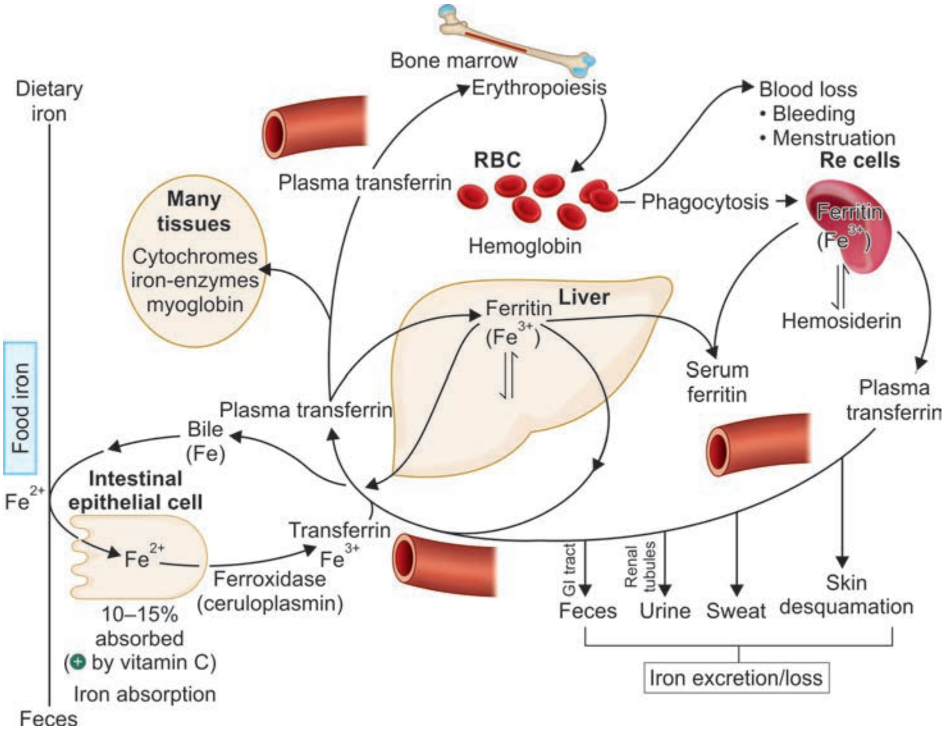
Signs and symptoms	*Possible etiology of anemia*
Known normal complete blood cell count in the past	Probably not a hereditary/congenital disorder
Anemia known since childhood	Inherited/congenital hemolytic anemia
Splenectomy, gallstones, and/or jaundice	Chronic hemolytic anemia, liver disease
Family history of splenectomy, gallstones, and/or jaundice	Hereditary hemolytic anemia (RBC enzyme or membrane disorder, thalassemia, or hemoglobinopathy)
Poor or unconventional diet, malnutrition, or severe alcoholism	Bone marrow hypoplasia, folate deficiency
Paresthesias, foot numbness, loss of balance, altered mental status	Cobalamin (vitamin B_{12}) deficiency
Gastrectomy, surgical removal of the ileum, chronic malabsorption disorder	Cobalamin (vitamin B_{12}) deficiency
Chronic gastritis, peptic ulcer disease, chronic use of ASA or NSAIDs, recurrent epistaxis or rectal bleeding, melena, menorrhagia, metrorrhagia, multiple pregnancies, duodenal surgery, gastrectomy	Iron deficiency
Chronic rheumatologic, immunologic, infectious, or neoplastic disease	Anemia of inflammation, autoimmune hemolytic anemia
Decreased urine output	Anemia secondary to renal insufficiency
Dark urine	Hemolytic anemia (intravascular hemolysis)
Recent onset of infections, mucosal and skin bleeding, easy bruising, oral ulcerations	Bone marrow aplasia/hypoplasia, acute leukemia, myelodysplasia, myelophthisis
Occupational/environmental toxin exposure (benzene, ionizing radiation, lead)	Bone marrow aplasia/hypoplasia, acute leukemia, myelodysplasia, lead poisoning
Drug/medication exposure:	
➢ Penicillin, cephalosporin, procainamide, quinidine, quinine, sulfonamide	Drug-induced immune hemolytic anemia
➢ Fava beans, dapsone, naphthalene	Oxidant-induced hemolysis (G6PD deficient)
➢ Cancer chemotherapeutic drugs (recent use)	Bone marrow aplasia/hypoplasia, oxidant damage, fluid retention/ dilutional anemia, megaloblastic anemia
➢ Cancer chemotherapeutic drugs (past use)	Bone marrow hypoplasia, myelodysplasia, acute myeloid leukemia
➢ Chloramphenicol, gold salts, sulfonamides, anti-inflammatory drugs	Bone marrow aplasia/hypoplasia
➢ Ethanol, chloramphenicol	Acute reversible bone marrow toxicity
➢ Methotrexate, azathioprine, pyrimethamine, trimethoprim, zidovudine, sulfa drugs, hydroxyurea, antimetabolites	Bone marrow aplasia/hypoplasia, megaloblastic anemia

IRON METABOLISM (FIG. 9.6)

Iron is required for synthesis of normal heme of hemoglobin. Its deficiency leads to decreased erythropoiesis and anemia.

Distribution of Iron

Iron is an essential metal present in the human body. The total body iron content (3–4 g) is divided into functional and storage compartments **(Table 9.5)**. Iron in the body is extensively recycled between the functional and storage pools.



Bone marrow

FIG. 9.6: Iron metabolism.

TABLE 9.5: Iron distribution in healthy young adults.

Pool	*Grams*	*%*
Functional		
Hemoglobin	2.5	68
Myoglobin	0.15	4
Transferrin (iron-binding blood plasma glycoprotein)	0.003	0.1
Iron-containing enzymes	0.02	0.6
Storage		
Ferritin and hemosiderin in tissue	1.0	27
Ferritin, serum	0.0001	0.004

- **Functional:** Approximately 80% (2.5 g) of the functional iron is present in hemoglobin. The remaining functional iron is found in myoglobin and iron-containing enzymes (catalase, cytochromes, and peroxidases).
- **Storage:** The storage pool contains 15–20% (0.5–1.5 g) of total body iron. Free iron is highly toxic because it can result in tissue damage due to its capacity to form free radicals. Therefore, iron is bound to protein and stored in the body in two forms, namely "**ferritin**" and "**hemosiderin**". The storage iron can be readily mobilized whenever there is increase in the requirements of iron, as may occur after blood loss. Two-third of the iron is stored as ferritin and one-third as hemosiderin.
    - **Ferritin** (Fe^{3+}) is a protein–iron complex (apoferritin + iron) found in all tissues but particularly in liver, spleen, bone marrow, and skeletal muscles. Very small amounts of ferritin circulate in the serum, the value normally being 15–300 μg/L. **Serum ferritin levels reflect the iron stores** and are a sensitive indicator of the amount of iron in the body. Serum ferritin level is usually below 12 μg/L in iron deficiency and it is very high (as high as 5,000 μg/L may be observed) in conditions associated with iron overload. Ferritin is water-soluble and not visible by light microscopy.
    - **Hemosiderin** is an aggregate of iron and protein which is found in the reticuloendothelial cells of bone marrow, spleen, and liver. It is formed when iron is in excess (amorphous iron deposition).

Daily requirements: The recommended dietary allowance 10–15 mg. The daily requirement in **adult males is 5–10 mg/day and in females 20 mg/day**.

Dietary sources: The diet contains iron either in the form of heme contained in animal products and/or nonheme iron in vegetables. Of 10–50 mg in the diet, only 10–15% is normally absorbed.

Iron Absorption

Site of absorption: Iron is absorbed from the **duodenum** and **proximal jejunum**. Iron balance is maintained mainly by regulating the dietary absorption of iron (by the synthesis of apoferritin within mucosal cells).

Transport of Iron

- **Transferrin:** Iron is transported in plasma by the iron transport protein **transferrin**, which is synthesized in the liver. The major function of plasma transferrin is to deliver iron to erythroid precursors for the synthesis of hemoglobin. In normal individuals, transferrin is about 33% saturated with iron, with an average serum iron level of 120 μg/dL in men and 100 μg/dL in women. Thus, the total iron-binding capacity of serum is in the range of 310–340 μg/dL. Unsaturated transferrin protects against infections (iron overload and infection).

- **Lactoferrin:** It binds iron in milk. It has an antimicrobial effect (protects newborns from gastrointestinal infections).
- **Haptoglobin:** It binds hemoglobin in the plasma.

Iron Excretion/Loss

Iron metabolism is unique as it is very efficiently utilized and reutilized by the body. There is no physiological regulated mechanism for iron excretion and 1–2 mg/day is lost by shedding of epithelial cells of GI tract, skin epithelial cells (by sweat), and renal tubules and by menstruation, pregnancy, multiple births, lactation, and bleeding.

Regulation of Iron Balance

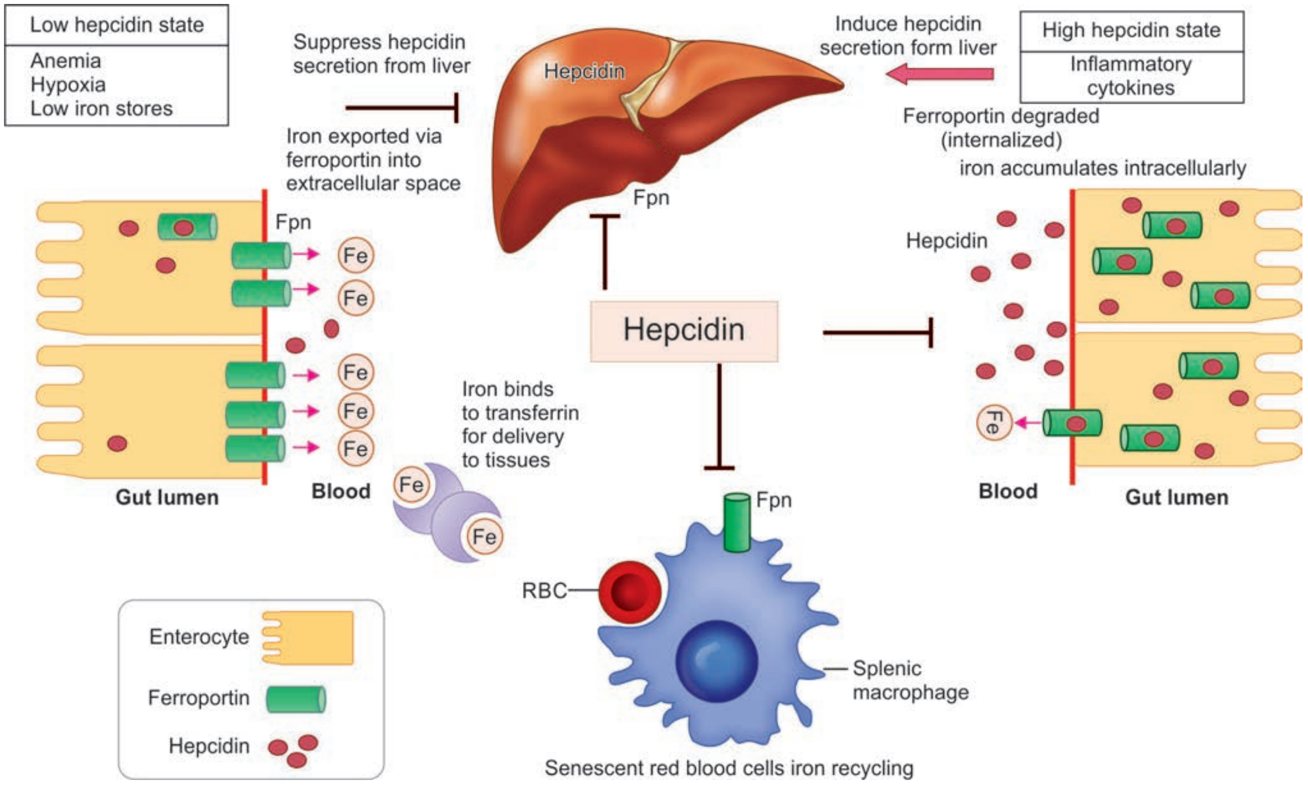
Iron is essential for cellular metabolism; at the same time, excess of it is highly toxic. Therefore, the total body iron stores must be properly regulated. Iron balance is mainly achieved by regulating the absorption of iron in the diet. As body stores decrease, the absorption of iron rises and vice versa.

Hepcidin

Q. Write a short note on the role of hepcidin.

It is synthesized in the liver and is the **central** (key) **regulator of iron homeostasis** and it **controls** intestinal iron **absorption,** plasma iron concentrations, tissue iron distribution, and **storage**.

- Ferroportin is the cellular iron exporter which exports iron into plasma
    - from absorptive enterocytes,
    - from macrophages that recycle the iron of senescent erythrocytes, and
    - from hepatocytes that store iron.
- The major mechanism of hepcidin is the regulation of transmembrane iron transport. Hepcidin binds to ferroportin and forms hepcidin–ferroportin complex. This complex is degraded in the lysosomes and thus degrades its receptor ferroportin. By this mechanism, hepcidin reduces resorption of iron in the intestine and inhibits iron transfer from the enterocyte to plasma (thereby reduces concentration of iron in plasma).
- When hepcidin levels rise, it lowers iron absorption in the intestine, iron gets stored (locked) within enterocytes forming mucosal ferritin, and iron is shed with the cells. It also lowers iron release from hepatocytes and macrophages (through degradation of ferroportin) leading to decreased serum iron. Actions of hepcidin are presented in **Figure 9.7**.



Low hepcidin state
Anemia
Hypoxia
Low iron stores
Suppress hepcidin secretion from liver
Iron exported via ferroportin into extracellular space
Hepcidin
Induce hepcidin secretion form liver
High hepcidin state
Inflammatory cytokines

Ferroportin
Hepcidin

FIG. 9.7: Actions of hepcidin.

Significance of hepcidin

- Increased hepcidin concentration is seen in inflammation (chronic disease anemia)
- Reduced hepcidin production → hereditary hemochromatosis.
- The **hepcidin mimetic**, **rusfertide**, for treating polycythemia vera patients is in phase 3 trial.

Functions of Iron

1. **Heme iron:** Hemoglobin, myoglobin, cytochrome c oxidase, catalase
2. **Nonheme iron:** Fe-S complexes (xanthine oxidase), DNA synthesis (ribonucleotide reductase).

IRON DEFICIENCY ANEMIA (IDA)

Q. Discuss the etiology, clinical features, investigations, and management of iron deficiency anemia.

Etiology (Table 9.6)

TABLE 9.6: Causes of iron deficiency anemia.

Decreased iron intake ➢ Milk-fed infants ➢ Elderly with improper diet, poor dentition ➢ Low socioeconomical sections ➢ Vegetarians (poorly absorbable inorganic iron)	**Increased demand/requirement for iron** ➢ Rapid growth in infancy or adolescents ➢ Pregnancy and lactation
Decreased absorption of iron ➢ Total/partial gastrectomy ➢ Intestinal absorption is impaired in sprue, other causes of intestinal steatorrhea, and chronic diarrhea ➢ Specific items in the diet, such as phytates of cereals, tannates, carbonates, oxalates, phosphates, and drugs, can impair iron absorption	**Increased iron loss** ➢ Chronic blood loss due to bleeding from the: ➢ Gastrointestinal tract (peptic ulcers, gastric or colonic carcinoma, hemorrhoids, hookworm infestation, schistosomiasis, or NSAID) ➢ Urinary tract (renal or bladder tumors) ➢ Genital tract (menorrhagia, uterine cancer)
Iron refractory iron deficiency anemia (IRIDA) is a rare inherited disorder caused by loss-of-function mutations of the *TMPRSS6/matriptase 2* gene.	

- IDA is due to deficiency of iron causing defective **heme synthesis**. Iron deficiency anemia is the most common cause of anemia.
- Daily requirement of iron is 10–15 mg. Children consuming large amounts of cow milk develop IDA because iron from cow milk is poorly absorbed and calcium in the milk inhibits iron absorption.

Stages of Iron Deficiency (Fig. 9.8)

- **Stage 1: Negative iron balance** is characterized by decreased bone marrow iron stores.
- **Stage 2: Iron-deficient erythropoiesis**—erythropoiesis is impaired when serum iron falls to <50 mcg/dL (<9 μmol/L) and transfers saturation to <16%.
- **Stage 3: Iron deficiency anemia**—microcytosis and then hypochromia develop. Eventually iron deficiency affects tissues, resulting in symptoms and signs.

	Normal	Negative iron balance	Iron-deficient erythropoiesis	Iron-deficiency anemia
Marrow iron stores	1–3+	0–1+	0	0
Serum ferritin (μg/L)	50–200	<20	<15	<15
TIBC (μg/dL)	300–360	>360	>360	>400
SI (μg/dL)	50–150	NL	<50	<30
Saturation (%)	30–50	NL	<20	<10
Marrow sideroblasts (%)	40–60	NL	<10	<10
RBC protoporphyrin (μg/dL)	30–50	NL	>100	>200
RBC morphology	NL	NL	NL	Microcytic/ hypochromic

FIG. 9.8: Stages of iron deficiency.

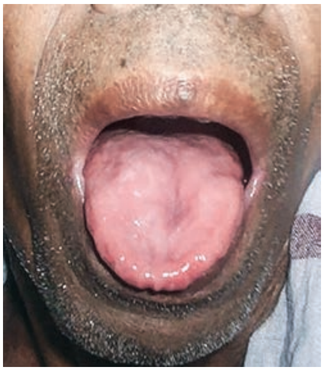

FIG. 9.9: Atrophic glossitis producing bald tongue in iron deficiency anemia. There is also mild cheilosis.

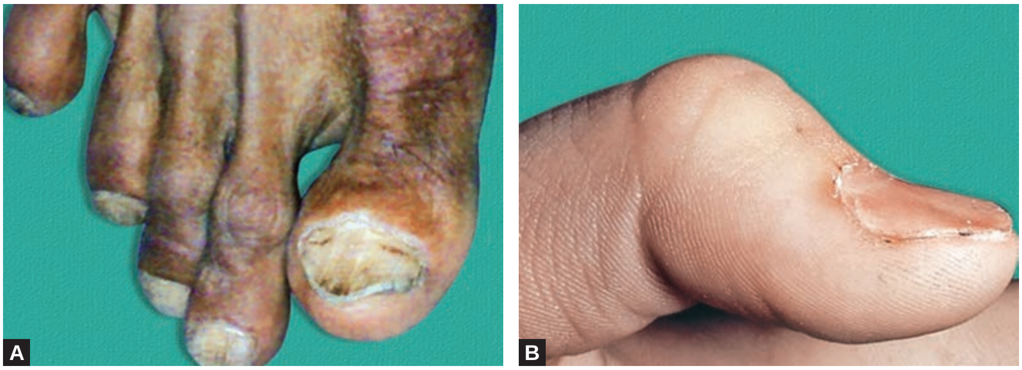

FIGS. 9.10A AND B: Koilonychia (Spooning of the fingernails) in iron deficiency anemia.

Q. Discuss the clinical manifestations and complications of iron deficiency anemia.

Q. Write a short note on Plummer–Vinson syndrome.

Clinical Features

- Clinical features of iron deficiency anemia include the usual symptoms and signs of anemia
- Characteristic signs of advanced iron deficiency include:
  - Cheilosis (fissures at the corners of the mouth)/angular stomatitis
  - **Atrophic glossitis (Fig. 9.9)**
  - Brittle fingernails, platonychia, and ***koilonychia*** (spooning of the fingernails) **(Figs. 9.10A and B)**, brittle hair
  - **Blue-tinged sclera,** alopecia
  - **Pica** is the unusual craving for substances which have a "crunching" sound with no nutritional value like clay or chalk. Craving for ice (pagophagia) specific to iron deficiency or less commonly for clay (geophagia) or starch (amylophagia); pagophagia is believed to be the most specific to iron deficiency.
- **Restless leg syndrome** is seen in around 25% of patients with IDA.
- **Beeturia** is a phenomenon in which the urine turns red following ingestion of beets. Beeturia is increased in individuals with iron deficiency (49–80% of individuals with iron deficiency).

Plummer–Vinson syndrome or Patterson-Brown-Kelly or **sideropenic dysphagia** develops in long-standing iron deficiency.

- Iron deficiency (microcytic hypochromic) anemia
- Atrophic glossitis
- Esophageal/postcricoid webs resulting in dysphagia for solids than liquids. The web can be demonstrated either by endoscopy or by barium swallow.
- These patients have increased risk of squamous cell carcinoma of pharynx and esophagus.

Diagnosis of Iron Deficiency Anemia

Q. IM9.8 Describe and discuss the various tests for iron deficiency.

Laboratory Investigations

These investigations may be divided into two major categories, namely:

1. **To confirm iron deficiency.**
2. **To determine the cause of iron deficiency (Table 9.7).**

Treatment of Plummer–Vinson syndrome: Administration of iron. Severe obstruction by the web may require dilatation. Regular upper GI endoscopy may be required for the early detection of cancers.

To confirm iron deficiency	*To determine the cause of iron deficiency*
Hemoglobin and hematocrit (PCV): Decreased	**Stool:** Examine for occult blood and hookworm infestation
Red cell indices: **MCV:** <80 fL; **MCH:** <25 pg; **MCHC:** <27 g/dL. **RDW: Increased,** >15%. Earliest sign of iron deficiency	
Peripheral smear: Microcytic hypochromic RBCs. Severe anemia—tear drop cells, target cells and pencil/cigar-shaped cells with anisocytosis and poikilocytosis with reactive thrombocytosis in a few cases **(Fig. 9.11)**	**Endoscopy:** This includes upper gastrointestinal endoscopy, sigmoidoscopy, and colonoscopy
Reticulocyte count: Low for degree of anemia	
Bone marrow: Moderate erythroid hyperplasia and micronormoblastic maturation	**Urine:** Examine for bleeding and for parasites such as schistosomiasis
Absence of bone marrow iron: "Gold standard" test, demonstrated by negative Prussian blue reaction	
Hepcidin: Decreased. Hepcidin regulates iron concentrations and tissue iron distribution	Investigations for malabsorption
A response to a therapeutic trial of iron administration may be helpful in confirming the diagnosis of iron deficiency anemia	

TABLE 9.7: Serum iron profile in IDA.

	Normal range	*Value in IDA*	*Observation*
Serum ferritin	15–300 µg/L	<15 µg/L	↓
Serum iron	50–150 µg/dL	10–15 µg/dL	↓
Serum transferrin saturation	30–40%	<15%	↓
Total iron-binding capacity (TIBC)	310–340 µg/dL	350–450 µg/dL	↑
Serum transferrin receptor (TFR)	0.57–2.8 µg/L	3.5–7.1 µg/L	↑
Red cell protoporphyrin	30–50 µg/dL	>200 µg/dL	↑

Soluble transferrin receptor (sTfR) and sTfR-ferritin index—reflect overall erythropoiesis, which is increased in iron deficiency. sTfR-ferritin index (sTfR ÷ log[ferritin]).

The sTfR reflects erythropoiesis, while the ferritin reflects the tissue iron stores; thus, a high sTfR-ferritin index (above 2–3) is a sign of iron deficiency due to increased erythropoietic drive and low iron stores. In anemia of chronic disease/anemia of inflammation, sTfR-ferritin index <1.

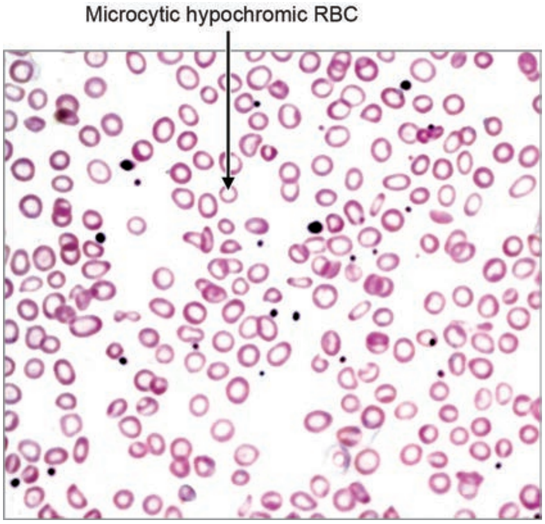

FIG. 9.11: Peripheral blood smear showing microcytic hypochromic red blood cells.

Differential Diagnosis

The microcytic hypochromic anemia does not necessarily mean only iron deficiency. The various causes of microcytic hypochromic anemia are listed in **Box 9.1**.

Complications of severe iron deficiency anemia are listed in **Box 9.2**.

Box 9.1: Differential diagnosis of microcytic hypochromic blood picture.

- Iron deficiency
- Thalassemia: It is an inherited defect in globin chain synthesis. It can be differentiated from iron deficiency by serum iron values, normal or increased serum iron levels, and transferrin saturation. The red blood cell distribution width (RDW) index is generally normal or reduced in beta thalassemia trait and elevated in iron deficiency
- Anemia of chronic disease
- Sideroblastic anemia
- Drugs/toxins that reduce heme synthesis (Lead, isoniazid, pyrazinamide, sirolimus)

Box 9.2: Complications of severe iron deficiency anemia.

- During pregnancy: Poor pregnancy outcomes such as premature births and low birth weight babies
- Heart failure
- Delayed growth and development in infants and children
- Increased susceptibility to infections
- Exacerbates cardiorespiratory problems, especially in the elderly

Q. IM9.13 **Prescribe replacement therapy with iron.**

Q. Write a short note on (1) iron therapy and (2) parenteral iron therapy.

Management

Treatment can be divided into: Treatment of underlying cause for iron deficiency. The correct management of iron deficiency is to identify and treat the underlying cause for deficiency.

Oral iron therapy

Most patients can be treated with oral iron preparations.

- **Iron preparations and dose:** Oral iron dose is 6 mg/kg/day. Commonly used and best are ferrous sulfate (200 mg three times daily, a total of 180 mg ferrous iron), ferrous gluconate (300 mg twice daily, only 70 mg ferrous iron), ferrous fumarate (325 mg two or three times daily), and others.
- *Alternate-day dosing appears to result in equivalent or better iron absorption than daily dosing, usually with fewer adverse effects.*
- **Side effects:** Few patients may develop metallic taste, nausea, dyspepsia, constipation, black tarry stools, or diarrhea. These can be reduced by taking iron tablets with food or reducing the dose or by using preparation with less iron (e.g., ferrous gluconate) or a controlled-release preparation or a liquid preparation.
- **Duration of oral iron therapy:**
  - Iron should be given to correct the Hb level to normal range and usually occurs within 4–6 weeks. If it does not occur, it may be due to failure of response to therapy.

  - Once the hemoglobin returns to normal, oral iron therapy should be continued to replace the iron stores. This may take 6 months to 1 year.
  - Patients having iron deficiency due to malabsorption, deficient intake, continuing blood loss, etc., may require long-term iron supplements at a minimum dose.
- **Response to oral iron therapy:** The response appears within 7–10 days of treatment with iron in the form of an increased reticulocyte count (usually not exceeding 10%, normal <2.5%).
- **Causes of failure to respond to oral iron therapy:** It may be due to one or more of the following reasons:
  - **Failure to take the iron tables:** Patients taking iron preparations have gray- or black-colored stools.
  - Continuing hemorrhage/blood loss.
  - **Incorrect/wrong diagnosis:** For example, thalassemia trait.
  - **Ingestion of drugs which reduce iron absorption:** Certain drugs if taken along with oral iron (e.g., H_2-receptor blockers, proton-pump inhibitors, antacids, tetracyclines) may interfere with iron absorption.
  - Severe malabsorption

Parenteral iron therapy

Parenteral iron therapy should be given only after the definite diagnosis of iron deficiency; otherwise it may lead to iron overload and its consequences. Iron stores are replaced much faster with parenteral iron than with oral iron, but the hematological response is not quick.

Indications of parenteral iron therapy:

- Intolerant to oral iron preparation.
- Severe malabsorption.
- Primary blood loss is uncontrollable: When the rate of iron (blood) loss exceeds the rate of its absorption.
- Chronic GI tract disease (e.g., inflammatory bowel disease) which may worsen with oral iron.

Calculation of total iron dose required.

Iron dose in mg = Body weight (kg) × 2.3 × (normal Hb—patient's hemoglobin, g/dL) + 500 or 1,000 mg (to provide body iron stores).

Route of administration: Parenteral iron can be given by slow intravenous infusion or by intramuscular injection.

Types of parenteral iron preparations: These include iron-sorbitol, iron-dextran (imferon), and preparations with much lower rates of adverse effects such as iron sucrose or sodium ferric gluconate, ferric carboxymaltose, and iron isomaltoside.

Iron-sorbitol

- It is administered only intramuscularly and never by the intravenous route.
- Dose is 1.5 mg of iron/kg body weight daily, to a dose not exceeding 2.5 g.

Iron-dextran (Imferon)

Low-molecular-weight iron dextran is most commonly used. It may be given either intramuscularly or intravenously (more ideal). Test dose is required before administration to prevent anaphylaxis.

- **Intramuscular:** Dose is 100 mg daily till the total required dose is administered or to a maximum of 2 kg. It should be given deep intramuscularly into the buttocks using a "Z-track technique."
- **Slow intravenous infusion:** Total dose intravenous infusion is rarely required. If a large dose is to be given (>100 mg), it should be diluted in 5% dextrose in water or 0.9% NaCl solution and infused slowly.

Iron-sucrose

- It has lesser adverse effects and is considered to be the safe intravenous iron preparation.
- It is given as a single dose of 100–200 mg as an intravenous injection or up to 500 mg infused over a period of 3 hours.

Sodium ferric gluconate

- It is the preferred form of parenteral iron owing to the low incidence of adverse reactions.
- It is administered intravenously at a dose of 125 mg over 10 minutes.

Ferric carboxymaltose: A novel iron complex that consists of a ferric hydroxide core stabilized by a carbohydrate shell allows for controlled delivery of iron to target tissues. Administered intravenously, it is effective in the treatment of iron-deficiency anemia, delivering a replenishment dose of up to 1,000 mg of iron during a minimum administration time of ≤15 minutes with least reactions.

Ferumoxytol: It is a superparamagnetic iron oxide nanoparticle coated with a low-molecular-weight (LMW) semisynthetic carbohydrate. It can be given in doses of 17 mL (equivalent to 510 mg of elemental iron).

Iron isomaltoside/ferric derisomaltose can be administered in a single infusion, at a dose of 20 mg/kg, over 15 minutes.

Side effects/toxicity of parenteral iron preparations

- Pain and swelling at the site of injection/infusion
- Anaphylactic reactions: Fever, generalized urticarial rash, lymphadenopathy, splenomegaly, and arthralgias
- Hemochromatosis

Red cell transfusion

- **Indication:** It is reserved for patients who have symptoms of anemia, cardiovascular instability, continued and excessive loss of blood loss from any site, and require immediate intervention.
- Transfusions correct the anemia acutely as well as transfused red cells provide a source of iron for reutilization.

MACROCYTIC ANEMIA

Q. PA15.1 Describe the metabolism of vitamin B_{12} and the etiology and pathogenesis of B_{12} deficiency.

Vitamin B_{12} and folic acid are closely related, and both are essential for normal DNA synthesis and nuclear maturation.

Vitamin B_{12} Metabolism

- Vitamin B_{12} is present only in animal proteins and dairy products and not present in vegetables. Therefore, strict vegetarians do not get an adequate quantity of vitamin B_{12}.
- A balanced diet (not rigid vegetarian!) contains significantly large amounts of vitamin B_{12} which accumulates in the body (liver) and is enough for several (about 3 years). Hence, if there is any dietary deficiency or malabsorption of vitamin B_{12}, its clinical manifestations appear only after about 2–4 years.
- Normal daily requirement is about **2–3** µg.

Absorption, Transport, and Storage (Fig. 9.12)

- Vitamin B_{12} in food is usually in coenzyme form (as deoxyadenosylcobalamin and methylcobalamin) and bound to binding proteins in the diet.
- In the stomach, peptic digestion at low pH is required for release of vitamin B_{12} from binding protein in the food. The released vitamin B_{12} binds with salivary protein called **haptocorrin**, which is secreted in salivary juice.
- These haptocorrin-B_{12} complexes leave the stomach along with an unbound special protein called **intrinsic factor** (IF), which is produced by gastric (fundus and cardia) parietal (oxyntic) cells.
- As haptocorrin-B_{12} complexes pass into the second part of the duodenum, pancreatic proteases release vitamin B_{12} from haptocorrin. Vitamin B_{12} then associates with the intrinsic factor and forms the IF-B_{12} complex.
- This stable IF-vitamin B_{12} complex is transported to the ileum, where it is endocytosed by ileal enterocytes. These ileal enterocytes express a receptor on their surfaces for the intrinsic factor. These receptors are called **cubilin**.
- In the ileal epithelium, vitamin B_{12} combines with a major carrier protein, **transcobalamin II**, and is actively transported into the mucosal cells and then into the blood.
- Transcobalamin II-vitamin B_{12} complex delivers vitamin B_{12} to the liver and other cells of the body, particularly rapidly proliferating cells in the bone marrow and mucosal lining of the gastrointestinal tract.

FIG. 9.12: Mechanism of vitamin B_{12} absorption.

Role of Vitamin B_{12}

Vitamin B_{12} is essential for:

- Normal hematopoiesis
- Maintenance of normal integrity of the nervous system

Vitamin B_{12} is indirectly required for DNA synthesis in various metabolic steps and its deficiency impairs DNA synthesis. There are two biologically active forms of cobalamin in the body; both act as coenzymes, namely: (1) methylcobalamin and (2) adenosylcobalamin.

1. Methylcobalamin is the main form of vitamin B_{12} in plasma and is an essential coenzyme for conversion of homocysteine to methionine and formation of tetrahydrofolate (THF) from methyl THF **(Fig. 9.13)**. During the former reaction, vitamin B_{12} loses its methyl group and this is replaced from methyl THF, the principal form of folic acid in plasma. Tetrahydrofolate is essential for the generation of a precursor of DNA known as deoxythymidine monophosphate (D TMP).

   In vitamin B_{12} deficiency, the main cause of impaired DNA synthesis is that methyl THF is not converted into THF. Methyl THF accumulates in the cell and is known as "**Methyl THF trap**". Lack of folic acid is the next cause of anemia in vitamin B_{12} deficiency, as the anemia invariably improves with folic acid administration.
2. Deoxyadenosylcobalamin form of vitamin B_{12} is a coenzyme required for conversion of methylmalonyl CoA to succinylmalonyl CoA **(Fig. 9.14)**. Deficiency of vitamin B_{12} causes increased levels of methylmalonic acid in plasma and urine. This results in the formation of abnormal fatty acids which get incorporated into neuronal lipids. Consequently, this predisposes to myelin breakdown and is probably responsible for neurologic complications of vitamin B_{12} deficiency.

Folic Acid Metabolism

Q. Write a short essay/note on folic acid.

- **Daily requirement:** 50–200 mg
- **Source:** Green vegetables, yeast, legumes, fruits, and animal proteins are the richest sources. The folic acid in these foods is largely in the form of polyglutamates. Polyglutamates are sensitive to heat (thermolabile), boiling, steaming or frying, which destroy most of the folic acid (destroyed by cooking). Intestinal conjugates split the polyglutamates into monoglutamates.
- **Site of absorption:** Proximal jejunum. During intestinal absorption, they are modified to 5-methyltetrahydrofolate, the normal transport form of folic acid (FA).
- **Storage:** Folate is mainly stored in the liver and is enough for about 3 months and hence the manifestations of folate deficiency appear after about 3 months.

Role of Folic Acid

The active form of folic acid is tetrahydrofolate (THF) which is the biologic "middleman" involved in metabolic processes which synthesize DNA. The various reactions in which folic acid plays a main role are:

- Purine (required for DNA and RNA) synthesis
- Conversion of homocysteine to methionine, a reaction also requiring vitamin B_{12}
- Deoxythymidylate monophosphate synthesis: 5,10-methylene THF polyglutamate is required for conversion of deoxyuridine monophosphate (dUMP) to deoxythymidine monophosphate (dTMP) and DNA, a rate-limiting step in pyrimidine synthesis.

Folic acid is associated with metabolism of histidine: Histidine is metabolized to formiminoglutamic acid (FIGLU) which combines with THF to form glutamic acid **(Fig. 9.15)**. In FA deficiency, this reaction cannot take place and therefore FIGLU accumulates and is excreted as such in urine. This is used as a test to measure folic acid deficiency.

Manifestations of Megaloblastic Anemia

Q. Discuss the causes, clinical features/manifestations, and management of vitamin B_{12} deficiency/megaloblastic anemia.

Q. Discuss the causes, clinical features/manifestations, and management of folate deficiency.

Megaloblastic anemias are a group of disorders characterized by **defective**/impaired **DNA synthesis** and **distinct megaloblasts in the bone marrow** and **macrocytes in the peripheral blood**. Megaloblastic anemias are common among anemias due to impaired red cell production. They are usually caused **due to deficiency of either cobalamin (vitamin B_{12}) or folate (folic acid)** but may occur because of genetic or acquired abnormalities that affect the metabolism of these vitamins.

Etiology of Megaloblastic Anemia (Table 9.8)

TABLE 9.8: Etiology of megaloblastic anemia.

Vitamin B_{12} deficiency	***Folic acid deficiency***
Decreased intake: Inadequate diet, "pure vegetarians"	**Decreased intake:** Inadequate diet—alcoholism, malnutrition
Increased demand: Pregnancy, hyperthyroidism, disseminated cancer	**Increased loss:** Hemodialysis
Impaired absorption ➢ Gastric: Deficiency of gastric acid or pepsin or intrinsic factor – Pernicious anemia – Postgastrectomy – Drugs: Prolonged use of H_2-receptor blockers and proton-pump inhibitors ➢ Intestinal – Loss of absorptive surface ◆ Malabsorption syndromes ◆ Diffuse intestinal disease—lymphoma, systemic sclerosis ◆ Ileal resection, Crohn disease – Competition for vitamin B_{12}—bacterial overgrowth in blind loops and diverticula of bowel, ***Diphyllobothrium latum***	**Impaired absorption** ➢ Malabsorption states: Nontropical and tropical sprue, celiac disease ➢ Diffuse infiltrative diseases of the small intestine (e.g., lymphoma) ➢ Drugs: Anticonvulsant phenytoin, oral contraceptives, metformin, cholestyramine
	Increased demand: Pregnancy, lactation, infancy, disseminated cancer, markedly increased hematopoiesis (hemolytic anemias), chronic exfoliative skin disease, chronic inflammatory and infectious diseases
Abnormal cobalamin transport: Transcobalamin II deficiency	**Impaired utilization**: Folic acid antagonists (antifolate drugs), such as methotrexate, trimethoprim, pyrimethamine, pentamidine, 5-fluorouracil, hydroxyurea
Others—Antifolate drugs: e.g., methotrexate; Independent of either cobalamin or folate deficiency	

Pathogenesis (Mechanism) of Megaloblastic Anemia

- Megaloblastic anemias are commonly due to deficiency of **vitamin B_{12} (cobalamin) or folic acid**, which are coenzymes required for the synthesis of one of the four bases found in DNA, namely thymidine.
- Deficiency of cobalamin or folate results in failure of DNA synthesis and delayed/arrested nuclear maturation. Synthesis of RNA and protein is normal resulting in normal cytoplasmic maturation. Thus, the **nuclear maturation lags behind the cytoplasmic maturation** producing nucleocytoplasmic asynchrony. This results in abnormal cell proliferation that affects rapidly dividing cells in the bone marrow (erythroid, myeloid, and megakaryocyte series).
- Impaired DNA synthesis causes delay in cell division and increases time between divisions and size of the cells become large and are called as "megaloblasts." The **megaloblasts** have an open, stippled, and lacy chromatin (characteristically called sieve like chromatin). The megaloblastic changes are most prominent in the early nucleated red cell precursors.
- Erythroid precursor cells show a reduced number of mitoses, and synthesis of hemoglobin is unimpaired. The mature RBCs derived from these megaloblasts are large (**macrocytes**) and **oval** but well hemoglobinized.
- In the bone marrow, a large number of megaloblastic precursors do not mature enough to be released into the blood and are destroyed in the bone marrow (ineffective erythropoiesis). There is also mild hemolysis of red cells in the peripheral blood. This releases large amounts of **lactate dehydrogenase (LDH)** resulting in **raised** levels in the blood.
- In the bone marrow, abnormal proliferation affects myeloid series producing giant metamyelocytes and the megakaryocyte series resulting in dysplastic megakaryocytes.
- All rapidly dividing cells of the body (including skin, GI tract, bone marrow) exhibit megaloblastic changes, and anemia is only a manifestation of a more generalized defect in DNA synthesis.

Pathogenesis of Neurological Changes in Vitamin B_{12} Deficiency

Two mechanisms are responsible for neurologic changes seen in vitamin B_{12} deficiency. Deficiency of vitamin B_{12} causes:

- **Impairment in the conversion of homocysteine to methionine:** Methionine is required for the production of choline and choline-containing phospholipids. These are needed by the neuronal cells.

- **Lack of adenosylcobalamin:** It is a vitamin B_{12}–containing cofactor required for the conversion of methylmalonyl CoA to succinyl CoA. Lack of this cofactor results in increased levels of methylmalonyl CoA and its precursor, propionyl CoA. This causes production of nonphysiologic fatty acids and is incorporated into neuronal lipids.

Pernicious Anemia

Q. Discuss the etiology of Addisonian pernicious anemia.

Pernicious anemia (PA) is a chronic autoimmune disorder characterized by atrophic gastritis with loss of parietal cells in the gastric mucosa which causes failure of production of intrinsic factor. Absence of intrinsic factor results in failure of absorption of dietary vitamin B_{12} and deficiency which eventually produces megaloblastic macrocytic anemia.

- **Age and gender:** PA is a disease of older age and generally presents in the fifth to eighth decades of life. Females are more involved than males (F:M is 1.5:1).

Etiology

Pernicious anemia is an autoimmune disease causing destruction and permanent atrophy of gastric mucous membrane. The evidences for autoimmune etiology are as follows:

- It is associated with other autoimmune diseases such as Graves' disease, Hashimoto's thyroiditis, vitiligo, and Addison's disease.
- Microscopically, the stomach shows **chronic atrophic gastritis** with damage to gastric parietal cells.
- Response to steroids is seen.
- There is presence of autoantibodies in most of the patients. **Two major types** of autoantibodies are found:
  1. **Anti-intrinsic factor (IF) antibody:**
     - Type I (blocking) antibody: This blocks the binding of vitamin B_{12} to IF and is present in 50–75% of the cases and can be detected in both plasma and gastric juice.
     - Type II (binding) antibody: It attaches to the IF–vitamin B_{12} complex and prevents their binding to receptors in the ileal mucosa. They are present in about 40% of patients.
  2. **Parietal cell (type III) antibody:** It is directed against α and β subunits of the gastric proton pump (H^+, K^+-ATPase) in parietal cells but is neither specific for PA nor other autoimmune disorders. They are found in 90% of patients with PA as well as in older patients with chronic nonspecific gastritis.

Role of *Helicobacter pylori:* *H. pylori* gastritis may play a role in PA. There is a **higher incidence of gastric carcinoma** in patients with PA. The incidence is higher in patients with blood group A.

Clinical Features of Macrocytic Anemias (Fig. 9.16)

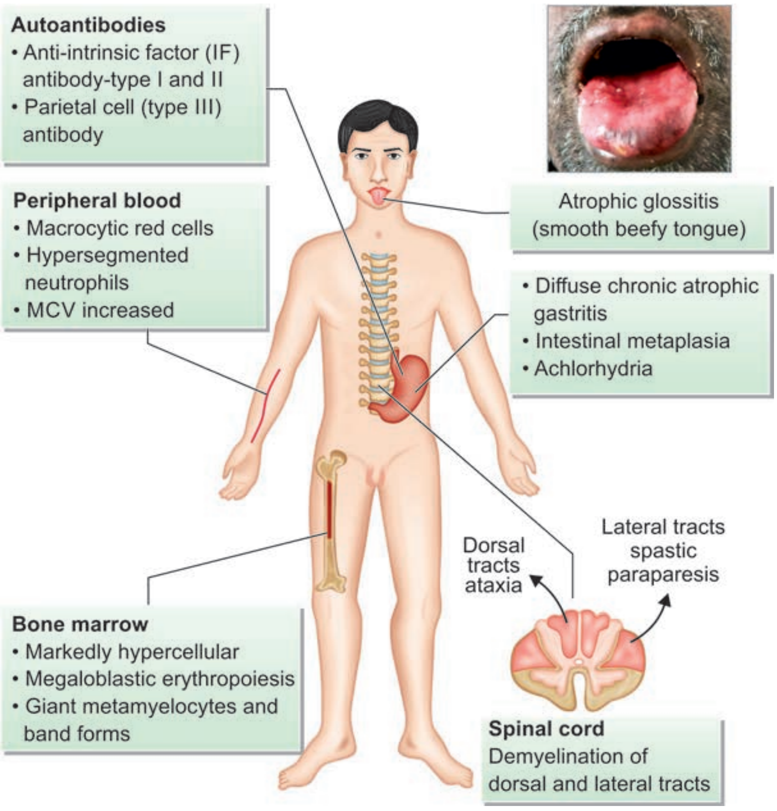
Q. Discuss clinical manifestations of vitamin B_{12} deficiency/folate deficiency/pernicious anemia.

Onset

The onset is insidious in origin and progresses slowly unless halted by therapy.

Clinical features related to vitamin B_{12} deficiency:

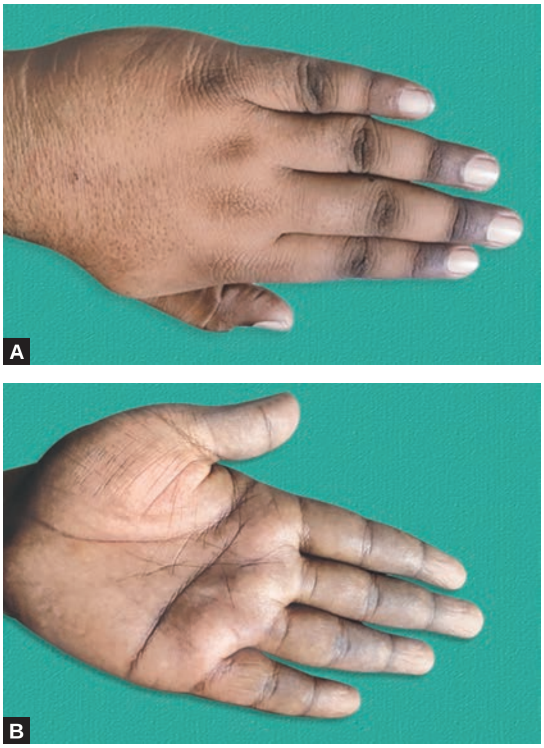
- Classic triad: Weakness, sore throat, and paresthesias
- Tongue: Painful **red "beefy"** tongue due to glossitis and atrophy of papillae **(Fig. 9.16)**. The patient complains of loss of taste and appetite.
- Patients may have a lemon-yellow color due to combination of pallor and mild jaundice caused by excess breakdown of hemoglobin.



Autoantibodies
• Anti-intrinsic factor (IF) antibody-type I and II
• Parietal cell (type III) antibody
Atrophic glossitis (smooth beefy tongue)
Peripheral blood
• Macrocytic red cells
• Hypersegmented neutrophils
• MCV increased
• Diffuse chronic atrophic gastritis
• Intestinal metaplasia
• Achlorhydria
Dorsal tracts ataxia
Lateral tracts spastic paraparesis
Bone marrow
• Markedly hypercellular
• Megaloblastic erythropoiesis
• Giant metamyelocytes and band forms
Spinal cord
Demyelination of dorsal and lateral tracts

FIG. 9.16: Clinical features and laboratory findings in pernicious anemia.

Pigmentation: Pigmentation of knuckles and creases is common **(Figs. 9.17A and B)**. The generally accepted mechanism of pigmentation is an increase in the melanin synthesis. The other hypotheses proposed are: (1) Deficiency of vitamin B_{12} decreases the level of reduced glutathione, which activates tyrosinase and thus leads to transfer to melanosomes. (2) Defect in the melanin transfer between melanocytes and keratinocytes, resulting in pigmentary incontinence.



FIGS. 9.17A AND B: (A) Pigmentation of knuckles; (B) Pigmentation of creases.

Neurological Features

Q. Write a short essay/note on neurological complications of pernicious anemia/megaloblastic anemia.

- **Peripheral nerves-peripheral neuropathy:** Glove and stocking distribution of numbness or paresthesia. This tingling begins in the tips of toes and progresses proximally and is bilateral and symmetric. It is characterized by loss of ankle reflexes.
- **Spinal cord:** Subacute combined degeneration of the cord
  - *Posterior columns:* Impaired/diminished vibration and position sensation
  - *Corticospinal tracts:* Upper motor neuron signs—ataxic, uncoordinated gait. Bilateral extensor plantar with absent ankle jerks
- **Cerebrum:** Depression and loss of memory (dementia), optic atrophy
- A positive Romberg sign and Lhermitte sign may be elicited.
- *Folate deficiency in adults does not give rise to significant neurologic findings.*
- Prematurely gray-haired
- Atherosclerosis: Serum homocysteine level is raised and is a risk factor for **atherosclerosis and thrombosis** (myocardial infarction, stroke).

Pernicious anemia: Symptoms are same as those of vitamin B_{12} deficiency. In addition:

- **Hypochlorhydria:** Atrophic gastritis causes decreased secretion of hydrochloric acid and IF. The symptoms include dyspepsia, postprandial fullness, and early satiety.

Clinical Features Related to Folate Deficiency

They are similar to those of vitamin B_{12} deficiency except for neurological features.

Diagnosis/Laboratory Findings of Megaloblastic Anemia

Q. PA15.2 Describe the laboratory investigations of macrocytic anemia

Q. Discuss the diagnosis of anemias due to vitamin B_{12} deficiency.

Blood findings in vitamin B_{12} (including pernicious anemia) and/or folic acid deficiency are similar.

Common Findings

Peripheral blood

Q. Describe the peripheral blood and bone marrow picture in megaloblastic anemia.

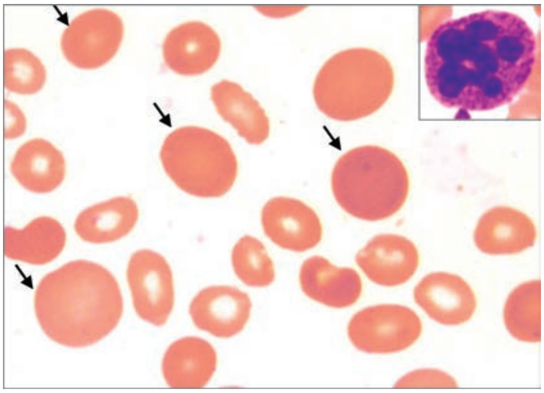


FIG. 9.18: Peripheral blood smear showing macro-ovalocytes (short arrows) and hypersegmented neutrophil (inset).

- **Hemoglobin and hematocrit (PCV):** Reduced
- **Red cell indices: MCV raised** above 100 fL (normal 82–98 fL)
- RBC, WBC, and platelet count: All are reduced.
- **Peripheral smear (Fig. 9.18): Pancytopenia** (decreased RBCs, WBCs, and platelets)
  - **RBCs:**
    - Macrocytic and oval (egg-shaped macro-ovalocytes) and are diagnostic
    - Marked variation in the size and shape of red cells (anisopoikilocytosis)

        - Earliest change in RBCs is mild anisocytosis
        - Evidence of dyserythropoiesis: Basophilic stippling, Cabot ring, and Howell–Jolly bodies
    - **WBCs:**
        - Decreased WBC count (leukopenia)
        - **Hypersegmented neutrophils** (more than five nuclear lobes): First and specific morphological sign of megaloblastic anemia. These neutrophils are also larger than normal. Typically more than 5% of the neutrophils have five lobes.
    - **Platelets: Decreased**
- **Reticulocyte count:** Normal or low. Reticulocytosis occurs in response to very small doses of parenteral vitamin B_{12}.

Bone marrow

- **Markedly hypercellular with erythroid hyperplasia (M:E ratio = 1:1 or lower)**
- **Megaloblastic type of erythroid maturation:** Megaloblasts with sieve like chromatin. Though these changes are most clearly seen in later stages of erythroblasts, there is a predominance of more immature forms like basophilic erythroblasts **signifying maturation arrest**.
- Granulocytic precursors display nuclear-cytoplasmic asynchrony in the form of **giant metamyelocytes and band forms**.
- **Megakaryopoiesis:** Normal or increased in number
- **Bone marrow iron:** Moderately increased

Biochemical tests (common for both vitamin B_{12} and folic acid deficiency)

- **Deoxyuridine suppression test:** It is a sensitive measure of deficiency of 5, 10-methylene THF, which occurs in both folic acid and vitamin B_{12} deficiency.
- Serum homocysteine levels are raised.
- Serum bilirubin: Indirect bilirubin is mildly increased due to increased breakdown of red cells in bone marrow and produces mild jaundice.
- Serum iron and ferritin are raised and iron-binding capacity is reduced.
- Plasma lactate dehydrogenase (LDH) is markedly increased.
- Serum vitamin B_{12}/folate is decreased.

Diagnostic/Specific Tests for Vitamin B_{12} Deficiency

- Serum vitamin B_{12} levels: Reduced **and levels are very low** (<200 pg/μL).
- Serum methylmalonic acid (MMA) and homocysteine levels **(Table 9.9)**: Raised.
- Urinary excretion of methylmalonic acid: Raised.
- **Schilling test** (refer below) for vitamin B_{12} absorption, which was discontinued in 2003, once provided invaluable information on the locus and mechanism of cobalamin malabsorption.

Diagnostic/Specific Tests for Folic Acid Deficiency

- **RBC folic acid levels: Reduced**
- **FIGLU in urine: Excessively excreted.**

TABLE 9.9: Test results on metabolites: Serum methylmalonic acid and total homocysteine in megaloblastic anemia.

Methylmalonic acid (Normal: 70–270 nM)	***Total homocysteine (Normal: 5–14 μM)***	***Diagnosis***
Increased	Increased	Vitamin B_{12} deficiency confirmed; folate deficiency is still possible (i.e., combined vitamin B_{12} plus folate deficiency possible)
Normal	Increased	Folate deficiency is likely; <5% may have vitamin B_{12} deficiency
Normal	Normal	Vitamin B_{12} and folate deficiencies are excluded

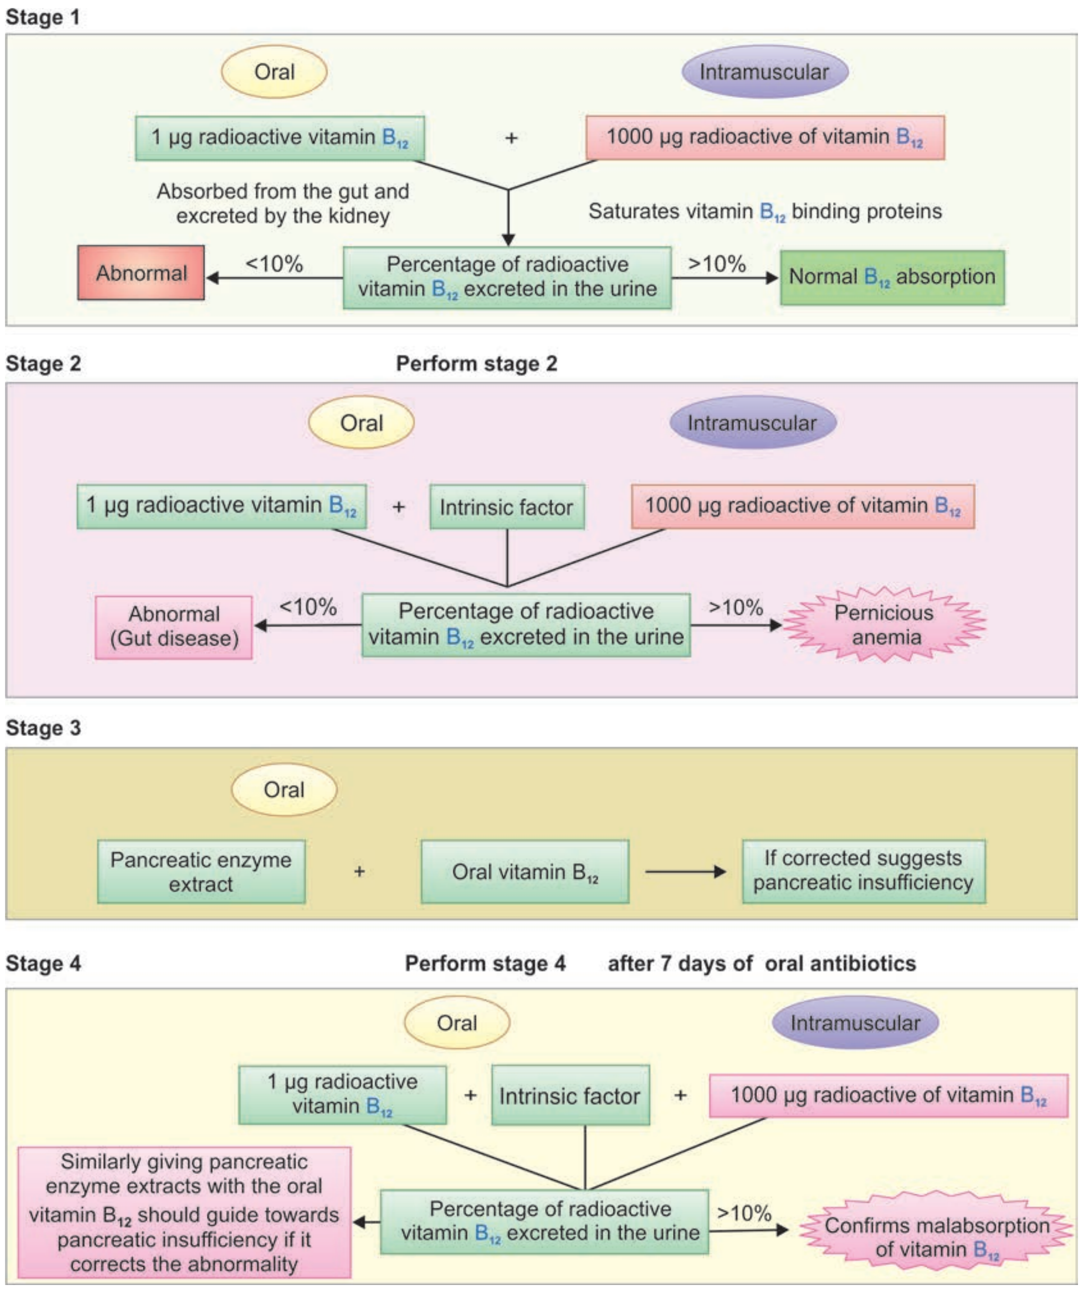
Determining the Cause of the Vitamin (Folate/Vitamin B_{12}) Deficiency

- The cause of folate deficiency is usually determined from the history, physical examination, and clinical features.
- In adults, the cause of vitamin B_{12} deficiency is either due to vitamin B_{12} malabsorption or dietary deficiency of vitamin B_{12}. To determine the basis for malabsorption, one needs additional diagnostic tests (e.g., intestinal biopsy, examination of stool for malabsorption, or *Diphyllobothrium latum* infestation) and requires specific therapy (e.g., gluten-free diet, folate, antibiotics, antihelminthics). A detailed dietary history or past medical history (e.g., gastroduodenal disease, pancreatic insufficiency, impaired bowel motility, or other autoimmune diseases) and physical examination can provide additional clues for other causes.

Schilling Test for Vitamin B_{12} Absorption (Fig. 9.19)

Q. Write a short essay on the Schilling test/vitamin B_{12} absorption test.

Use: Schilling test helps in distinguishing megaloblastic anemia due to IF deficiency (pernicious anemia) from other causes of vitamin B_{12} deficiency. It is diagnostic of PA, is of historical interest, and is now very infrequently performed.



Stage 1
Oral
Intramuscular
1 µg radioactive vitamin B12
+
1000 µg radioactive of vitamin B12
Absorbed from the gut and excreted by the kidney
Saturates vitamin B12 binding proteins
Abnormal
<10%
Percentage of radioactive vitamin B12 excreted in the urine
>10%
Normal B12 absorption
Stage 2
Perform stage 2
Oral
Intramuscular
1 µg radioactive vitamin B12
+
Intrinsic factor
1000 µg radioactive of vitamin B12
Abnormal (Gut disease)
<10%
Percentage of radioactive vitamin B12 excreted in the urine
>10%
Pernicious anemia
Stage 3
Oral
Pancreatic enzyme extract
+
Oral vitamin B12
If corrected suggests pancreatic insufficiency
Stage 4
Perform stage 4 after 7 days of oral antibiotics
Oral
Intramuscular
1 µg radioactive vitamin B12
+
Intrinsic factor
+
1000 µg radioactive of vitamin B12
Similarly giving pancreatic enzyme extracts with the oral vitamin B12 should guide towards pancreatic insufficiency if it corrects the abnormality
Percentage of radioactive vitamin B12 excreted in the urine
>10%
Confirms malabsorption of vitamin B12

FIG. 9.19: Stages of Schilling test.

Method and interpretation

Radioactive vitamin B_{12} (1 µg) is given orally to a fasting patient. This is followed by nonradioactive 1,000 µg of vitamin B_{12} intramuscularly. The injected vitamin B_{12} saturates vitamin B_{12}-binding proteins and flushes out the ingested radioactive vitamin B_{12} which will be excreted in urine. The urine is collected for 24 hours.

- **Stage 1:**
  - Normal persons excrete more than 10% of oral radioactive dose in 24-hour urine.
  - Patients with pernicious anemia excrete less than 5% of the oral dose.
- **Stage 2:** If the test is abnormal
  - The test is repeated with addition of oral intrinsic factor to radioactive vitamin B_{12}.
  - If the urinary excretion is now normal, the diagnosis is intrinsic factor deficiency due to either pernicious anemia or gastrectomy.

- **Stage 3:** Giving pancreatic enzyme extracts with the oral vitamin B_{12} should guide toward pancreatic insufficiency if it corrects the abnormality.
- **Stage 4:**
  - If the excretion is still abnormal, the lesion must be in the terminal ileum or there may be bacterial overgrowth. The bacterial overgrowth may be corrected by a 7-day course of oral tetracycline/antibiotics. The test is repeated after a course of oral tetracycline.
  - If the excretion returns to normal, it confirms that malabsorption of vitamin B_{12} is due to bacterial overgrowth in the intestine.

Specific diagnostic tests for pernicious anemia

- Serological tests
  - Anti-intrinsic factor antibodies in serum (in 70% of patients; highly specific for pernicious anemia)
  - Antiparietal cell antibodies (in 85–90%; less specific compared to anti-intrinsic antibodies)
- Achlorhydria with histamine stimulation
- Severe deficiency of intrinsic factor.

Other Nonspecific Tests

- Serum gastrin is raised.
- Pepsinogen I is decreased.
- Gastric biopsy shows mucosal atrophy and inflammatory infiltrate of lymphocytes and plasma cells.

Q. IM9.13 Prescribe replacement therapy with B_{12}, and folate.

Q. Discuss the management of megaloblastic macrocytic anemias.

Q. Discuss the management of Addisonian pernicious anemia.

Management of Megaloblastic Macrocytic Anemia

Treatment consists of treating the underlying cause, whenever possible.

Specific therapy

Treatment of underlying cause of vitamin B_{12} or folate deficiency.

Vitamin B_{12}/Cobalamin deficiency

Vitamin B_{12} therapy (cyanocobalamin, hydroxocobalamin, or methylcobalamin may be used)

- **Dosage:**
  - **Initial dose:** It is treated with six intramuscular injections of hydroxycobalamin 1,000 µg given at 3–7-day intervals.
  - **Maintenance dose:** Maintenance dose of 1,000 µg to be given intramuscularly every 3 months for the rest of the patient's life. Methylcobalamin, a metabolically active form of vitamin B_{12}, can also be used.
- *An aggressive scheme to replace vitamin B_{12} rapidly is 1 mg of intramuscular cyanocobalamin per day (week 1), 1 mg twice weekly (week 2), 1 mg/week for 4 weeks, and then 1 mg/month for life.*
- **Response:** Clinical improvement may occur within 48 hours (LDH and bilirubin will normalize) and a reticulocytosis peak by the 3–4th day after therapy and may be as high as 50%. Anemia will correct by 4–6 weeks. Improvement of the sensory polyneuropathy may take 6–12 months to correct, but longstanding spinal cord damage is irreversible. Hypokalemia may occur during the initial week of treatment as there is marked potassium uptake during production of new blood cells.
- **Dimorphic anemia:** If there is associated iron deficiency, ferrous sulfate 200 mg thrice daily orally should be started soon after the commencement of vitamin B_{12} therapy.

Folate deficiency

- **Dosage:** Oral dose of 5 mg folate (folic acid) daily for 3 weeks will treat acute deficiency and 5 mg once weekly is adequate maintenance therapy.
- Folinic acid is of value to bypass the block of dihydrofolate reductase by methotrexate and trimethoprim-sulfamethoxazole.
- Congenital folate malabsorption arising from inadequate folate transport across the gastrointestinal tract and blood-brain barrier responds to parenteral leucovorin in high doses.
- **Response** is same as seen after treatment of vitamin B_{12} deficiency.
- **Precaution:** Large doses of folic acid alone should not be given to treat megaloblastic anemia (such as pernicious anemia or other vitamin B_{12} deficiency anemias) unless the serum vitamin B_{12} level is known to be normal. If vitamin B_{12} deficiency is present, it should be corrected first; otherwise cobalamin neuropathy may be aggravated or precipitated despite a response of the anemia of cobalamin deficiency to folate therapy.
- **Prophylactic folic acid in pregnancy:** Prophylactic folic acid in the dose of 400 µg daily is recommended for all women planning a pregnancy to reduce the risk of fetal neural tube defects.

Supportive therapy

- Blood transfusions: Transfusion is usually not necessary and not advisable. It should be given in significantly symptomatic and severely anemic patients with angina or heart failure.
- Other measures: Treatment of infection and physiotherapy in nervous system involvement.

Follow-up

- Clinical and hematological examination should be carried out every 6 months.
- Pernicious anemia: Carcinoma of stomach and gastric carcinoids are more common in patients with pernicious anemia and early detection is important.

Causes of Macrocytosis

Q. Enumerate the causes of macrocytosis/macrocytic anemia.

Macrocytes are large red blood cells with a diameter of more than 9 µ and MCV of more than 95 fL. The macrocytic anemias can be divided into megaloblastic and nonmegaloblastic types, depending on the appearance of developing red cell precursors in the bone marrow.

Megaloblastic Macrocytic Anemia

It is characterized by raised MCV with macrocytosis on the peripheral blood and the presence of abnormal red precursors of the bone marrow known as megaloblasts. Causes of megaloblastic anemia include deficiency of vitamin B_{12}, folate or copper, and drugs that interfere with purine or pyrimidine metabolism. The peripheral blood smear shows macro-ovalocytes and hypersegmented neutrophils.

Nonmegaloblastic Macrocytic Anemia

It is characterized by a raised MCV with macrocytosis on the peripheral blood film with a normoblastic rather than a megaloblastic bone marrow. Common causes are listed in **Box 9.3**. These conditions are associated with normal levels of vitamin B_{12} and folate.

Box 9.3: Causes of nonmegaloblastic macrocytic anemia.

Abnormalities of DNA metabolism

Drugs

- Zidovudine
- Azathioprine or 6-mercaptopurine
- Capecitabine
- Cladribine
- Cytosine arabinoside
- Hydroxyurea
- Imatinib, sunitinib
- Methotrexate

Shift to immature or stressed red cells

- Reticulocytosis
- Action of erythropoietin—skip macrocytes, stress erythrocytosis
- Aplastic anemia/Fanconi anemia
- Pure red cell aplasia

Primary bone marrow disorders

- Myelodysplastic syndromes
- Congenital dyserythropoietic anemias
- Some sideroblastic anemias
- Large granular lymphocyte (LGL) leukemia

Lipid abnormalities

- Liver disease
- Hypothyroidism

Mechanism unknown

- Alcohol abuse
- Multiple myeloma

HEMOLYTIC ANEMIAS

Q. PA16.1 Define and classify hemolytic anemia. Discuss the clinical features, diagnosis, and management of hemolytic anemias.

Q. PA16.2 Describe the pathogenesis and clinical features and hematologic indices of hemolytic anemia.

Definition

Hemolytic anemias are defined as anemias that result due to increase in the rate of red cell destruction. The life span of red cells (normal life span is 90–120 days) is shortened.

Compensated Hemolytic Disease

Shortening of red cell survival may not always cause anemia as bone marrow can compensate by increased production of red cells by six to eight times.

Classification of Hemolytic Anemias (Table 9.10)

The hemolytic anemias are classified in a variety of ways.

1. **Location of hemolysis:** Depending upon the site of red cell destruction, it can be classified as **intravascular and extravascular** hemolytic disorders.
2. **Source of defect causing hemolysis:** Hemolysis may be due to a defect intrinsic to the red cell itself (**intracorpuscular defect)** or due to an abnormality outside the red cell **(extracorpuscular mechanism).**
3. **Mode of onset: Hereditary and acquired** disorders
4. **Clinical point of view: Acute or chronic**

TABLE 9.10: Classification and causes of hemolytic anemia.

Hereditary	*Acquired*
Defects in red cell membrane	**Immune hemolytic anemias**
Hereditary spherocytosis hereditary elliptocytosis Stomatocytosis Abetalipoproteinemia (Acanthocytosis)	**Autoimmune hemolytic anemias** **1. Due to warm antibodies** Idiopathic Secondary **2. Due to cold antibodies** Cold agglutinin disease Paroxysmal cold hemoglobinuria **3. Hemolytic disease of the newborn**
Red cell enzyme deficiencies	**Fragmentation syndromes**
Pyruvate kinase deficiency Hexokinase deficiency Glucose-6-phosphate dehydrogenase deficiency (G6PD)	Hemolytic uremic syndrome Thrombotic thrombocytopenic purpura Disseminated intravascular coagulation Prosthetic cardiac valves
Defects in globin synthesis—Hemoglobinopathies	**Miscellaneous**
Thalassemia—quantitative Sickle cell syndromes—qualitative Alpha thalassemia Unstable hemoglobin disease	Drugs—oxidant drugs (Primaquine, Dapsone) Chemical—naphthalene, nitrites and nitrates, oxidizing chemicals Thermal injury—burns **Paroxysmal nocturnal hemoglobinuria**

Clinical Features of Hemolytic Anemia

Symptoms/History	*Physical findings/Signs*
➢ Mild jaundice ➢ Symptoms due to anemia ➢ Urine color—appears normal (acholuric), turns dark on standing due to oxidation of urobilinogen to urobilin. Black urine (hemoglobinuria) seen in intravascular hemolysis (malaria, mismatched blood transfusion, G6PD deficiency) ➢ Infections ➢ Splenic pain: Enlargement or infarction of spleen ➢ Acute crisis: Due to sudden fall in hemoglobin—fever, joint pains, and abdominal pain ➢ Pigment gallstones: Chronic hemolysis ➢ Leg ulcers manifest in adult males: Hereditary spherocytosis and sickle cell anemia ➢ Family history: Congenital hemolytic anemias	➢ Anemia ➢ Mild jaundice ➢ Splenomegaly: Some cases of hemolytic anemia—thalassemia, hereditary spherocytosis ➢ Chronic leg ulcers: Sickle cell anemia ➢ Skeletal abnormalities: Expansion of bone marrow in some congenital hemolytic anemias due to increased erythropoiesis, manifests as enlargement of maxillary bones and frontal bossing and malocclusion of the teeth due to overgrowth of upper jaw (thalassemic facies) ➢ Signs of systemic disease: Predisposing to hemolysis ➢ Signs of cholelithiasis: Cholecystitis

Diagnosis of Hemolytic Anemias

Q. Write a short essay on laboratory investigations/features of hemolysis/hemolytic anemia.

Recognition of Hemolysis (Table 9.11 and Fig. 9.20)

Features of increased RBC production: As a compensatory mechanism to hemolysis, there is increased production of red cells.

- **Bone marrow** shows **compensatory erythroid hyperplasia.**
- **Peripheral smear** shows **increased reticulocytes** (reticulocytosis), nucleated red cells, and polychromasia. Other findings vary depending on the cause mentioned below.
- **Radiological changes:** Hair-on-end appearance in skull radiograph (thalassemia, sickle cell anemia) is seen.

Recognition of Cause of Hemolysis

- Common tests:
    - **Peripheral smear examination:** Red cell morphology provides a clue to the underlying hemolytic disorders such as: (1) spherocyte (hereditary spherocytosis, autoimmune hemolytic anemia), (2) sickle cell (sickle cell anemia), (3) target cell (thalassemia), (4) acanthocyte, (5) schistocyte (intravascular hemolysis-fragmented red cells, helmet cells, triangular cells), and (6) malarial parasite.

TABLE 9.11: Summary of laboratory features of hemolytic anemia.

1. Features/consequences of increased RBC destruction/breakdown

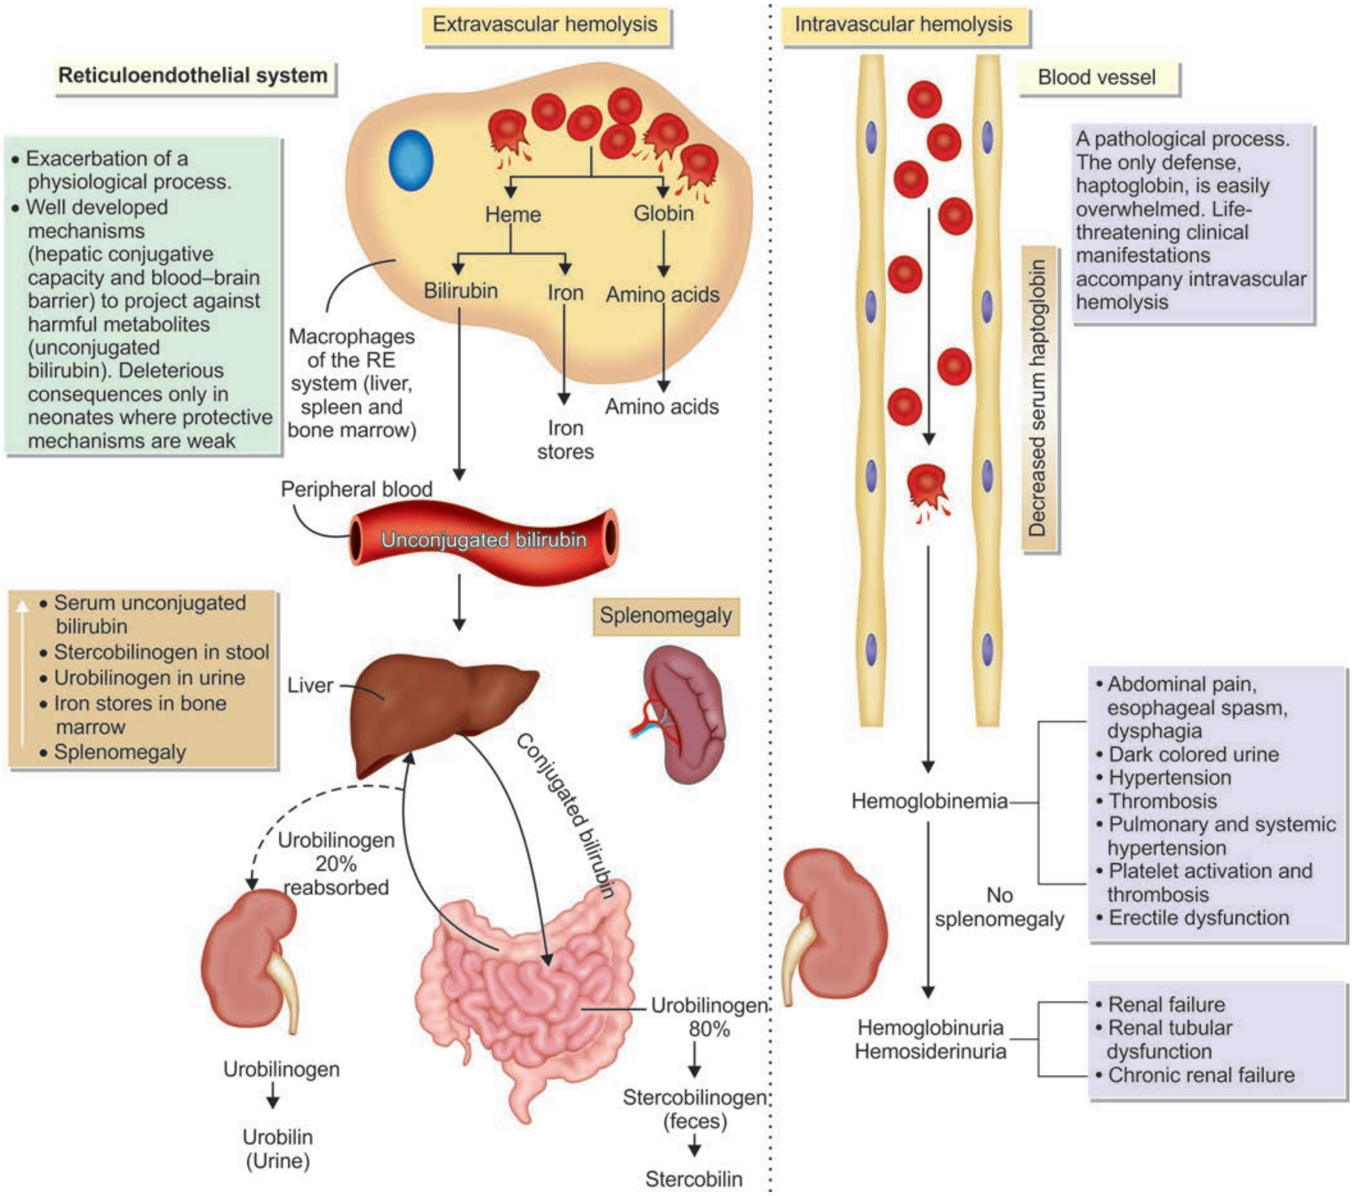
- Anemia
- Unconjugated hyperbilirubinemia (jaundice)
- Increased urobilinogen in urine (resulting from bilirubin breakdown in the intestine) leading to high-colored urine
- Shortened red cell life span (demonstrated by ^{51}Cr-labeled red blood cells)
- Other features:
    - In extravascular hemolysis: Splenomegaly usual
    - In intravascular hemolysis
        - Decreased plasma haptoglobin and hemopexin
        - Increased plasma lactic dehydrogenase (LDH)
        - Hemoglobinemia, hemoglobinuria, hemosiderinuria, and methemoglobinemia (in some)

2. Consequences of increased RBC production

- **Peripheral smear:** Reticulocytosis
- **Bone marrow:** Erythroid hyperplasia

3. Morphological features of damaged red cells

- **Peripheral smear:** For example, microspherocytes, elliptocytes, red cell fragments



Extravascular hemolysis
Intravascular hemolysis
Reticuloendothelial system
Blood vessel
• Exacerbation of a physiological process.
• Well developed mechanisms (hepatic conjugative capacity and blood–brain barrier) to project against harmful metabolites (unconjugated bilirubin). Deleterious consequences only in neonates where protective mechanisms are weak
Heme
Globin
Bilirubin
Iron
Amino acids
Macrophages of the RE system (liver, spleen and bone marrow)
Iron stores
Amino acids
A pathological process. The only defense, haptoglobin, is easily overwhelmed. Life-threatening clinical manifestations accompany intravascular hemolysis
Decreased serum haptoglobin
Peripheral blood
Unconjugated bilirubin
↑ • Serum unconjugated bilirubin
• Stercobilinogen in stool
• Urobilinogen in urine
• Iron stores in bone marrow
• Splenomegaly
Splenomegaly
Liver
Conjugated bilirubin
Urobilinogen 20% reabsorbed
Urobilinogen
Urobilin (Urine)
Urobilinogen 80%
Stercobilinogen (feces)
Stercobilin
Hemoglobinemia
No splenomegaly
• Abdominal pain, esophageal spasm, dysphagia
• Dark colored urine
• Hypertension
• Thrombosis
• Pulmonary and systemic hypertension
• Platelet activation and thrombosis
• Erectile dysfunction
Hemoglobinuria
Hemosiderinuria
• Renal failure
• Renal tubular dysfunction
• Chronic renal failure

FIG. 9.20: Mechanism and consequences of extravascular and intravascular hemolysis.

  - Coombs test
  - Osmotic fragility, sucrose lysis, and Ham's test
  - Heinz body preparation
  - Hemoglobin electrophoresis
  - Hemoglobin high-performance liquid chromatography (HPLC)
  - Measurement of enzyme activity
- Specific tests: Identification of specific cause of hemolysis is dealt under individual diseases.

Defects in Hemoglobin Production

Q. Write a short note on classification of disorders of hemoglobin (hemoglobinopathies/hereditary disorders of hemoglobin).

Hemoglobin defects may be in the form of production of abnormal (qualitative) or reduced production (quantitative) of normal hemoglobin **(Table 9.12)**. The term hemoglobinopathy, unless specified, usually indicates a qualitative hereditary disorder.

Sickle Cell Disease

Q. PA16.3 **Describe the pathogenesis, features, hematologic indices and peripheral blood picture of sickle cell anemia.**

TABLE 9.12: Classification of hemoglobin defects.

Qualitative defect in (structurally abnormal) hemoglobins	**Combined qualitative and quantitative defects in hemoglobins**
Hemoglobin S Hemoglobin C Hemoglobin D Punjab	Hemoglobin E Sickle-cell β-thalassemia
Quantitative defect in hemoglobins	**Acquired hemoglobinopathies**
Thalassemias (α, β-thalassemia)	Methemoglobinemia due to toxic exposures Carboxyhemoglobinemia

Sickle cell disease (SCD) is an important group of autosomal recessive hereditary disorders of hemoglobin characterized by production of defective hemoglobin synthesis called sickle hemoglobin (HbS). HbS imparts sickle shape to red cells on low oxygen tension or deoxygenation. The term sickle cell disease includes all entities associated with sickling of hemoglobin within the red blood cells. The major entities included are:

- **Sickle cell anemia (SS)** is a homozygous state in which both the β globin chains are abnormal.
- **Sickle cell trait (AS)** is a heterozygous state in which one gene is defective for HbS (abnormal) while the other gene is for HbA (normal).
- **Compound heterozygous** is characterized by both the β-globin chains having different abnormalities (e.g., Hb SC, HbS-β-thalassemia).

  In India, it is seen in certain tribes of South India, Assam, Bihar, and Odisha.

Etiology and Pathogenesis

Sickle cell anemia is caused by production of abnormal hemoglobin called sickle hemoglobin (HbS). In HbS, there is an adenine (A) to thymidine (T) substitution (GAG → GTG) in codon 6 of the β-globin gene. This point mutation results in **replacement of the normal glutamic acid residue by a valine** and alters the solubility or stability of the hemoglobin.

Pathogenesis

The change in the shape is due to dehydration, partly caused by potassium leaving the red cells via calcium-activated potassium channels called the Gárdos channel.

Deoxygenated HbS molecules are insoluble and polymerize to form pseudocrystalline structures known as "tactoids". Initially in an oxygenated state the RBCs are ovoid/boat shaped. Eventually when deoxygenation sets in the RBCs become rigid, deformed, and assume a characteristic sickle/crescent shape (sickle-shaped cells). Initially, on reoxygenation this process is reversible. But with repeated episodes of sickling, the RBCs eventually lose their membrane flexibility and become irreversibly sickled cells (ISCs). Factors that favor and hinder sickling are listed in **Table 9.13**.

TABLE 9.13: Factors affecting sickling.

Factors	*Favors sickling*	*Hinders sickling*
Other hemoglobins	-	HbA
	-	HbF
	HbC	-
Transit time in microvasculature	Slowing of bloodstream	-
MCHC	Increased MCHC	Decreased MCHC
Intracellular pH	Decreased pH	-
Other factors	Temperature above 37°C	-
	Infections	-
Oxygen tension	Low	High

Consequences of Sickling

Irreversibly sickled cells are dehydrated and dense and will not return to normal when oxygenated. Sickling can produce:

- **Microvascular occlusions:** Impaired passage of ISCs through the microcirculation, produce obstruction of small vessels, and lead to tissue ischemia and infarction
- **Hemolytic anemia:** It is due to shortened survival of the sickle cells which are destroyed by the reticuloendothelial system.

Clinical Features

Q. **Write a short essay/note on the complications of sickle cell anemia.**

The clinical features change as life advances.

In Children

- An infant till 3 months may be asymptomatic, because of the protective role of HbF. Since HbF disappears after the 3rd month, the majority of cases present after 3 months and before the 1st year of life.
- **Prone to infections:** Children are susceptible to acute infections with encapsulated organisms. Common infections are pneumococcal pneumonia, meningitis due to *S. pneumoniae*, and osteomyelitis due to *Salmonella*. Increased susceptibility to infections is because of hypofunction of spleen and defects in the alternative complement pathway which impair opsonization of encapsulated bacteria such as *pneumococci* and *Haemophilus influenzae*. Septicemia and meningitis are

the most common causes of death in children. Increased frequency of **osteomyelitis** is because of repeated bone infarcts which act as nidus for infection.

- In children, **bone involvement** may resemble acute osteomyelitis. They manifest as the **hand-foot syndrome and dactylitis** of the bones of the hands or feet or both. It is due to microinfarcts in the carpal and tarsal bones.
- **Sequestration crisis:** It usually occurs in children with chronically enlarged but normal functioning spleen. Sudden trapping of blood in the spleen or liver causes rapid enlargement of the organ with resultant drop in hematocrit and hypovolemic shock. This may require blood transfusions.
- **Changes in spleen:** Splenomegaly is observed during early childhood. Repeated episodes of splenic infarct result in atrophy of the spleen **(autosplenectomy)**.
- **Acute chest syndrome** can develop in both children and adults. It is due to infection or infarction in the lung and presents with pain in the chest, fever, respiratory distress, and hypoxemia.
- **Others** include acute coronary syndrome and stroke. Chronic hypoxia in children is responsible for generalized impairment of growth and development.

In Adults (Fig. 9.21)

Anemia: Patients develop severe hemolytic anemia which is exacerbated by secondary folate deficiency. Chronic anemia presents with fatigue, frequent infections, cardiomegaly, and systolic murmurs. Chronic hemolytic anemia causes increased levels of unconjugated (indirect) bilirubin, which predisposes to development of pigmented bilirubin gallstones. Cholelithiasis may lead to cholecystitis.

FIG. 9.21: Various effects of vascular occlusion and hemolysis in sickle cell anemia.

Q. Write a short essay/note on sickle cell crises.

- **Crises:** Irreversibly sickled cells have a shortened survival and plug vessels in the microcirculation. Any new syndrome or episode that develops rapidly in sickle cell anemia is termed crises. The protracted course of sickle cell anemia is frequently exacerbated by a variety of crises. Four types of crises are encountered. These are:
  - **i. Infarction (sickling) crisis (vaso-occlusive crisis):** Blockage of microcirculation by sickled red cells causes hypoxic injury and infarction.
    - It is the most common and the hallmark of sickle cell disease.
    - It clinically presents with acute, severe pain in the affected region. It commonly involves bones, lungs, liver, and spleen.
    - Bone: Sudden attacks of bone pain are due to ischemia and infarction. Avascular necrosis of the head of femur is also common.
    - Lung: Involvement presents with fever, cough, chest pain, and pulmonary infarcts and is known as *acute chest syndrome (dangerous).* These are sometimes initiated by a simple lung infection.
    - Spleen: Acute abdominal pain is caused by infarction of spleen and leads to autosplenectomy.
    - Other sites of infarction: Mesenteric infarction results in acute abdominal pain, cerebral infarctions result in hemiplegia, and infarction of renal papillae results in hematuria. Retinal microinfarcts result in loss of vision.
  - **ii. Aplastic crisis:** Temporary suppression of bone marrow erythropoiesis may develop due to an acute infection of erythroid progenitor cells by parvovirus B19.
  - **iii. Hemolytic crisis** is characterized by episodes of increased sequestration and destruction of red cells. It presents with marked increase in hemolysis with a sudden lowering of hemoglobin, rapid enlargement of liver and spleen, and reticulocytosis.
  - **iv. Sequestration crisis** (described above).

    Other crises encountered rarely are hypoplastic crisis and megaloblastic crisis (due to inadequate folate).

Q. Discuss the long-term complications of sickle cell anemia.

They are described in **Table 9.14**.

Investigations

- **Evidences of hemolysis**
- **Blood count:** Hb is in the range 6–8 g/dL with a high reticulocyte count (10–20%).
- **Peripheral smear:** The characteristic red cell which appears in smear is the **sickle cell (Fig. 9.22).** These appear as long, curved cells with pointed ends. Few ovoid/boat shaped RBCs are also seen. Features of hemolysis-reticulocytes/nucleated RBCs. Features of hyposplenism include: Howell–Jolly bodies (small nuclear remnants), **target cells** (due to red cell dehydration), **and ovalocytes**.
- **ESR is low** because sickle cells do not form rouleaux.
- **Sickling test** is induced by adding a reducing (oxygen-consuming) agent like 2% sodium metabisulfite or sodium dithionite to blood sample.
- **Sickle solubility test:** A mixture of HbS in a reducing solution (e.g., sodium dithionite) gives a turbid appearance because of precipitation of HbS, whereas normal Hb gives a clear solution.
- **Hemoglobin electrophoresis:** There is no HbA, 80–95% HbSS, and 2–20% HbF. HbS is slow-moving hemoglobin compared to HbA and HbF. In sickle cell trait (heterozygous state), HbS is 20–40% and the rest is HbA.
- Tests for iron overload: Serum ferritin levels, transferrin saturation, liver iron concentration using liver biopsy specimen, measurement of liver iron using MRI.
- Prenatal diagnosis can be done by analysis of fetal DNA obtained by amniocentesis or chorionic villous biopsy.

TABLE 9.14: Long-term complications of sickle cell anemia.

- **Impaired growth and development** with low weight and delayed sexual maturation
- **Chronic infarcts** of bones
- **Infections** of bones (*Salmonella* osteomyelitis), lungs, kidneys (pyelonephritis, chronic tubulointerstitial nephritis)
- **Leg ulcers**
- **Cardiac:** Cardiomegaly, arrhythmias, myocardial infarctions, and iron overload cardiomyopathy
- **Neurological:** Transient ischemic attacks, seizures, cerebral infarction, cerebral hemorrhage, and coma
- **Cholelithiasis**
- **Liver:** Chronic hepatomegaly, liver dysfunction
- **Priapism**
- **Iron overload** due to repeated transfusions
- **Eye:** Background retinopathy, proliferative retinopathy, vitreous hemorrhages, and retinal detachments
- **Pregnancy:** Spontaneous abortion, intrauterine growth retardation, preeclampsia, and fetal death

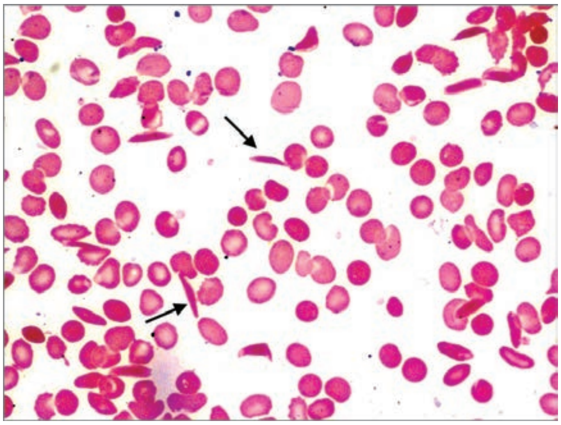

FIG. 9.22: Peripheral blood smear with sickle cells (arrows).

Management

General measures

Sickle cell disease is a chronic disorder which requires the following general measures:

- **Good nutrition** and folic acid supplementation (5 mg daily) are to be given to all patients with hemolysis.
- **Timely immunizations** against *Streptococcus pneumoniae*, seasonal influenza, *Neisseria meningitidis*, *Haemophilus influenzae type B*, and hepatitis B virus are recommended.
- **Antibiotic prophylaxis** with phenoxymethylpenicillin 500 mg daily starting at the age of 2 months. Older children do not routinely need continued antibiotic prophylaxis.
- Precipitating factors should be avoided or treated quickly. These include avoidance of cold, dehydration, and hypoxia.
- Prevention, prompt identification, and treatment of infections with antibiotics are required.

Anemia

- Transfusions should only be given for clear indications. Transfusion should not be given to patients with chronic stable anemia, those having minor surgery, or those having painful episodes without complications.
- **Indications for blood transfusion:** Transfusion is required to increase the oxygen-carrying capacity, replace the rigid, sickle-shaped RBCs with normal cells, and restore blood flow. Acute transfusions with packed RBCs can be life-saving and chronic transfusions reduce the incidence and severity of most complications.
  - Heart failure, TIAs, strokes, acute chest syndrome, and severe anemia due to aplastic crises and acute splenic sequestration
  - **Repeated transfusions** may be used to reduce the proportion of circulating HbS to less than 20% to prevent sickling, before elective operations and during pregnancy. Chronic RBC transfusion reduces the chance of recurrent ischemic stroke.

  - **Exchange transfusions** may be necessary in patients with severe or recurrent crises or before emergency surgery. Whether exchange transfusion is preferable to simple transfusion in the acute chest syndrome, stroke or other acute complications has not been established by clinical trials.
  - Infarction crises are managed with hydration, oxygen, analgesics, and transfusion with RBC concentrate in selected cases.
- **Iron overload:** With repeated transfusion, iron overload inevitably develops and can result in heart and liver failure and other complications. Iron overload is treated by using iron chelators (deferoxamine or deferasirox).

Hydroxycarbamide (hydroxyurea): It may be used as therapy for patients with severe symptoms. Hydroxyurea (10–30 mg/kg/day) increases HbF and suppresses the neutrophil and reticulocyte counts (which may play a major role in the pathogenesis of sickle cell crisis). Hydroxycarbamide reduces the episodes of pain, the acute chest syndrome, and the need for blood transfusions.

Senicapoc, a Gárdos channel inhibitor, prevented erythrocyte dehydration in clinical trials of patients with sickle cell disease. This drug has antiplasmodium activity.

Acute painful crisis

It requires supportive therapy with intravenous fluids, oxygen, antimicrobial agents, and adequate analgesia. Acute severe pain is treated with narcotic and analgesia (morphine) and milder pain can be relieved by codeine, paracetamol, and nonsteroidal anti-inflammatory drugs (NSAIDs). Inhaled nitric oxide inhibits platelet function, reduces vascular adhesion of red cells, and is also a vasodilator. It can provide short-term pain relief and is shown to reduce opiate requirements in acute painful episodes. But it should be restricted to experts to avoid hypoxia and respiratory depression. Nasal oxygen should be employed as appropriate to protect arterial saturation.

Acute chest syndrome is treated with antibiotics, maintenance of arterial oxygenation, pain relief, bronchodilators, and, if required, exchange transfusion.

Chronic leg ulcers: They are treated with elevation of limb, daily dressings with zinc sulfate, and exchange transfusion in extreme cases.

Curative

- **Bone marrow/stem cell transplantation:** In children and adolescents younger than 16 years of age who have severe complications (strokes, recurrent chest syndrome, or refractory pain), bone marrow/stem cell transplantation can provide definitive cure.
- **Gene therapy** is intensively pursued, but no safe measures are currently available.

Hereditary Spherocytosis

Q. Write a short note on hereditary spherocytosis (HS).

- **It is the most common inherited hemolytic anemia in adults**
- **Autosomal dominant** inheritance is present in more than 75% cases
- Defect in the RBC membrane is due to cytoskeleton protein (e.g., **ankyrin, band 3, spectrin, or band protein 4.2**) deficiency.
- This results in red cells losing part of the cell membrane as they pass through the spleen and assume a spheroidal shape (spherocytes) that is less deformable (rigid) and more susceptible to osmotic lysis.
- Red cells have a decreased life span of as low as 10–20 days.

Clinical Features

- Disease may present during anytime from the neonatal period to adulthood.
- **Family history:** Most (75%) HS are inherited as autosomal dominant trait and there is a strong family history of anemia, jaundice, splenomegaly, and cholelithiasis.
- **Anemia** is usually mild to moderate.
- **Jaundice:** There are intermittent attacks of jaundice.
- **Splenomegaly:** Moderate splenic enlargement is characteristic and constant feature.
- **Children:** Growth retardation due to hemolysis and bone changes due to marrow hyperplasia are found in children.
- **Adults:** Anemia, intermittent jaundice, and moderate splenomegaly are found in adults.
- Complications of hereditary spherocytosis are listed in **Box 9.4**.

Investigations

- **Anemia:** It is usually mild, but occasionally can be severe.
- **Peripheral blood film** shows **spherocytes (Fig. 9.23)** and reticulocytes/nucleated RBCs. **MCHC is increased.**
- **Demonstration of a hemolytic state:** Raised serum bilirubin and urinary urobilinogen

Box 9.4: Complications of hereditary spherocytosis.

- Cholelithiasis (pigment gallstones)
- Chronic leg ulcers
- Aplastic crisis due to parvovirus B19 infection
- Hemolytic crisis (rare)

- Specific diagnostic tests are listed in **Box 9.5**. Increased osmotic fragility may be absent in mild cases and may be positive in autoimmune hemolytic anemia.
- **Negative Coombs test**
- **Strong family history will be present.**

Treatment

- Splenectomy is the treatment of choice and should not be done before the age of 6 years. Splenectomy corrects the anemia and its complications but increases the risk of infections. Hence, it should be preceded by *pneumococcal* and *Haemophilus influenzae* immunization and followed by lifelong penicillin prophylaxis.
- Folic acid supplementation in patients without splenectomy is recommended.
- Regular blood transfusions are required in few patients with severe disease.
- Cholecystectomy is indicated only for symptomatic gallstones.

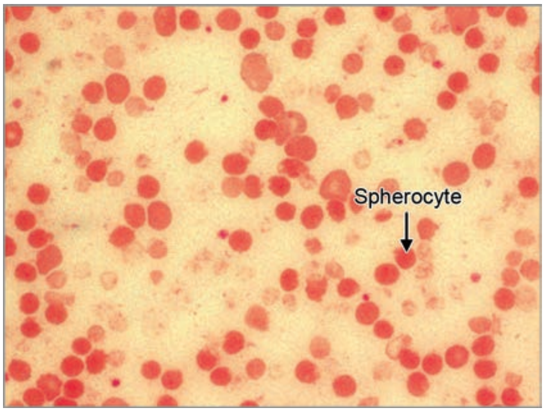

FIG. 9.23: Peripheral blood smear with numerous spherocytes (arrow) in hereditary spherocytosis.

Thalassemia Syndrome

Q. PA16.3 Describe the pathogenesis, features, hematologic indices and peripheral blood picture of thalassemia.

Thalassemia syndrome is a heterogeneous group of inherited disorders which result from reduced or absence of synthesis of one of the globin chains (either α or β globin chain).

Classification

Thalassemic syndromes are mainly classified into two main types depending on the defective globin chain α- or β-thalassemia **(Box 9.6)**. The mode of inheritance is autosomal recessive. Rarely, *HBB* gene mutation is inherited as autosomal dominant.

Box 9.5: Specific diagnostic tests for hereditary spherocytosis.

- Osmotic fragility testing
- Ektacytometry
- Acidified glycerol lysis test
- Cryohemolysis test
- Eosin-5-maleimide binding test

Box 9.6: Classification of thalassemic syndromes.

β-thalassemia syndromes: Based on the genetic defect (β^+ or β^0):

β-thalassemia major (Cooley's Anemia)	β-thalassemia intermedia	β-thalassemia minor
Homozygous disorder. Most severe form Either no production of β-chains (β^0) or it is markedly reduced (β^+) Anemia—severe, transfusion dependent High level of HbF in the blood	Double heterozygous state Anemia—moderately severe, not transfusion dependent	Also called β-***thalassemia trait*** Heterozygous state Asymptomatic with mild anemia

α-thalassemia syndromes

Each cell has four genes coding for α-globin, two on each chromosome. Each gene contributes to 25% of the total α-globin chains.
Severity depends on the number of genes deleted or affected. Deleted genes may vary from 1 to 4.

1 gene affected	2 genes affected	3 genes affected	4 genes affected
Silent carrier state	α-thalassemia trait	HbH disease	Hb Bart's hydrops fetalis Incompatible with life—stillbirths or die shortly after birth

α-thalassemia Syndromes

Each cell has four genes coding for α-globin, two on each chromosome. Each of the four α-globin genes normally contributes 25% of the total α-globin chains. Severity of α-thalassemia depends on the number of α-globin genes deleted or affected. Deleted genes may vary from 1 to 4.

Classical thalassemia syndromes (genotypes and laboratory findings) are presented in **Table 9.15**.

- Silent carrier state develops with deletion of one α-chain gene.
- α-thalassemia trait: It is due to deletion of two α-genes.
- HbH disease: It is due to deletion of three α-genes.
- Hb Bart's hydrops fetalis: It develops if all four genes are absent. It is incompatible with life and the infants are either stillborn or die shortly after birth. They are pale, edematous, and have large liver and spleen.

TABLE 9.15: Classical thalassemia syndromes (genotypes and laboratory findings).

Syndrome	*Genotype*	*Typical findings on CBC*	*Hemoglobin analysis (HPLC or electrophoresis)*
Hydrops fetalis with Hb Barts	(–€–€/ –€–€)	Severe microcytic anemia with hydrops fetalis; usually fatal in utero	Hb Barts (γ globin tetramers); Hb Portland (embryonic hemoglobin); no HbF, HbA, or HbA_2
HbH disease	(α€– / – –) or (α^{t} –€/ –€–)	Moderate microcytic anemia	HbH (up to 30%); HbA_2 (up to 4%)
Minor	(α€–€/α€–€) or (α α /–€–)	Mild microcytic anemia	Hb Barts (3–8%)
Silent carrier	(α α /α^{-})	Normal hemoglobin, normal MCV	Normal
Major (transfusion-dependent)	β^0/β^0 or β^0/β^+	Severe microcytic anemia with target cells (typical Hb 3–4 g/dL)	HbA_2 (5% or more); HbF (up to 95%); no HbA
Intermedia (nontransfusion- dependent)	B^+/β^+	Moderate microcytic anemia	HbA_2 (4% or more); HbF (up to 50%)
Minor (also called trait or carrier)	β/β^0 or β/β^+	Mild microcytic anemia	HbA_2 (4% or more); HbF (up to 5%)

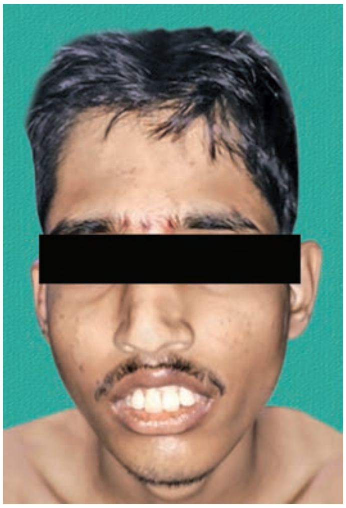
β-*thalassemia Major*

Q. Discuss the clinical features, salient investigations, diagnosis, and management of β-thalassemia major (Cooley's anemia).

- β-thalassemia major (Mediterranean or Cooley's anemia) is the homozygous form of β-thalassemia characterized by absent or reduced synthesis of β-chain.
- It is most common in Mediterranean countries and parts of Africa and Southeast Asia. In India, it is common among certain communities (e.g., *Sindhi*, *Punjabi*, *Gujarati*, *Parsee*) in North India and less common in South India.
- **Anemia** is produced due to diminished synthesis of HbA, ineffective erythropoiesis, and extravascular hemolysis.
- **Consequences of ineffective erythropoiesis:**
    - Marked erythroid hyperplasia: Severe hemolytic anemia stimulates erythropoietin (EPO) production by kidney leading to marrow erythroid hyperplasia.
    - Changes in the bone: Thalassemic facies and hair-on-end appearance of skull X-ray.
    - Extramedullary hematopoiesis.

Clinical Features

- **Severe anemia:** Infants with thalassemia major are well at birth but develop moderate-to-severe anemia 6–9 months after birth, when hemoglobin synthesis switches from HbF to HbA.
- **Retardation of growth and development:** Untreated/untransfused children **fail to thrive** (growth retardation) and die early within 4–5 years of age from the effects of anemia. They are **susceptible to recurrent bacterial infections.**
- **Changes in bone:** In those who survive longer, bone marrow hyperplasia causes expansion and widening of marrow and gives the **classical X-ray changes**.
    - **Thalassemic (Chipmunk) facies (Fig. 9.24):** Due to enlargement and distortion of craniofacial bones (frontal bossing of the skull, prominent malar eminence, depression of bridge of nose, and hypertrophy of the maxillae, which tends to expose the upper teeth)
    - **Hair-on-end (crew-cut) appearance (Fig. 9.25):** It can be seen in the skull X-ray due to new bone formation.
- **Splenomegaly** may be massive and enlarges up to 1,500 g due to hyperplasia and extramedullary hematopoiesis.
- Liver (hepatomegaly) and lymph nodes also may show extramedullary hematopoiesis.
- **Hemosiderosis:** Although blood transfusions improve the anemia, iron overload will lead to hemosiderosis and secondary hemochromatosis. This may be due to increased gastrointestinal absorption of iron. It damages organs such as heart, liver, and pancreas.
    - Cardiac hemosiderosis results in arrhythmias, heart blocks, and congestive heart failure.
    - Hepatic hemosiderosis results in cirrhosis.
    - Pancreatic hemosiderosis results in diabetes.



[redacted]

FIG. 9.24: Chipmunk facies in thalassemia.

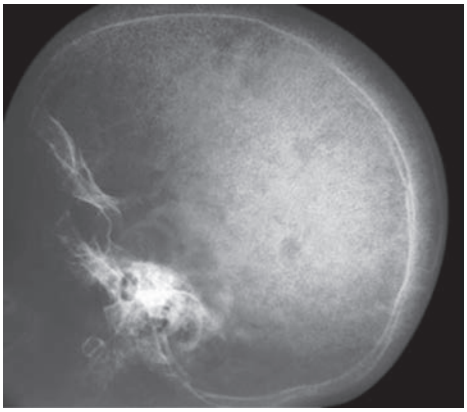


FIG. 9.25: Skull X-ray showing crew-cut appearance due to new bone formation.

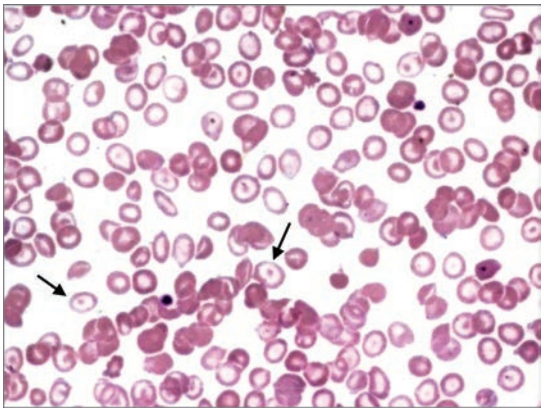

FIG. 9.26: Peripheral blood smear in β-thalassemia showing target cell (arrows).

  - Pituitary: It leads to hypogonadotropic hypogonadism.
- Treated patients can survive beyond 40 years of age

Investigations

- **Peripheral smear (Fig. 9.26):** Marked **microcytic hypochromic anemia** with moderate to marked anisocytosis and poikilocytosis. Many **target cells** (hemoglobin collects in the center of RBCs). Evidence of hemolysis-polychromatophils (reticulocytes) and nucleated red cells are visible.
- **HbF level is increased** (30–92%) on hemoglobin electrophoresis.
- **There is markedly reduced or absent HbA**.
- Osmotic fragility test shows increased resistance to hemolysis.
- Skull radiograph shows a "**hair-on-end"/crew-cut appearance.**
- There is evidence of thalassemia minor in both parents.
- **Red cell distribution width (RDW)** is within normal limits (in contrast to iron deficiency anemia).

Management

- **Aims of treatment:** To suppress ineffective erythropoiesis, prevent deformities of bone, and allow normal activity and development. Blood transfusions may be required every 4–6 weeks. **Hypertransfusion** to maintain Hb level between 10 and 12 g/dL is probably adequate. It decreases the effect of chronic anemia and prevents abnormal growth and development. **Supertransfusion** wherein the Hb level is maintained at 12 g/dL is designed to completely suppress hematopoiesis.
- **Maintenance of Hb level:** Long-term folic acid supplement and regular blood transfusions are recommended to keep the Hb >10 g/dL.
- **Treatment of iron overload:** The iron-chelating agent, **desferrioxamine** (administered parenterally), is indicated if serum ferritin >1,500 µg/L. Ascorbic acid 200 mg daily along with desferrioxamine increases the urinary excretion of iron in response to desferrioxamine. Deferiprone and deferasirox are oral iron chelators.
- **Splenectomy** is indicated in children with massive symptomatic splenomegaly and those with progressively increasing requirement of blood transfusion or hypersplenism.
- **Bone marrow transplantation is done** in young patients.
- **Management of associated complications:** For example, congestive heart failure and endocrinopathies.

β-thalassemia Minor (Trait)

Q. Write a short essay/note on thalassemia minor (trait) and thalassemia intermedia.

- β-thalassemia minor is more common than β-thalassemia major.
- It is a common carrier (heterozygous) state and is usually **asymptomatic.**
- Anemia is mild or absent.
- **Peripheral blood smear** shows severe microcytic and hypochromic red cells with target cells. It may be confused with iron deficiency.
- Serum ferritin and the iron stores are normal.
- **Hb electrophoresis** usually shows a raised HbA_2 (3.5–7.5%) and often a raised HbF.
- Iron should not be given to these patients unless there is associated iron deficiency.

- **Genetic counseling is recommended** to prevent transmission of carrier state from both parents.
- **Prenatal diagnosis** by chorionic villi biopsy at 11 weeks is done.
- It may be associated with other hemoglobin abnormalities. Examples include HbS/β-thalassemia, HbC/β-thalassemia, and HbE/β-thalassemia.

β-thalassemia Intermedia

- It is a clinical entity in which patients have a clinical spectrum intermediate between thalassemia trait and thalassemia major.
- Patients are anemic and generally have mild-to-moderate anemia (Hb 7–9 g/dL).
- It is not transfusion dependent.
- Mild splenomegaly, bone deformities, gallstones, and chronic leg ulcers may be seen.
- Folic acid supplementation should be given.

Glucose-6-Phosphate Dehydrogenase Deficiency

Q. Discuss the etiology, precipitating causes, clinical features, investigations, and management of glucose-6-phosphate dehydrogenase deficiency.

- Glucose-6-phosphate dehydrogenase (G6PD) is the initial and rate-limiting step in the hexose monophosphate (HMP) shunt of the Embden–Meyerhof pathway.
- G6PD is the only source of NADPH, and NADPH is required for the generation of glutathione (GSH), which protects red cells from oxidative stress **(Fig. 9.27)**.
- G6PD-deficient patients may develop acute hemolytic anemia after exposure to any oxidative stress.
- G6PD deficiency is an X-linked disorder and is the most common enzyme deficiency.
- RBCs deficient in G6PD are unable to keep glutathione in a reduced state. These RBCs are susceptible to injury by oxidants of both exogenous and endogenous origins.
- More than 400 G6PD genetic variants are known, but most are harmless. The three common variants are:
    - **G6PD A:** The minus sign indicates absence of enzyme activity. Hemolysis develops when exposed to oxidant drugs (primaquine) or infections. The hemolysis is mild to moderate and is limited to the older RBCs.
    - **G6PD (B)** or **G6PD Mediterranean/Wild type:** It is prevalent in the Middle East and is the severe form of deficiency. This is the most common variant seen in India. Other variants in India include G6PD Kerala-Kalyan and G6PD Odisha.
    - **G6PD Canton** is seen in Chinese.

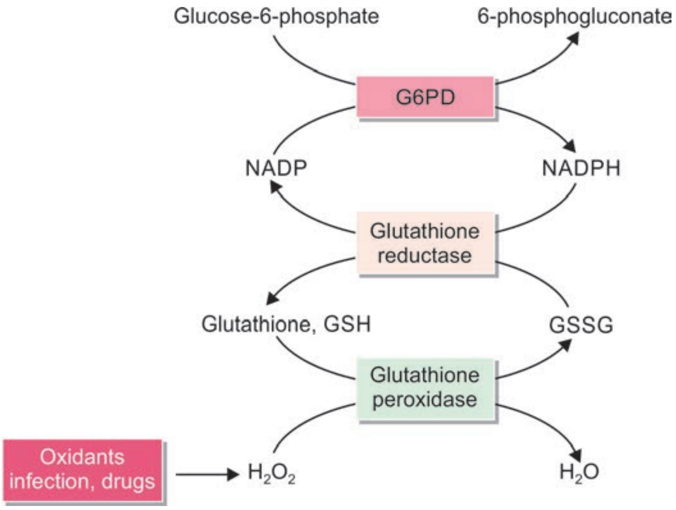

FIG. 9.27: Role of G6PD against injury by oxidants.

Clinical Features

- Most patients with G6PD deficiency remain clinically asymptomatic; however, all of them have an increased risk of developing clinically significant syndromes: (1) acute hemolytic anemia (AHA), (2) neonatal jaundice (NNJ), and rarely, (3) chronic nonspherocytic hemolytic anemia (CNSHA).
- **Acute hemolytic anemia:** Due to intravascular hemolysis, acute hemolytic anemia is the most dramatic clinical presentation of G6PD deficiency. It develops after exposure to an oxidative stress and the triggers include:
    - **Drugs:** Antimalarials (primaquine, quinine, chloroquine), sulfonamides (sulfamethoxazole), antibacterial/antibiotics (cotrimoxazole, nitrofurantoins), antipyretics/analgesics (acetanilide phenazopyridine), dapsone, quinidine, methylene blue, nitrofurantoins, etc.
    - **Fava beans**
    - **Infections:** Viral and bacterial.

The exposure to triggering agents produces hemolytic attack with rapid development of anemia and hemoglobinuria (cola colored urine). Rarely acute renal failure may develop. The onset can be extremely abrupt, especially following ingestion of the broad beans **(favism)** in children.

- **Neonatal jaundice** is a feature of Mediterranean type. Hemolytic anemia is very rarely severe. Jaundice may be due to decreased hepatic elimination of bilirubin. Severe neonatal jaundice, if not adequately treated with phototherapy, may result in kernicterus or even death.
- **Chronic nonspherocytic hemolytic anemia (CNSHA):** Develops in a very small minority of patients. Such a patient is always a male and usually has a history of severe neonatal jaundice and chronic anemia. The degree of chronic anemia is variable and some patients may have required intermittent transfusions. They have reticulocytosis, gallstones, and splenomegaly. Hemolysis is mainly extravascular.

G6PD deficiency (African variety) has a protective effect against *Plasmodium falciparum*.

Laboratory Findings (Investigations)

- **Evidence of intravascular hemolysis:** Raised unconjugated bilirubin, hemoglobinemia, hemoglobinuria, high LDH, and low or absent plasma haptoglobin.
- **Anemia:** It usually ranges from moderate to extremely severe. It is due to both intravascular and extravascular hemolysis.
- **Peripheral blood film:**
  - Normocytic and normochromic with evidence of hemolysis-polychromasia (reticulocytosis), spherocytes and red cell fragments (in severe cases).
  - Bite (blister) cells are red cells in which parts of them appear bitten away (precipitated Hb is phagocytosed by the splenic macrophages).
  - Heinz bodies consist of membrane-bound precipitates of denatured hemoglobin (methemoglobin) and represent oxidative damage. They are seen as dark purple inclusions within red cells and can be demonstrated by supravital staining with methyl violet.
- **Confirmation of diagnosis:** By estimating G6PD activity of the red cell. This should be estimated several days after the acute hemolytic episode. This is because if done during or immediately after acute hemolysis, it may give a falsely normal value as the young red cells and reticulocytes have near-normal G6PD levels.

Treatment (management) of G6PD deficiency

- **Removal of the triggering agent** and avoiding its further exposure to triggering factors in previously screened patients. Once the cause is recognized, in most cases no specific treatment is required. Management of neonatal jaundice is similar to any other cause of neonatal hyperbilirubinemia.
- Supportive therapy for anemia:
  - Blood transfusion
  - Regular folic acid supplements in CNSHA
- Treatment of infection and genetic counseling

Miscellaneous Anemias

Q. Write a short essay/note on the causes and management of normocytic anemia.

Normocytic Normochromic Anemia

Normocytic normochromic anemia is characterized by the normal size of the RBCs and normal MCV (**Table 9.16**).

TABLE 9.16: Various causes of normocytic normochromic anemia.

Decreased red cell production	*Increased red cell loss or destruction*
➢ Anemia of chronic disease ➢ Chronic renal failure ➢ Chronic liver disease ➢ Endocrine disorders – Hypopituitarism – Hypothyroidism – Hypoadrenalism ➢ Hematological disorders – Marrow hypoplasia or aplasia – Myeloproliferative neoplasms – Myelofibrosis – Sideroblastic anemia	➢ Acute blood loss ➢ Hypersplenism ➢ Hematological disorders – Hemoglobinopathies (sickle cell disease) – Hereditary spherocytosis – Glucose-6-phosphate dehydrogenase (G6PD) deficiency – Microangiopathic anemias [disseminated intravascular coagulation (DIC), thrombotic thrombocytopenic purpura, hemolytic uremic syndromes] – Autoimmune hemolytic anemia – Paroxysmal nocturnal hemoglobinuria
Expansion of plasma volume: Pregnancy	

Management: Treatment of the underlying disease.

Differential Diagnosis of Hypochromic Microcytic Anemias

Q. Describe the etiology, investigations, and differential diagnosis of hypochromic microcytic anemia.

Table 9.17 shows the differentiating features of hypochromic microcytic anemias.

TABLE 9.17: Various differentiating features of hypochromic microcytic anemias.

	Iron deficiency anemia	*Thalassemia trait*	*Anemia of chronic disease*	*Sideroblastic anemia*
MCV	Reduced	Very low for degree of anemia	Low normal or normal	Inherited—low Acquired—high
Serum iron ***(normal 60–170 μg/dL)***	Reduced	Normal to high	Reduced	Raised
Serum total iron binding capacity ***(normal 300–350 μg/dL)***	Raised	Normal	Reduced	Normal
Serum ferritin ***(normal 15–300 μg/dL)***	Reduced	Normal	Normal or raised	Raised
Serum-soluble transferrin receptors	Increased	Normal or raised	Normal	Normal or raised
Iron in marrow	Absent	Present	Present	Present
Iron in erythroblasts	Absent	Present	Absent or reduced	Ring forms
Hemoglobin A$_2$ (normal <3%)	Reduced	Increased	Normal	Reduced

Sideroblastic Anemias

Q. Write a short essay/note on sideroblastic anemias.

Definition

Sideroblastic anemias are rare inherited or acquired disorders of refractory anemia, characterized by:

- A dimorphic peripheral blood picture. Microcytic hypochromic red cells in hereditary form and macrocytic in the acquired forms of the disease mixed with normochromic cells. The presence of siderocytes (non-hemoglobin iron containing RBCs) can be appreciated by Wright's stain.
- Presence of ring sideroblasts, excess storage iron in the bone marrow, and increased serum iron concentration. The diagnostic feature is the presence of ring sideroblasts in the bone marrow. The iron-laden mitochondria surround the nucleus of erythroblasts and appear as the pathognomonic "rings" of iron granules with Prussian blue staining (Perls' reaction).
- Tiny iron-containing inclusions, called Pappenheimer bodies, are found in the red blood cells (stain positively by Prussian blue staining).
- Ineffective erythroid hyperplasia due to nonviable sideroblasts.

Classification of Sideroblastic Anemia (Box 9.7)

Microcytosis is often seen in hereditary forms, but normochromic normocytic or even macrocytic RBCs may be seen, especially in the setting of myelodysplasia or in a rare X-linked hereditary form known as Pearson's syndrome.

Box 9.7: Classification of sideroblastic anemia.

Inherited sideroblastic anemia: X-linked disease—transmitted by females

Acquired sideroblastic anemia
Primary: Myelodysplasia

Secondary	
Drugs, e.g., isoniazid, cycloserine, chloramphenicol, busulfan, D-penicillamine	Myeloproliferative neoplasms
Alcohol abuse	Myeloid leukemia
Lead toxicity	Primary pyridoxine deficiency
	Others (e.g., rheumatoid arthritis, carcinoma)

Treatment

- Withdrawal of causative agent: Some patients respond when the drugs, toxins, or alcohol are withdrawn.
- Occasional cases may respond to pyridoxine or folic acid.
- Supportive treatment with transfusions.
- Erythropoietin can also be given.

Hereditary sideroblastic anemias

Hereditary sideroblastic anemias comprise a clinically, genetically, and hematologically heterogeneous group of rare disorders. It may be inherited as an X-linked or an autosomal (dominant or recessive) disorder. These patients generally have low levels of δ-aminolevulinic acid synthase (ALAS) enzymes in the normoblasts leading to defective synthesis of hemoglobin.

Paroxysmal Nocturnal Hemoglobinuria

Q. Write a short essay/note on paroxysmal nocturnal hemoglobinuria (PNH).

Paroxysmal nocturnal hemoglobinuria is a rare **acquired nonmalignant, genetic defect due to mutation in the hematopoietic stem cell.** These **clones of red cells are particularly sensitive to destruction by activated complement.** Platelets and granulocytes are also affected and there may be thrombocytopenia and neutropenia.

Etiology and Pathogenesis

The stem cells and their progeny have **deficient synthesis of glycosylphosphatidylinositol (GPI) linked proteins,** namely: (1) decay-accelerating factor or CD55 and (2) membrane inhibitor of reactive lysis or CD59. This is most important and a potent inhibitor of C3 and prevents activation of the alternative complement pathway on their membrane. In PNH, the red cells are abnormally sensitive to complement-mediated intravascular hemolysis. The severity of hemolysis is proportional to the number of these abnormal red cells. The molecular basis of PNH is the mutations in the *pig-A* (phosphatidylinositol glycan protein A) gene responsible for synthesis of the GPI anchor.

Clinical Features

- It is mainly seen in adults, usually in middle age.
- Both sexes are equally affected.
- **Intravascular hemolysis**: Characteristically, only the urine voided at night (nocturnal) and in the morning on waking is dark in color. The hemolysis is due to reduced pH of blood during sleep which enhances the activity of complement. Hemoglobin in acidic urine is converted into acid hematin which colors the urine dark brown. Urinary iron loss may be sufficient to cause iron deficiency. Other features include abdominal pain/dysphagia, erectile dysfunction, pulmonary hypertension, and renal insufficiency.
- Mild jaundice and mild hepatosplenomegaly are often present.
- **Thrombosis:** It is very common involving the hepatic (Budd–Chiari syndrome), portal, or cerebral veins and is often the leading cause of death.
- It may begin or progress to aplastic anemia.

Diagnosis

- **Peripheral smear:** Anemia, reticulocytosis, varying degrees of thrombocytopenia and leukopenia (pancytopenia) are diagnosed.
- Features of **intravascular hemolysis** such as raised bilirubin, hemoglobinemia, hemoglobinuria, and hemosiderinuria are present.
- **Bone marrow** is sometimes hypoplastic (or even aplastic) despite hemolysis.
- Diagnosis is confirmed by Ham's test and sucrose lysis test. These tests cannot reliably detect small populations of affected red cells.
    - **Ham's acidified serum test:** Checks whether red blood cells become more fragile when they are placed in mild acid. Acidification of serum activates alternate complement pathway.
    - **Sucrose hemolysis test:** A PNH patient's red cell undergoes lysis when incubated in low-ionic-strength solution of sugar sucrose (which activates alternate complement pathway). It can be positive in megaloblastic anemia and autoimmune hemolytic anemia.
- **Flow cytometry:** It detects red cells that are deficient in **GPI-linked proteins (CD55 and CD59).** It is a rapid and sensitive test for diagnosis.
- *Neutrophil alkaline phosphatase* **(NAP) score:** *NAP score is reduced (normal 40–100), because NAP is a GPI-linked protein.*
- **Progress:** PNH patients are also at an increased risk for developing aplastic anemia or acute myelogenous leukemia or a myelodysplastic syndrome.

Treatment

- Supportive measures: Blood transfusions (for patients with severe anemia) and control of infections
- Iron therapy is often necessary due to loss in urine.
- **Anticomplement therapy: Eculizumab** is a humanized monoclonal antibody that prevents the cleavage of C5 (thereby the formation of the membrane attack complex) and reduces intravascular hemolysis, hemoglobinuria, and the need for transfusion.
- Long-term anticoagulants may be necessary for patients with recurrent thrombotic episodes.
- Steroids may be useful in some cases.
- Bone marrow (stem cell) transplantation is curative.

Methemoglobinemia

Q. Write a short essay/note on methemoglobinemia.

- Normal oxygen transport depends on the maintenance of iron in hemoglobin in ferrous (reduced) form (Fe^{++}).
- **Methemoglobin (Hi)** is a hemoglobin in which the iron is in oxidized ferric form and unable to combine with oxygen. Normal RBCs contain less than 1% methemoglobin. Increased amount of methemoglobin in the RBCs is called methemoglobinemia.
- Clinically, when methemoglobin level is more than 1.5 g/dL, the patient develops cyanosis. At higher levels, it produces headache, weakness, and breathlessness. At higher methemoglobin levels, respiratory depression, altered sensorium, coma, shock, seizures, and death may occur.

Causes of Methemoglobinemia

- **Hereditary:** Deficiency of methemoglobin reductase, cytochrome B5 reductase deficiency
- **Acquired:** Exposure to certain drugs and toxins (e.g., nitrites and nitrates, nitrofurantoin, chloroquine, naphthalene, local anesthetics (procaine, lidocaine), primaquine, dapsone, sulfa drugs phenacetin, phenazopyridine, metoclopramide, nitroglycerine], copper sulfate

Treatment

- Methemoglobin reductase deficiency: Oral methylene blue or ascorbic acid
- Severe methemoglobinemia: Intravenous methylene blue. Ensure adequate tissue oxygenation.

Autoimmune Hemolytic Anemia

Autoimmune hemolytic anemias (AIHA) are a group of acquired disorders resulting from increased red cell destruction due to red cell autoantibodies.

Q. Write a short essay/note on autoimmune hemolytic anemias.

Q. PA16.4 Describe the etiology pathogenesis, hematologic indices and peripheral blood picture of Acquired hemolytic anemia

Classification of Autoimmune Hemolytic Anemia

It may be classified based on:

1. Type of antibody: Interaction of the autoantibody with the red cell antigen is dependent on the temperature, i.e., warm or cold type **(Box 9.8)**.
2. Etiology **(Box 9.9)**.

Warm antibody immunohemolytic anemia

- Warm antibody type is the most common type (50–70%).
- The antibodies are mainly of **IgG** type. The antibodies combine with red cell antigen at 37°C and hence known as a **warm antibody**.

Clinical features

- They may occur at all ages and in both sexes, although most frequent in middle-aged females.
- They may present with anemia, jaundice, hepatosplenomegaly, and manifestations and underlying disease.
- Exclude underlying systemic lupus erythematosus, lymphoma, and leukemia.

Box 9.8: Classification of autoimmune hemolytic anemia according to type of antibody.

Based on antibody type

Warm antibody type (IgG antibodies active at 37°C)

- **Primary (idiopathic)**
- **Secondary**
  - Autoimmune disorders (systemic lupus erythematosus and others)
  - Drugs (e.g., Methyldopa, penicillins, quinidine)
  - Lymphomas—Hodgkin's lymphoma, chronic lymphocytic leukemia

Cold agglutinin type (IgM antibodies active at 4–18°C)

- **Acute**
  - Mycoplasma infection
  - Infectious mononucleosis
- **Chronic**
  - Idiopathic
  - Lymphomas

Cold hemolysin type (Donath–Landsteiner antibodies)

Rare; seen mainly in children; usually postviral

Box 9.9: Classification of autoimmune hemolytic anemia based on etiology.

Based on etiology

Idiopathic (50%)

Secondary (50%)

- Drugs, e.g., methyldopa, penicillins, quinidine
- Mycoplasma infection
- Infectious mononucleosis
- Autoimmune disorders (systemic lupus erythematosus and others)
- Lymphomas

Investigations

- Evidence of hemolytic anemia
- Spherocytosis (due to red cell damage) and macrocytes in peripheral blood
- Direct antiglobulin (Coombs) test is positive.
- Autoantibodies may have specificity for the Rh blood group system (e.g., for the e antigen).
- In some cases, **autoimmune thrombocytopenia** and/or neutropenia may also be present (Evans' syndrome).

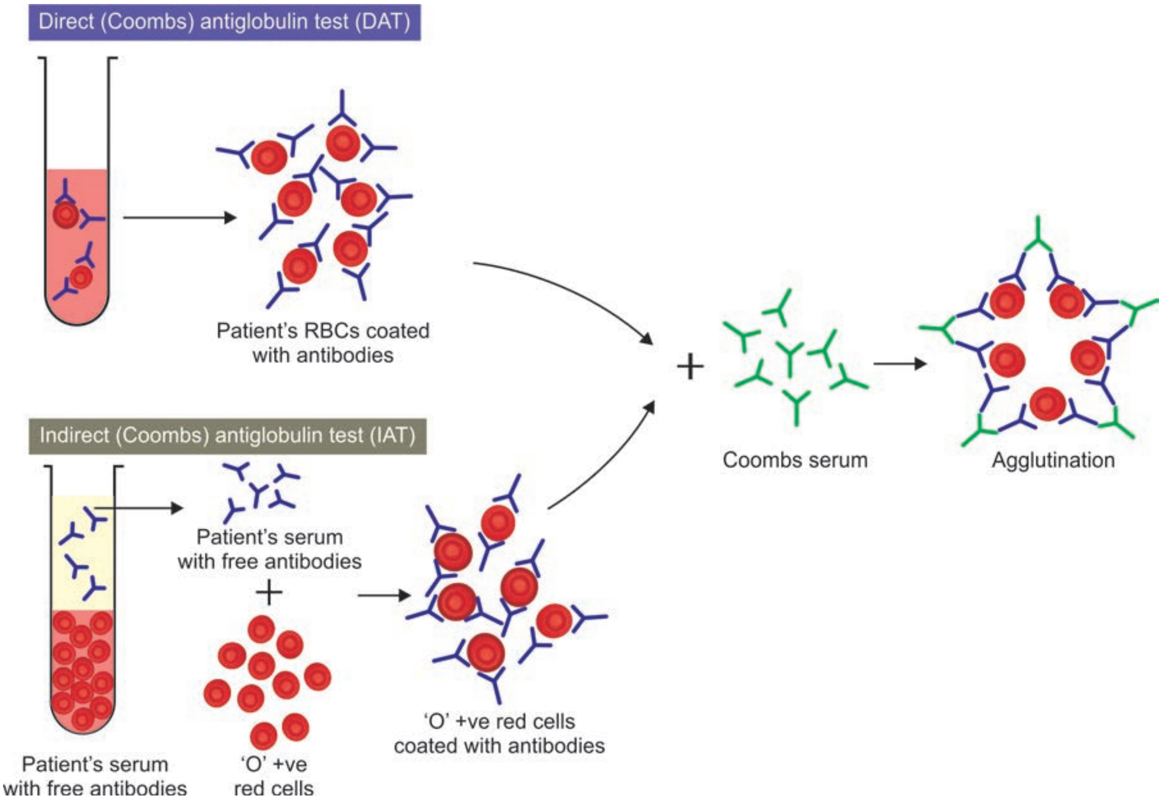
Antiglobulin (Coombs) Test (Fig. 9.28)

Q. Write a short essay/note on significance of Coombs test.

There are two types, namely, direct and indirect.

Q. Write a short note on the Coombs test.

1. **Direct** (Coombs) **antiglobulin test (DAT)** detects the immunoglobulin (IgG) antibody and/or C3 complement (usually C3d) on a patient's RBCs. **A patient's red cells** are washed and suspended in saline. Antiglobulin serum is added. Agglutination of red cells indicates the presence of antibodies on the surface of RBCs and interpreted as positive DAT.



Direct (Coombs) antiglobulin test (DAT)
Patient's RBCs coated with antibodies
Indirect (Coombs) antiglobulin test (IAT)
Patient's serum with free antibodies
+
Patient's serum with free antibodies
'O' +ve red cells
'O' +ve red cells coated with antibodies
+
Coombs serum
Agglutination

FIG. 9.28: Method of direct and indirect methods of antiglobulin test (Coombs test).

False negative DAT:
1. Neutralization of AHG—inadequately washed RBCs
2. Improper pH of the saline used for washing RBCs (Optimal pH-7.0–7.2)
3. Interruption to testing—bound IgG may dissociate from cells

False positive DAT:
1. Agglutinated RBCs before washing (invalidates results of DAT)
2. Contaminants in the equipment (dust particles may cause false agglutination)
3. Over centrifugation—may cause failure of cells to disperse

2. **Indirect** (Coombs) **antiglobulin test (IAT)** detects the immunoglobulin (IgG) antibody or C3 complement (usually C3d) in the patient's serum. **O Rh +ve normal red cells and antiglobulin serum are added to the patient's serum.** Agglutination of RBCs indicates the presence of antibodies in the patient's serum and the test is reported as positive for an indirect antiglobulin test.

Treatment
- **Corticosteroids** (e.g., prednisolone in doses of 1 mg/kg daily) are effective in about 80% of patients. Initially for the first 2–4 weeks, prednisolone 60 mg daily is given, followed by gradual tapering of the dose. When a dose of 20–30 mg daily achieves a persistent remission (indicated by the stable Hb level and decreasing reticulocyte count), it is recommended to give prednisone on alternate day. Patients with rapid hemolysis may require intravenous methylprednisolone at a dose of 250–1,000 mg/day for 1–3 days.
- **Avoid blood transfusion** as far as possible, because autoantibodies may cause difficulty in crossmatching the blood.
- Danazol can be used along with prednisone as first-line therapy allowing for a shorter duration of prednisone therapy.
- **Splenectomy** may be necessary.
  - If there is no response to corticosteroids
  - If the remission is not maintained when the dose of prednisolone is reduced
  - If there is requirement of the equivalent of more than 10–15 mg prednisone per day to maintain an acceptable hemoglobin level

- **Intravenous immunoglobulin** may also be used as a temporary measure before performing splenectomy for patients refractory to conventional therapy with corticosteroids.
- **Rituximab** is a monoclonal antibody directed against the CD20 antigen expressed on B lymphocytes.
  - **Use:** Useful in refractory cases and also in secondary type of warm AIHA.
  - **Adverse effects:** Hypotension, fever, chills, rigors, hypertension, bronchospasm, pulmonary infiltrates, acute respiratory distress syndrome, myocardial infarction, cardiogenic shock
  - **Contraindication:** Untreated hepatitis B infection
- **Other immunosuppressive drugs** (e.g., azathioprine, cyclophosphamide, and cyclosporine) may be effective when there is no response to steroids, rituximab, and splenectomy.

Cold Agglutinin Autoimmune Hemolytic Anemia

Q. Discuss cold hemagglutinin disease (CHAD) in brief.

- It is less common than the warm antibody type and is caused by so-called **cold agglutinins**.
- These antibodies bind to red cell antigens at low temperatures (4–18°C), i.e., avidity of red cell to antibody increases as the temperature falls.
- The antibodies are of IgM type.
- Clinically, it presents acrocyanosis (i.e., blue color of the fingertips, toes, nose, and ear lobes) after exposure to cold. Patients are advised to avoid exposure to cold.

Investigations

- **Red cells** agglutinate in the cold or at room temperature.
- **Direct antiglobulin test** is positive with complement alone.
- **Monoclonal IgM antibodies.**

Treatment

Rituximab (anti-CD20) is successful in some cases. It does not respond to steroids alkylating agents and splenectomy.

Paroxysmal Cold Hemoglobinuria

Q. Write a short essay/note on paroxysmal cold hemoglobinuria.

- Paroxysmal cold hemoglobinuria (PCH) is a rare condition which often follows common childhood viral infections (e.g., measles, mumps, and chickenpox).
- The autoantibodies are IgG type and bind to red cells at low temperatures and fix the complement. These are autoantibodies directed against the P antigen system on red cells.
- Since complement cascade functions more efficiently at 37°C, upon warming, complement gets activated resulting in intravascular hemolysis and hemoglobinuria.
- **Donath–Landsteiner test:** Hemolysis is demonstrated in vitro by incubating the patient's red cells and serum at 4°C and then warming it to 37°C.
- Hemolysis is usually transient and found mostly in children. Supportive transfusions of warmed blood may be required.
- DAT is usually negative.

Anemias Due to Blood Loss

Q. Write a short essay/note on anemias due to blood loss.

Anemias due to blood loss can be acute or chronic. Blood loss causes anemia by two main mechanisms:

1. By the direct loss of RBCs
2. Continuous blood loss gradually depletes the iron stores resulting in iron deficiency.

Anemias Due to Acute Blood Loss

A healthy adult can lose about 500 mL of whole blood without any untoward effect (e.g., blood donation). Acute blood loss (hemorrhage) causes loss of intravascular volume over a short period and if massive it can lead to hypovolemic shock and death. The clinical features of acute blood loss anemia depend on:

- Rate of hemorrhage
- Nature of the bleeding (external or internal).

Clinical features

After the sudden loss of a large volume of blood over a short period, three clinical/pathophysiologic stages can be identified.

1. **Stage 1:** The dominant feature is hypovolemia during which the patient appears pale, cold, and sweating. The pulse rate is raised and blood pressure is maintained. The earliest signs, especially with internal bleeding, are postural hypotension and tachycardia. An ordinary blood count will not show anemia because the hemoglobin concentration is not affected.
2. **Stage 2:** During this stage, the body will shift fluid from the extravascular to the intravascular compartment, producing hemodilution. Thus, the hypovolemia gradually converts to anemia. Anemia appears in 24–36 hours.
3. **Stage 3:**
   - If bleeding stops, anemia gets corrected in a few weeks, provided body iron supply is normal.
   - If bleeding continues, compensatory mechanisms fail and hypovolemic shock develops and results in death.

Investigations

- Hemoglobin and hematocrit:
  - Normal in early stages (before hemodilution)
  - Reduced in 24–36 hours due to hemodilution
- Peripheral smear shows normocytic normochromic anemia and polychromasia (due to increased reticulocytes). A transient leukoerythroblastic blood picture may be seen in very early stages.

Anemia Due to Chronic Blood Loss

In chronic blood loss, compensatory mechanisms replenish the plasma volume and red cell loss. It produces anemia when the rate of blood loss exceeds the regenerative capacity of the bone marrow or when iron reserves are depleted and results in iron deficiency anemia.

Treatment

Replacement of blood loss by transfusion of whole blood or packed red cells.

Anemia of Chronic Disease

Q. Write a short essay/note on anemia of chronic disease.

It is one of the most common types of anemia in developing countries, occurring in patients with chronic infections (also known as anemia of inflammation).

Causes

It occurs in a wide variety of chronic diseases.

- **Chronic infections:** Infective endocarditis, tuberculosis, osteomyelitis
- **Chronic immune disorders:** Crohn's disease, rheumatoid arthritis, systemic lupus erythematosus (SLE)
- **Associated with malignant tumors** (e.g., carcinoma of lung and breast)

Term anemia of chronic disease is not usually applied to anemias associated with renal, hepatic, or endocrine disorders.

Pathogenesis

- **Impaired iron utilization:** Chronic inflammatory diseases activate macrophages to secrete cytokines such as interleukin-6 (IL-6) and tumor necrosis factor (TNF). There is decreased transfer of iron from the storage pool to bone erythroid precursors.
- **Decreased erythropoietin (EPO) production and response:** They result in inadequate proliferation of progenitors.
- **Decreased RBC survival** is due to extracorpuscular defect.

Investigations

- Peripheral smear mainly shows normocytic normochromic red cells.
- **Increased storage iron** in the marrow and revealed by Prussian blue staining
- **Raised serum ferritin** because of the inflammatory process
- **Reduced total iron-binding capacity (TIBC)**

- **Reduced serum iron**
- Reduced transferrin levels
- Normal serum soluble transferrin receptor level.

Management
- Treat the underlying disorder.
- Recombinant erythropoietin therapy may be tried if the anemia is not corrected after treatment of the underlying disorder.

Aplastic Anemia

Q. PA17.1 **Enumerate the etiology, pathogenesis and findings in aplastic anemia.**

Definition

Aplastic anemia is characterized by pancytopenia (anemia, neutropenia, and thrombocytopenia) with hypocellular (aplasia) bone marrow (less than 30% cellularity), and there are no leukemic or other abnormal cells in the peripheral blood or bone marrow.

Causes

See **Table 9.18.**

TABLE 9.18: Common causes of aplastic anemia.

Inherited	
Fanconi anemia Diamond-Blackfan anemia Telomerase defects	
Acquired	
Idiopathic Acquired defects in stem cell Immune-mediated	
Secondary	
➢ ***Chemical agents*** – **Dose related:** Cytotoxic drugs (alkylating agents, antimetabolites), Benzene, Inorganic arsenicals, chloramphenicol – **Idiosyncratic:** Chloramphenicol, phenylbutazone, penicillamine, carbamazepine, gold salts, organic arsenicals, methyl-phenyl-ethyl hydantoin ➢ ***Physical Agents***: Whole-body irradiation	➢ ***Viral Infections*** ➢ Hepatitis (unknown type) – Epstein–Barr virus infections – Cytomegalovirus infections – Herpes zoster (Varicella zoster) – HIV

Clinical Features

It is insidious in onset and the initial presenting feature depends on which cell line is predominantly affected.

- **Anemia:** Causes progressive weakness, lassitude, fatigability, pallor, and dyspnea
- **Neutropenia:** Presents as frequent infections (mucocutaneous bacterial) or fatal infections. These include sore throat, oral and pharyngeal ulcers, fever with chills and sweating, chronic skin infections, recurrent respiratory infections, pneumonia, and septicemia.
- **Thrombocytopenia:** Results in bleeding manifestations in the form of petechiae, bruises, and ecchymoses. These include: bleeding into skin (ecchymoses, petechiae), epistaxis, menorrhagia, bleeding from gums and GI tract, retinal hemorrhage, and cerebral hemorrhage. Bleeding is often the predominant initial presentation with bruising, with minimal trauma or blood blisters in the mouth.

Physical findings: These include ecchymoses, bleeding gums, and epistaxis. Mouth infections are common. Lymphadenopathy and **hepatosplenomegaly** are **rare**. In the presence of splenomegaly, the diagnosis of aplastic anemia should not be made.

Aplastic anemia may coexist or progress to clonal disorders, such as paroxysmal nocturnal hemoglobinuria (PNH), myelodysplastic syndrome (MDS), or acute myeloid leukemia.

Fanconi's Anemia

- Fanconi's anemia is inherited as an autosomal recessive disorder.
- It is associated with skeletal (short stature), renal (ectopic kidney, horse-shoe kidney), and central nervous system (hydrocephalus) abnormalities. It usually presents between 5 and 10 years of age. Progressive pancytopenia, predisposition to hematologic malignancies (MDS < acute myeloid leukemia), and solid tumors (squamous cell carcinomas of head and neck and anogenital region) are found.

Investigations

Diagnosis is made with: (1) pancytopenia, (2) absence of reticulocytes, and (3) hypocellular or aplastic bone marrow with increased fat spaces.

- **Hemoglobin is decreased.**
- **PCV is decreased.**
- **Reticulocytopenia** (varies from 0.5 to 1%) is a characteristic feature.
- **Peripheral blood** shows pancytopenia.
- **Bone marrow study:** Marked hypocellularity with replacement of more than 70% of the marrow cells by fat. Hematopoiesis: Paucity of all erythroid, myeloid, and megakaryocytic precursors. Initial stages may show focal areas of hematopoiesis. Lymphocytes and plasma cells are prominent. Bone marrow iron stores are usually increased.
- **Serum iron and transferrin saturation:** Increased
- **Ferrokinetic studies:** Delayed clearance of radioactive iron from the blood and increased uptake by the liver.

Severe aplastic anemia

The presence of two of the following four features is needed to diagnose severe aplasia: (1) neutrophil count of $<0.5 \times 10^9/L$, (2) platelet count of $<20 \times 10^9/L$, (3) reticulocyte count of $<40 \times 10^9/L$, and (4) marrow cellularity <25%.

Treatment/Management

Removal of the causative factor/agent wherever possible (refer to causes of aplastic anemia in **Table 9.18**).

Providing supportive care while awaiting bone marrow recovery:

- Prevention and treatment of infections
- Treatment of hemorrhage
- Treatment of anemia by red cell transfusion
- **Growth factors:** Granulocyte colony-stimulating factor (G-CSF), Thrombopoietin (TPO) receptor agonists

Severe aplastic anemia

- **Bone marrow (stem cell) transplantation** is the treatment of choice for patients under 40 years of age who have an HLA-identical sibling donor. Patients over the age of 40 years have a high risk of graft-versus-host disease.
- **Immunosuppressive therapy** is used for patients without HLA-matched siblings and those above 40 years of age.
  - Eltrombopag, horse ATG, cyclosporine, and prednisone in combination produce a hematological response rate of 60–80%. These agents destroy activated suppressor cells.
  - Androgens (e.g., oxymetholone) are sometimes useful in patients not responding to immunosuppression and those with moderately severe aplastic anemia.
  - Steroids have little role in severe aplastic anemia but are useful for serum sickness induced by ALG. However, steroids used in children with congenital pure red cell aplasia (Diamond-Blackfan syndrome) and in some adults with pure red cell aplasia are associated with a thymoma.
  - Anti-IL-2 receptor antibody (daclizumab) and arsenic trioxide (ATO) plus cyclosporine have been tried.

Acquired pure red cell aplasia (PRCA) may develop for unknown reasons, but more commonly it develops in association with specific types of malignancy, infection, or drugs. Most commonly, acquired PRCA develops as a complication of a neoplastic process such as a thymoma B- or T-cell chronic lymphocytic leukemia, non-Hodgkin's lymphoma, or an autoimmune disorder such as rheumatoid arthritis or SLE.

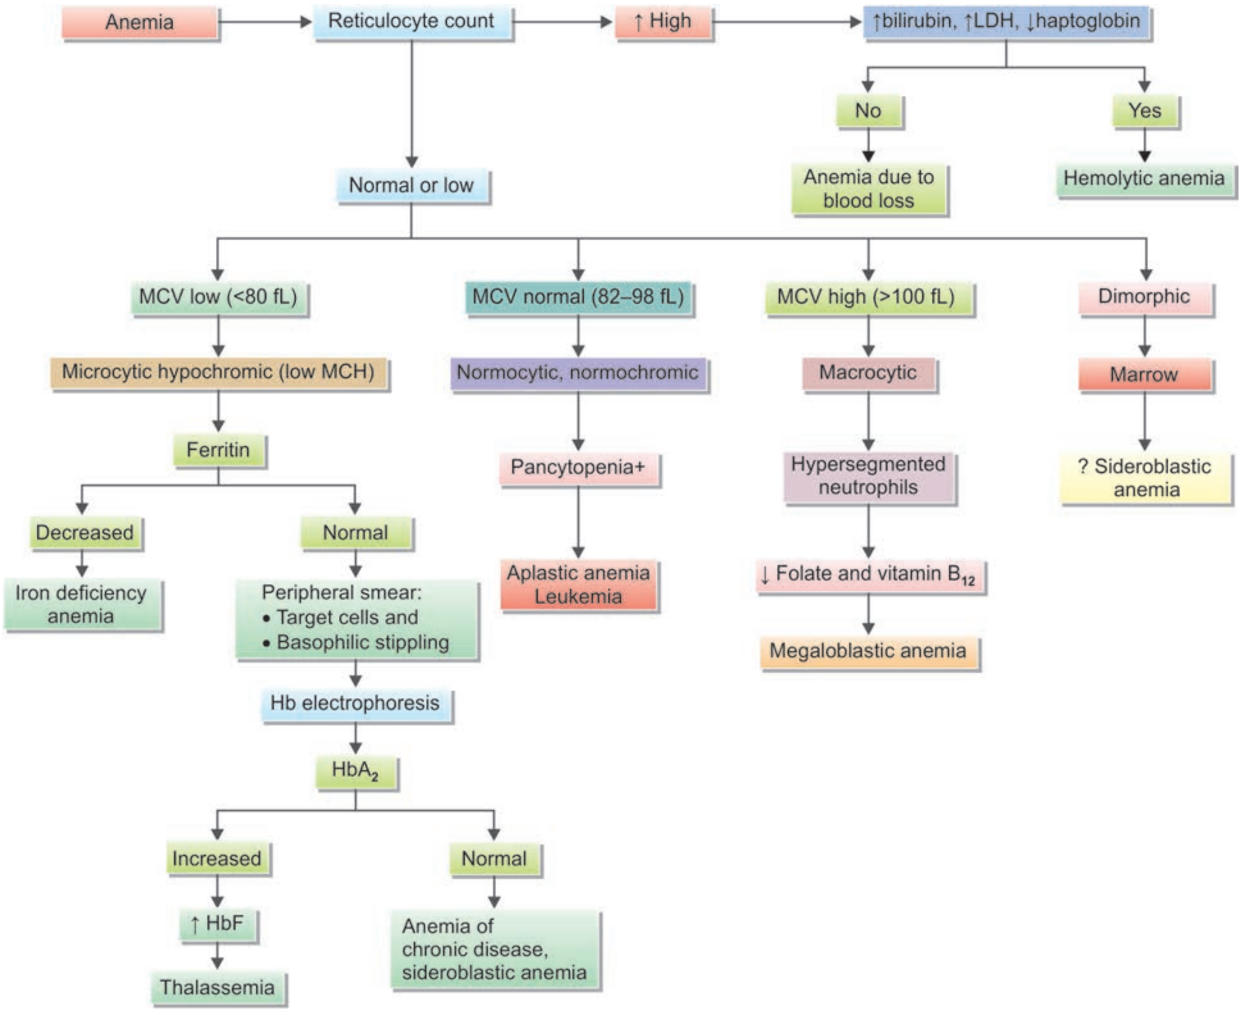
Investigation of a case of anemia is presented in **Flowchart 9.2.**

Pancytopenia

Q. Write a short essay/note on the causes of pancytopenia.

Definition: Combination of anemia, leukopenia, and thrombocytopenia.

FLOWCHART 9.2: Investigation of a case of anemia.



Anemia
Reticulocyte count
↑ High
↑bilirubin, ↑LDH, ↓haptoglobin
No
Yes
Anemia due to blood loss
Hemolytic anemia
Normal or low
MCV low (<80 fL)
MCV normal (82–98 fL)
MCV high (>100 fL)

Thalassemia
Anemia of chronic disease, sideroblastic anemia

Causes of Pancytopenia (Table 9.19)

TABLE 9.19: Causes of pancytopenia.

- **Decreased bone marrow function**
  - Aplastic anemia
    - Idiopathic
    - Secondary
    - Inherited
- Myelodysplastic syndromes (MDS)
- Bone marrow infiltration with:
  - Leukemia (e.g., Hairy cell leukemia)
  - Lymphoma
  - Myeloma
    - Tumors (carcinoma)
    - Granulomatous diseases (e.g., disseminated tuberculosis, sarcoidosis)
  - Nutritional deficiencies:
    - **Megaloblastic anemia** (vitamin B_{12} and folic acid deficiency)
  - Paroxysmal nocturnal hemoglobinuria
  - Myelofibrosis (rare)
  - Others: Hemophagocytic syndrome, overwhelming sepsis, systemic lupus erythematosus
  - Drugs
- **Increased peripheral destruction**
  - Hypersplenism

DISORDERS OF WHITE BLOOD CELL

Non-Neoplastic Disorders of WBC Leukocytosis

Q. Write a short note on leukocytosis.

An increase in the **total** number of **leukocytes** in the blood **more than 11,000/mm³** (11 × 10^9/L). It is usually due to increase in the neutrophils but may also be due to increased lymphocytes (or rarely monocytes and eosinophils).

Causes: Common causes of leukocytosis are shown in **Box 9.10**.

Box 9.10: Common causes of leukocytosis.

- Infections:
  - Bacterial
  - Viral infections (e.g., infectious mononucleosis)
- Leukemia:
  - Acute
  - Chronic: Chronic lymphocytic leukemia and chronic myeloid leukemia
- Leukemoid reactions
- Physiological:
  - Pregnancy
  - Exercise

Leukopenia

Total leukocyte count is less than 4,000/mm^3 (4 × 10^9/L).

Causes: Common causes of leukopenia are shown in **Box 9.11**.

Neutrophilia

Neutrophilia is an absolute neutrophil count of more than 8,000/mm^3 (8 × 10^9/L). Differential count shows more than 70% neutrophils and is usually accompanied by leukocytosis (15–30 × 10^9/L).

Causes of neutrophilia: Major causes of neutrophilia are shown in **Box 9.12**.

Box 9.11: Common causes of leukopenia.

- Typhoid and paratyphoid
- Anemia
  - Aplastic anemia
  - Megaloblastic anemia
- Hypersplenism
- Drugs including cytotoxic drugs
- Radiation
- Rarely leukemia

Box 9.12: Major causes of neutrophilia.

Pathological:

- Acute bacterial and fungal infections:
  - Localized: Pyogenic microorganisms causing infections, e.g., pneumonias, pyogenic meningitis, cellulitis, diphtheria, abscess, and tonsillitis
  - Generalized: Septicemia, acute rheumatic fever
- Acute inflammatory processes: Inflammatory conditions (acute appendicitis), vasculitis
- Tissue necrosis: Burns, myocardial infarction, gangrene, neoplasms (tumor necrosis)
- Acute stress or hypoxic states: Following hemorrhage, hemolysis and surgery
- Myeloproliferative neoplasms: Chronic myeloid leukemia, polycythemia vera
- Metabolic: Uremia, acidosis, gout
- Miscellaneous: Eclampsia, steroid therapy

Physiological:

- Exercise (shift from marginating pool to circulating pool), newborns, extremes of temperature, pain, emotional stress and during obstetric labor

Neutropenia and Agranulocytosis

Q. Write a short note on neutropenia/agranulocytosis and its causes. Mention the drugs that cause agranulocytosis.

Reduction in the absolute neutrophil count (total WBC × % segmented neutrophils and band forms) below **1.5 × 10^9/L (1,500/mm^3).** ***Agranulocytosis*** is the term used when the neutrophil count decreases below 0.5 × 10^9/L. These patients are highly susceptible to bacterial and fungal infections.

Etiology

The causes of neutropenia are presented in **Table 9.20**.

Treatment of neutropenia/agranulocytosis (*refer* Oncology Chapter).

TABLE 9.20: Causes of neutropenia.

1. **Inadequate production:**
   - ➢ ***Suppression of stem cells:*** In these disorders, granulocytopenia represents a component of pancytopenia
     - Aplastic anemia
     - Marrow infiltration
     - Metastatic tumors
     - Granulomatous disorders
   - ➢ ***Suppression of committed granulocytic precursors:***
     - Drugs and chemicals (e.g., sulfonamides, analgesics, arsenicals)
     - Ionizing radiation
   - ➢ ***Diseases associated with ineffective hematopoiesis:***
     - Megaloblastic anemias: Vitamin B_{12} or folate deficiency
     - Myelodysplastic syndromes
   - ➢ ***Congenital:*** Kostmann syndrome (rare)
   - ➢ ***Severe infections:***
     - Bacterial (e.g., typhoid, paratyphoid, septicemia)
     - Viral (e.g., influenza, infectious mononucleosis, hepatitis, measles)
     - Rickettsial (e.g., scrub typhus)
     - Protozoal (e.g., malaria, kala-azar)
2. **Increased destruction of neutrophils:**
   - ➢ ***Immunologically mediated destruction:***
     - Idiopathic
     - Secondary
       - ◆ Drugs (Chemotherapeutic drugs, carbimazole, propylthiouracil, phenothiazines, antibiotics, naproxen)
       - ◆ Autoimmune disorders: For example, systemic lupus erythematosus
   - ➢ **Splenic sequestration** may be associated with pancytopenia.
3. **Shift from the circulating pool to marginating pool:** Hemodialysis and cardiopulmonary bypass
4. **Idiopathic:**
   - ➢ Hodgkin and non-Hodgkin lymphoma
   - ➢ Chronic lymphocytic leukemia
   - ➢ Viral infections (HIV, hepatitis)
   - ➢ Cyclic neutropenia

TABLE 9.21: Causes of eosinophilia.

- **Allergic/atopic conditions**
  - Asthma
  - Urticaria
  - Hay fever
  - Drug reactions
  - Allergic rhinitis
- **Parasitic/helminthic infestations (with tissue invasion)**
  - Roundworm infestation
  - Hookworm infestation
  - Filariasis
- **Fungal infections** (e.g., coccidioidomycosis)
- **Skin diseases**
  - Dermatitis (eczema)
  - Pemphigus
  - Scabies
  - Dermatitis herpetiformis
- **Hematological diseases**
  - Chronic myeloid leukemia
  - Polycythemia
  - Hodgkin lymphoma
  - Acute myelomonocytic leukemia
  - Eosinophilic leukemia
- **Miscellaneous**
  - Tropical eosinophilia
  - Pulmonary eosinophilia
  - *Löffler syndrome*
  - Hypereosinophilic syndrome
  - Eosinophilic granuloma
  - Drugs: Sulfonamides, aspirin, penicillins, cephalosporins, allopurinol, carbamazepine

TABLE 9.22: Causes of lymphocytosis.

- **Acute infections**
  - Viral infections
  - Infectious mononucleosis, mumps, measles, chickenpox, infectious hepatitis
  - Toxoplasmosis
- **Chronic infections/inflammatory diseases**
  - Tuberculosis
  - Syphilis
  - Brucellosis
  - Inflammatory bowel disease: Crohn's disease and ulcerative colitis
- **Hematologic malignancies**
  - Acute lymphoblastic leukemia
  - Chronic lymphocytic leukemia
  - Non-Hodgkin lymphoma with spillover
  - Adult T-cell leukemia/lymphoma
  - Hairy cell leukemia

Eosinophilia

Q. Define eosinophilia and mention the causes of eosinophilia.

Eosinophilia is an absolute **eosinophil count of more than $450/\text{mm}^3$** (0.45×10^9/L). Causes of eosinophilia are presented in **Table 9.21**.

Lymphocytosis

Q. Write a short note on lymphocytosis and its causes.

Lymphocytosis is lymphocyte count more than $4{,}000/\text{mm}^3$ (4×10^9/L) in adults and more than $8{,}000/\text{mm}^3$ (8×10^9/L) in a child. The common causes of lymphocytosis are given in **Table 9.22**.

Basophils

Conditions associated with alterations in numbers of blood basophils are presented in **Table 9.23**.

TABLE 9.23: Conditions associated with alterations in numbers of blood basophils.

Decreased numbers (basopenia)

- Hereditary absence of basophils (very rare)
- Elevated levels of glucocorticoids
- Hyperthyroidism or treatment with thyroid hormones
- Ovulation
- Hypersensitivity reactions
- Leukocytosis (in association with diverse disorders)

Increased numbers (basophilia)

- Allergy or inflammation
  - Ulcerative colitis
  - Drug, food, inhalant hypersensitivity
  - Erythroderma, urticaria
  - Juvenile rheumatoid arthritis
  - Infection
    - Chickenpox
    - Influenza
    - Smallpox
    - Tuberculosis
  - Iron deficiency
- Endocrinopathy
  - Diabetes mellitus
  - Estrogen administration
  - Hypothyroidism (myxedema)
- Exposure to ionizing radiation
- Neoplasia
  - Basophilic leukemia
  - Myeloproliferative neoplasms (especially chronic myelogenous leukemia; also polycythemia vera, primary myelofibrosis, essential thrombocythemia)
  - Carcinoma

ACUTE LEUKEMIAS

Q. Define leukemia.

Definition

Leukemia is defined as a group of malignant stem cell neoplasms characterized by:

- Failure of cell maturation and proliferating of leukocyte precursors (blast/immature cells) which fill the bone marrow
- Abnormal numbers and forms of immature white blood cells which ultimately spill over into the peripheral blood.

Classification of Leukemias

Q. Write short essay/note on classification of leukemias.

1. **General/traditional classification:** According to the light microscopic appearance of the cell and the speed of evolution **(Table 9.24)**
2. **Revised French–American–British (FAB) classification of acute leukemias (Table 9.25)**
    - According to FAB, the marrow should show a blast count of 30% or more.
    - It includes parameters which affect morphology, cytochemistry, immunophenotyping, cytogenetics, and molecular genetics.
3. **WHO classification (2022) of acute myeloid (Table 9.26) and lymphoid leukemia (Table 9.27)**.
    - WHO classification of acute leukemia incorporates parameters, namely morphology, cytochemistry, cytogenetic, molecular genetics (which are related to prognosis), and clinical features.
    - The number of blasts necessary for the diagnosis is ≥10% in bone marrow or peripheral blood (except AML with t(9;22) which has a blast cut off of ≥20%) when compared to 30% in FAB classification.

TABLE 9.24: Traditional classification of leukemia.

Acute	***Chronic***
Acute myeloblastic/myelocytic leukemia (AML)	Chronic myeloid leukemia (CML)
Acute lymphoblastic/lymphocytic leukemia (ALL)	Chronic lymphocytic leukemia (CLL)

TABLE 9.25: Revised FAB classification of acute leukemias.

Type of AML	*Type of ALL*
M0: Minimally differentiated AML M1: AML without differentiation M2: AML with maturation M3: Acute promyelocytic leukemia M4: Acute myelomonocytic leukemia M5: Acute monocytic leukemia M6: Acute erythroleukemia (Di Guglielmo's disease) M7: Acute megakaryocytic leukemia	L1: Small cells with homogeneous nuclear chromatin and scanty cytoplasm L2: Large, heterogeneous cells with variable amount of cytoplasm L3: Large, homogeneous cells with prominent nucleoli, abundant, and deeply basophilic vacuolated cytoplasm

TABLE 9.26: WHO classification (2016) of acute myeloid leukemia and related precursor neoplasms.

WHO 2022 classification of AML
➢ **Myeloid neoplasm post cytotoxic therapy**
➢ **AML with defining genetic abnormalities**
– Acute promyelocytic leukemia with *PML::RARA fusion*
– AML with *RUNX1::RUNX1T1 fusion*
– AML with *CBFB::MYH11 fusion*
– AML with *DEK-NUP214 fusion*
– AML with *RBM15::MRTFA fusion*
– AML with *BCR::ABL1 fusion*
– AML with *KMT2A rearrangement*
– AML with *MECOM rearrangement*
– AML with *NUP98 rerrangement*
– AML with *NPM1 mutation*
– AMl with *CEBPA mutation*
– AML with myelodysplasia-related
– AML with other defined genetic alterations
➢ **AML defined by differentiation**
– AML with minimal differention
– AML without maturation
– AML with maturation
– Acute basophilic leukemia
– Acute myelomonocytic leukemia
– Acute monocytic leukemia
– Acute erythroid leukemia
– Acute megakaryoblastic leukemia

(AML: Acute myeloid leukemia; PML: Progressive multifocal leukoencephalopathy; RARA: Retinoic acid receptor alpha; WHO: World Health organization)

TABLE 9.27: WHO classification (2022) of acute lymphoblastic leukemia.

Precursor B-cell neoplasms
B-cell lymphoblastic leukemia/lymphomas
➢ B-cell lymphoblastic leukemia/lymphoma, NOS
➢ B-cell lymphoblastic leukemia/lymphoma with high hyperdiploidy
➢ B-cell lymphoblastic leukemia/lymphoma with hypodiploidy
➢ B-cell lymphoblastic leukemia/lymphoma with iAMP21
➢ B-cell lymphoblastic leukemia/lymphoma with BCR::ABL1 fusion
➢ B-cell lymphoblastic leukemia/lymphoma with BCR::ABL1-like features
➢ B-cell lymphoblastic leukemia/lymphoma with KMT2A rearrangement
➢ B-cell lymphoblastic leukemia/lymphoma with ETV6::RUNX1 fusion
➢ B-cell lymphoblastic leukemia/lymphoma with ETV6::RUNX1-like features
➢ B-cell lymphoblastic leukemia/lymphoma with TCF3::PBX1 fusion
➢ B-cell lymphoblastic leukemia/lymphoma with IGH::JL3 fusion
➢ B-cell lymphoblastic leukemia/lymphoma with TCF3::HLF fusion
➢ B-cell lymphoblastic leukemia/lymphoma with other defined genetic abnormalities
Precursor T-cell neoplasms
T-cell lymphoblastic leukemia/lymphomas
➢ Early T-cell precursor lymphoblastic leukemia, NOS
➢ Early T-precursor lymphoblastic leukemia/lymphoma

(WHO: World Health Organization; NOS: Not otherwise specified)

Etiology of Leukemias

Q. Discuss the etiology of leukemias.

Risk Factors

In the majority of acute leukemias, the cause is not known. Numerous risk factors may cause mutations in the genes involved in regulating cell proliferation and differentiation.

These genes include oncogenes and tumor suppressor genes. Sophisticated molecular techniques such as fluorescent in situ hybridization (FISH) and gene array technology have led to the understanding of leukemia at the molecular level.

Environmental factors

- **Ionizing radiation:** Ionizing radiation and X-rays are associated with increased risk of leukemias. The evidence for this association is:
  - **Atomic bombing:** Survivors of atomic bomb explosions in Hiroshima and Nagasaki, who had high incidence of AML and CML (chronic myeloid leukemia).
  - **Therapeutic radiation:** Increased risk of AML (secondary leukemia) in patients with malignancies/neoplasms treated by radiation.
  - **X-ray exposure to fetus during pregnancy**.
- **Drugs:** Drugs can cause secondary hematopoietic neoplasms.
  - Secondary AML can develop after exposure to chemotherapy drugs.
  - Alkylating agents such as cyclophosphamide can lead to AML that develops after a median duration of 5–7 years, is usually preceded by myelodysplastic syndrome, and is associated with chromosome 5 or 7 abnormalities.
  - Topoisomerase inhibitors such as anthracyclines lead to AML after a median duration of 1–3 years and are associated with MLL gene abnormalities.
- **Chemicals:** Benzene used in paint industry, plastic glues, etc. It causes chromosomal abnormalities resulting in a higher incidence of acute leukemia, myelodysplastic syndrome, and aplastic anemia.
- **Retroviruses: Human T-cell leukemia virus (**HTLV-1) is associated with adult T-cell leukemia/lymphoma.
- **Immunological:** Immune deficiency states (e.g., hypogammaglobulinemia).

Genetic disorders

A few genetic disorders may be associated with acute leukemias, e.g., Down's syndrome (ALL or AML), Fanconi's anemia (AML), ataxia telangiectasia (ALL, NHL), and Klinefelter syndrome.

Acquired disorders

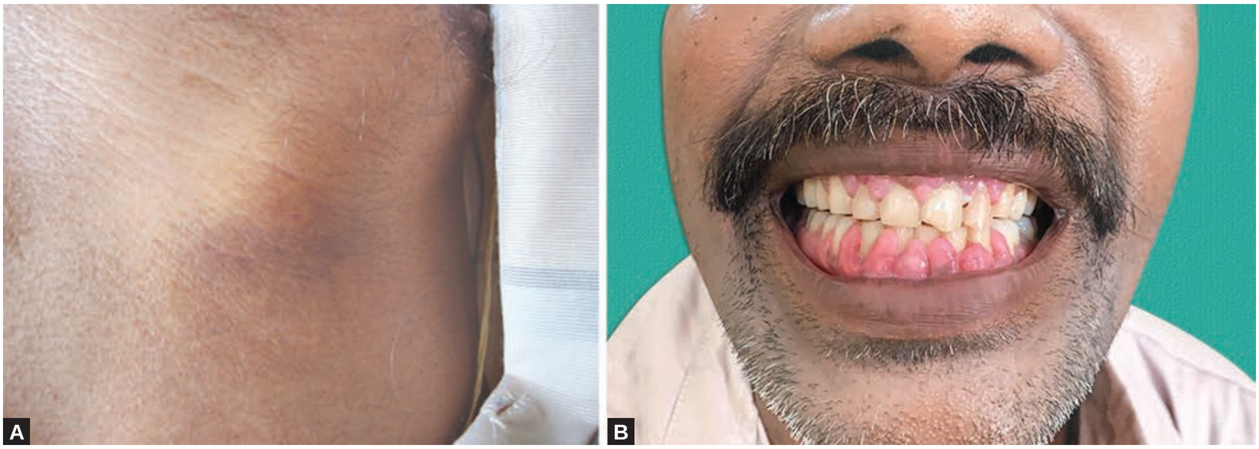
- Acquired stem cell disorders such as PNH and aplastic anemia may transform into acute leukemia.
- **Myelodysplastic syndrome (MDS):** AML may develop de novo or secondary to MDS.

Clinical Features

Q. Discuss the clinical features, investigations, diagnosis, and management of acute leukemias.

Q. PE29.8 Discuss the etiology, clinical presentation and management of acute lymphoblastic leukemia in children.

- Though ALL and AML are distinct (immunophenotypically and genotypically), they usually have similar clinical features. A patient usually presents with nonspecific "flu-like" symptoms.
- Majority of patients with acute leukemia, regardless of subtype, present with symptoms arising from:
  - **Bone marrow failure:** It is due to replacement of normal marrow hematopoietic cells by leukemic blast cells.
    - **Anemia:** It causes shortness of breath on effort, excessive tiredness/fatigue, and weakness.
    - **Neutropenia**
      - It results in life-threatening infections by bacteria or opportunistic fungi, *Pseudomonas* and commensals. Fever is due to septicemia.
      - The infection may develop in the oral cavity, skin, lungs, kidneys, urinary bladder, and colon. The common presentations include respiratory infections (pneumonia), cellulitis, or sepsis.
    - **Thrombocytopenia**
      - It presents as bleeding manifestations in the form of petechiae, atraumatic ecchymosis, gum bleeding, epistaxis, urinary tract, and fundal hemorrhages.
      - Intracranial bleeding is a serious and fatal complication, usually associated with headache, fundal hemorrhages, and focal neurological deficits.
    - Marrow expansion and infiltration of the subperiosteum cause:
      - Bone pain (more common in ALL) and sternal tenderness.
  - **Leukostasis:** Stasis of blood flow may develop when the blast count is above 50,000/mm^3.
    - Cerebral leukostasis may cause headache, confusion, and visual disturbances.
    - Pulmonary leukostasis can cause dyspnea atrest, tachypnea, chest pain, pulmonary infarction, and acute respiratory distress syndrome.
  - **Coagulopathy:** Both disseminated intravascular coagulation (DIC) and primary fibrinolysis may lead to hemorrhagic diathesis. DIC is observed in AML-M3 (promyelocytic leukemia).



FIGS. 9.29A AND B: Chloroma and gingival hyperplasia.

- **Extramedullary leukemic infiltration:**
  - Gingival hypertrophy and infiltration of skin (leukemia cutis/chloroma) **(Figs. 9.29A and B)**
- Hepatosplenomegaly
- Generalized lymphadenopathy
- Leukemic meningitis is rare. It presents as headache and nausea. As the disease progresses, papilledema, cranial nerve palsies, seizures, and altered consciousness develop. CSF characteristically shows leukemic blast cells, elevated proteins, and reduced glucose levels.
- **Chloromas** are localized, solid, soft-tissue tumor masses known as myeloblastomas, granulocytic sarcomas, or chloromas.
  - **Metabolic abnormalities:** Hyperuricemia, elevated serum liver transaminases, and serum LDH are found in patients with acute leukemia.

Investigations

Q. Write short essay on laboratory diagnosis of acute myeloid leukemia. What are Auer rods?

Confirmation of Diagnosis

- **Blood count**
  - Hemoglobin is low.
  - Total leukocyte count: Markedly raised, but usually less than 100×10^9/L (range 1×10^9/L to 500×10^9/L). Leukopenia is common in AML.
  - Platelet count: It is markedly decreased.
- **Peripheral blood smear**
  - It shows numerous **blast cells (Figs. 9.30 and 9.31)**, and types of blasts can be identified morphologically and confirmed with immunophenotyping.
  - **Auer rods** are seen as rod-shaped red inclusion in the cytoplasm of myeloblast.
  - It shows severe normochromic anemia.
- **Bone marrow aspirate:** Hypercellular with reduced erythropoiesis and reduced megakaryocytes. **Blast cells >20%** (often approaching 100%) and type of blast is confirmed by flow cytometry, immunophenotyping (FISH), cytogenetic, and molecular genetics.

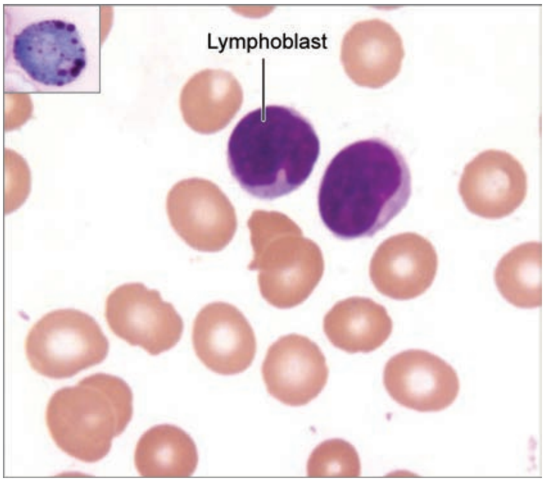


FIG. 9.30: Peripheral blood smear in acute lymphoblastic leukemia showing lymphoblasts. Inset shows lymphoblast with block positivity with PAS stain.

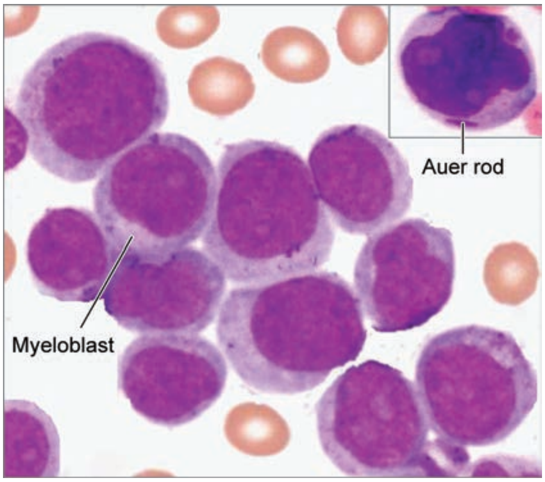

FIG. 9.31: Peripheral smear in AML with myeloblasts. Inset shows myeloblast with Auer rod.

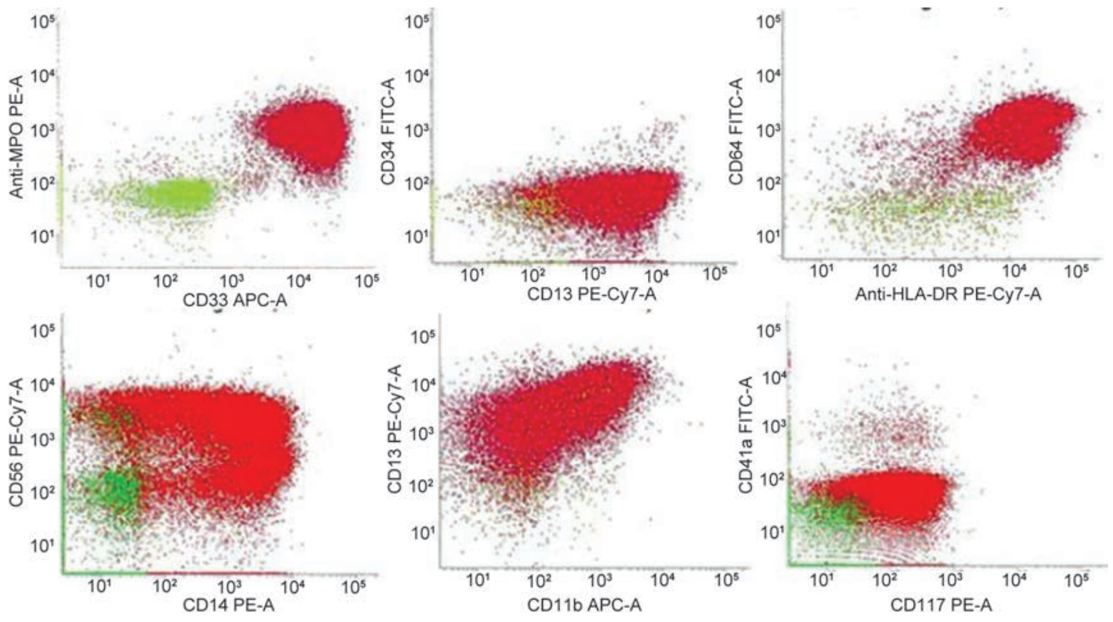
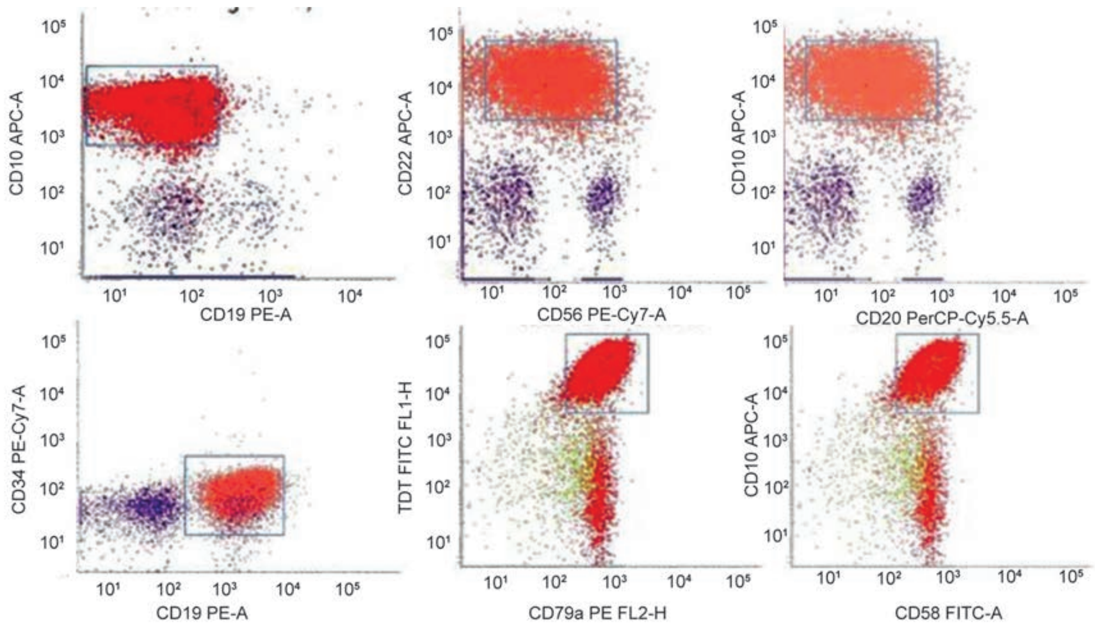
Flow cytometry

Q. Write short note on flow cytometry in leukemias.

- Flow cytometric immunophenotyping is useful in diagnosing the lineage in acute leukemia by the expression of lineage-specific CD markers.
- Flow cytometry allows the detection of 1 leukemic cell among 10,000 normal cells **(0.01%)**.
- Common antibodies used in flow cytometric immunophenotyping of acute leukemia are: stem cell/hematopoietic precursors (CD34, HLA-DR, terminal deoxynucleotidyl transferase/TdT), myeloid markers (cMPO, CD13, CD33, CD117, CD15), monocytic markers (CD64, CD14, CD11b,CD11c, lysozyme), erythroid (CD71, CD235a), megakaryocytic (CD41, CD61, CD36), B lymphoid markers (CD19, CD10, CD20, CD22, cCD79a), T lymphoid markers (CD3, CD5, CD7, CD1a,CD2, CD4, CD8), and natural killer (NK) cells (CD56).



Pattern seen in AML



Flow cytometry pattern seen in ALL

  - Therapeutic application—targeted therapy (e.g., Rituximab if anti-CD20 positive, Alemtuzumab if anti-CD52 positive), purging malignant cells from autografts before transplantation
- **Chest X-ray:** Mediastinal widening is often seen in T-lymphoblastic leukemia.
- **CSF examination:** This is done to rule out occult CNS involvement.

For Planning Therapy

- **Biochemical parameters:** Serum uric acid levels, liver function tests, renal function tests, coagulation studies, serum LDH, etc.
- **Cardiac function:** ECG and direct tests of left ventricular function (e.g., echocardiogram or MUGA scan)

Q. Discuss the management of acute leukemias.

Management

Principles of management

At initial presentation, acute leukemia may be:

- Probably curable (childhood acute lymphoblastic leukemia)
- Possibly curable (de novo low-risk AML)
- Probably incurable (AML with adverse cytogenetic features in the elderly, secondary AML, recurrent acute leukemia).

Type of therapy

- **Palliative therapy:** It is directed toward symptomatic benefit by means of medications and transfusions with or without chemotherapy.
- **Curative intent:** The goal is to cure the patient and involves chemotherapy +/- stem cell transplant.

Active therapy

The first and major decision to be taken is whether to give specific therapy or supportive therapy.

Supportive care/therapy

It forms the basis of treatment for both curative and palliative therapy.

- Treatment of anemia with repeated transfusion of packed red cells to avoid symptoms of anemia (hemoglobin >10 g/dL)
- Prevention or control of bleeding due to thrombocytopenia with platelet transfusions
- Treatment of infection:
  - *Prophylactically:* Education about handwashing and isolation facilities. Use of selected antibiotics and antifungal agents, barrier nursing
  - *Therapeutically:* Management of fever by identifying the microorganism and giving appropriate antimicrobial treatment in bacterial, fungal, protozoal, and viral infections
- Continuous monitoring of liver, kidney, and hemostatic functions
- Maintenance of fluid and electrolyte balance: In patients receiving chemotherapy, rapid lysis of leukemic cells may produce tumor lysis syndrome characterized by hyperuricemia, hyperkalemia, hypocalcemia, and hyperphosphatemia leading to renal injury, arrythmias, and seizures and is potentially life-threatening. It can be prevented by close attention to hydration, urine alkalinization, and prophylactic allopurinol before starting chemotherapy.
- Treatment of hyperleukocytosis: Reduction in leukocyte counts can be achieved by using chemotherapy or hydroxyurea, and leukapheresis (removal of circulating cells and re-infusion of leukocyte-poor plasma).
- Psychological support.

Bone marrow transplantation has to be considered in the following conditions:

1. Acute myeloblastic leukemia (Intermediate and poor risk) in first remission in patients below 60 years of age
2. Acute lymphoblastic leukemia (ALL) (high risk) in first, second, or subsequent remission

Specific therapy

The specific therapy is intended to return the peripheral blood and bone marrow to normal (complete remission—CR).

The survival outcomes of acute leukemia are variable; they could be in excess of 90% in situations such as APML and childhood ALL to as low as 10% in recurrent acute leukemia and high-risk AML.

Q. Discuss the management of acute lymphocytic leukemias. Enumerate the drugs used in acute lymphocytic leukemia.

Acute lymphocytic leukemia

Specific therapy **(Table 9.28)** involves:

- **Remission induction** with combination chemotherapy
  - Goal of induction therapy: To induce morphologic remission and to restore normal hematopoiesis in the bone marrow with less than 5% blasts.
  - Remission induction consists of combination chemotherapy including vincristine, prednisolone (dexamethasone), asparaginase (crisantaspase), and usually an anthracycline antibiotic, e.g., doxorubicin. It induces complete morphologic response within 4–6 weeks.

TABLE 9.28: Treatment for acute lymphoblastic leukaemia (ALL).

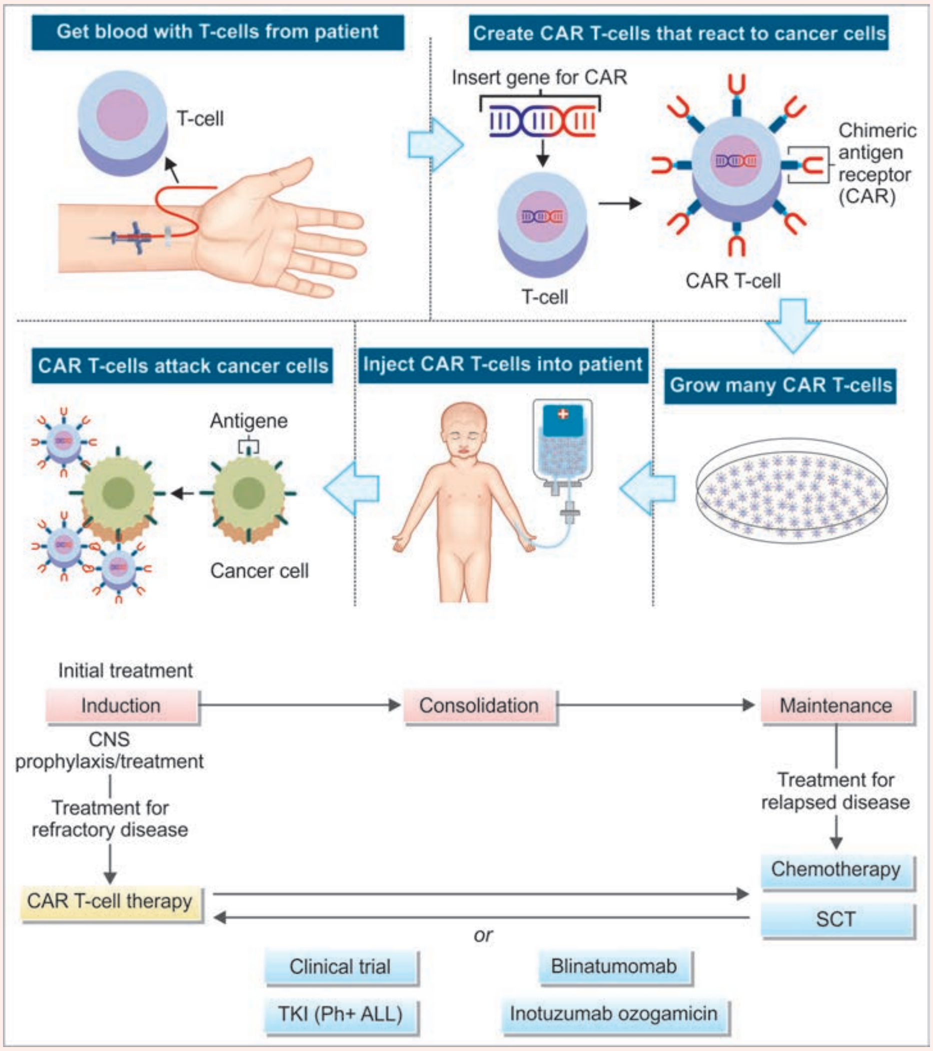
Induction therapy	
t(9;22)/BCR-ABL1 negative ALL ➢ Weekly administration of vincristine and daunorubicin for 3–4 weeks, daily corticosteroids (prednisone, prednisolone, or dexamethasone), and pegylated L-asparaginase	t(9;22)/BCR-ABL1 positive ALL ➢ Tyrosine kinase inhibitors (TKI) such as imatinib or dasatinib added to the above chemotherapy regimen Patients with trisomy 21 ➢ High-dose methotrexate
CNS preventive therapy	
➢ Triple intrathecal chemotherapy (cytarabine/methotrexate/hydrocortisone) or 1,800 cGy cranial radiation	
Postremission therapy	
Consolidation regimen containing ➢ Cytarabine, methotrexate ➢ Anthracyclines (daunorubicin, doxorubicin)	➢ Alkylating agents (cyclophosphamide, ifosfamide) ➢ Epipodophyllotoxins (etoposide, etopophosphamide) **Allogeneic hematopoietic cell transplantation**
Maintenance therapy	
➢ Daily oral 6-mercaptopurine, weekly methotrexate with periodic vincristine, prednisone, and intrathecal therapy for 2 years approximately	

Q. Discuss CAR T-cell therapy.

CAR T-cell therapy is an important new option for pediatric and young adult patients.

- Tisagenlecleucel is an autologous anti-CD19 **chimeric antigen receptor (CAR) T-cell therapy** recently approved by the US Food and Drug Administration for patients with refractory leukemia or those with second or later relapse.
- In this treatment strategy, a patient's own T cells are transduced to express an anti-CD19 CAR that, when reintroduced into the patient, directs specific binding and killing of CD19+ B cells.

CAR T-cell Therapy



Get blood with T-cells from patient
T-cell
Create CAR T-cells that react to cancer cells
Insert gene for CAR
T-cell
Chimeric antigen receptor (CAR)
CAR T-cell
Grow many CAR T-cells
Inject CAR T-cells into patient
CAR T-cells attack cancer cells
Antigene
Cancer cell
Initial treatment
Induction
Consolidation
Maintenance
CNS prophylaxis/treatment
Treatment for refractory disease
Treatment for relapsed disease
Chemotherapy
SCT
CAR T-cell therapy
or
Clinical trial
Blinatumomab
TKI (Ph+ ALL)
Inotuzumab ozogamicin

- **CNS preventive therapy** that includes administration of high-dose systemic therapy and CNS-directed treatment
  - **Aim:** To eliminate disease in the CNS and to reduce systemic minimal residual leukemic burden
  - **CNS-directed therapy:** Triple intrathecal chemotherapy (cytarabine/methotrexate/hydrocortisone) or 1,800 cGy cranial radiation
- **Postremission therapy,** similar to induction phase, reduces chances of relapse.
- **Remission maintenance** to prevent relapse and affect cure. It involves administering drugs for 2 years or more and consists of daily 6-mercaptopurine and weekly methotrexate.

Q. Discuss the management of acute myeloid leukemias.

Acute myeloid leukemia (Table 9.29)

Initial therapeutic goal is to quickly induce complete remission (CR) and further therapy to prolong survival and achieve cure. Curative therapy is given to the majority of adults below the age of 60 years (without any significant comorbidity).

Specific therapy (Table 9.29) of the newly diagnosed patient with AML is usually divided into two phases: (1) induction and (2) consolidation phase (postremission) therapy.

- **Induction chemotherapy:**
  - Moderately intensive combination chemotherapy that includes an anthracycline (e.g., daunorubicin or idarubicin) and cytosine arabinoside (cytarabine) ± etoposide.
  - "High risk"patients (include patients <70 years with high-risk karyotype) may only be treated with curative intent if an HLA-identified sibling is available for stem cell transplantation.
- **Consolidation or postremission therapy:** For patients achieving remission with induction therapy in young patients (<60 years) consists of 3 to 4 cycles of high-dose cytosine arabinoside.
  - Low-risk patients in AML; patients with t(8;21) or inv(16) (i.e., low risk karyotype) do not benefit from allogeneic stem cell transplantation during their first complete remission.
  - Patients with high-risk karyotypes should have stem cell transplantation because they respond poorly to conventional chemotherapy.

Acute promyelocytic leukemia (M3)

- It is an uncommon variant of AML associated with severe coagulation complications.
- It has favorable prognosis.
- Induction therapy is with **all-trans-retinoic acid** and anthracyclines or a combination of ATRA with arsenic trioxide.
- Allogeneic transplantation: It is necessary if the leukemia is not eliminated at the molecular level, only in relapsed/refractory cases.
- In relapsed cases, arsenic trioxide (induces apoptosis via activation of the caspase cascade) has been also found to be effective.

Alternative chemotherapy

- It is used to curb excessive leukocyte proliferation and not for achieving remission.
- Hydroxyurea up to 4 g daily and L asparaginase 10,000 units are used to reduce leukocyte count without inducing bone marrow failure.

TABLE 9.29: Treatment for AML (acute myeloid leukemia).

Initial treatment for AML

Intensive remission induction (7+3 therapy)

- ➢ Continuous infusion of cytarabine (100 or 200 mg/m^2 daily for 7 days) together with daunorubicin (by short infusion or bolus for the first 3 days)
- ➢ Alternative remission induction approaches Gemtuzumab ozogamicin (GO) 6 mg/m^2 on day 1, and 3 mg/m^2 on day 8, and continue treatment with GO for up to eight monthly cycles
- ➢ Other regimens
  - FLAG (fludarabine, cytarabine, G-CSF), FLAG-IDA (idarubicin), MITO-FLAG (mitoxantrone), and FLAMSA (amsacrine)
  - CLAG (cladribine, cytarabine, G-CSF)
  - Vorinostat (histone deacetylase inhibitor) plus idarubicin and cytarabine
  - Bortezomib, daunorubicin, and cytarabine
  - Lenalidomide

Postremission management

- ➢ Consolidation chemotherapy—cytarabine + daunorubicin or with gemtuzumab ozogamicin
- ➢ Hematopoietic cell transplantation (HCT)
- ➢ Maintenance therapy—with gemtuzumab ozogamicin Or Midostaurin

Relapsed or resistant AML

Gemtuzumab ozogamicin, midostaurin, enasidenib, lower intensity treatments (e.g., azacitidine, decitabine), or palliative management

Poor Prognostic Factors in AML and ALL (Table 9.30)

TABLE 9.30: Poor prognostic factors in AML and ALL.

Features	***Acute myeloblastic leukemia (AML)***	***Acute lymphoblastic leukemia (ALL)***
Age	>60 years	<1 year or >9 years
TLC	>1,00,000/mm^3	>30,000 in B-ALL and >100,000 in T-ALL
French–American–British (FAB) type	M_0, M_5, M_6, M_7	L_3 type
Chromosomal abnormality	High-risk karyotype [t(6;9), inv(3)]	Hypodiploidy (<45 chromosomes), pH positive ALL t(1:19) MLL rearranged
Other features	➢ Secondary cause present ➢ Following myelodysplastic syndrome (MDS) ➢ Relapsed disease ➢ Secondary leukemia ➢ Extramedullary disease	➢ Male gender ➢ Mediastinal mass ➢ CNS involvement ➢ pH-like ALL

Differences Between Acute Lymphoblastic Leukemia and Acute Myeloblastic Leukemia (Table 9.31)

Q. How do you differentiate acute lymphoblastic leukemia from acute myeloblastic leukemia?

TABLE 9.31: Differences between acute lymphoblastic leukemia and acute myeloblastic leukemia.

Clinical features	***Acute lymphoblastic leukemia***	***Acute myelogenous leukemia***
Age	Predominantly children	Predominantly adults
Coagulopathy (DIC)	Absent	Seen in M_3
Gingival hypertrophy and dermal infiltrate (chloromas)	Absent	Seen in M_4 and M_5
Hepatosplenomegaly	In majority (50–75%)	Frequent
Lymphadenopathy	More common	Less common
Leukemic meningitis	More common	Less common
Testicular involvement	In 10–20%	–
Eye involvement	More common	Less common
Investigations		
Type of leukemic blasts	Lymphoblasts (10–15 μm) are smaller than myeloblasts, with a thin rim of agranular cytoplasm and round or convoluted nucleus	Myeloblasts (12–20 μm) are larger than lymphoblasts, with discrete nuclear chromatin and multiple nucleoli
Auer rods (in the cytoplasm)	Absent	Present in 10–20% (diagnostic)
Terminal deoxynucleotidyl transferase (TdT) in leukemic blasts	In more than 90%	Rare
Cytochemistry		
Myeloperoxidase	–ve	+ve
Sudan Black B	–ve	+ve
Nonspecific esterase	–ve	+ve in M_4 and M_5
Periodic acid Schiff (PAS)	+ve in >50% of cells (Block positivity)	Negative

Subleukemic Leukemia/Aleukemic Leukemia

Q. Write short note on subleukemic leukemia.

- In acute leukemia, the immature neoplastic leukemic "blast" cells proliferate and accumulate but fail to mature. The blasts diffusely replace the normal bone marrow, and a variable number of these accumulate in the peripheral blood.
- Acute leukemia should be diagnosed when the blast cells constitute more than 20% of the nucleated cells in the marrow (normally blast cells < 5%) with an increase in total leukocyte count.
- **Subleukemic/aleukemic leukemia** is characterized by a total leukocyte count which is normal or lower than 4×10^9/L, and peripheral blood shows very few abnormal blasts. It is observed in a small percentage of patients with acute leukemia.
- Diagnosis is confirmed from the bone marrow examination which shows replacement by leukemic cells.

Leukemoid Reaction

Q. Write short note on leukemoid reaction (including its definition).

- Extreme neutrophilia is sometimes associated with the presence of immature white cells and is called leukemoid reaction.
- A **leukemoid reaction** is a benign leukocytic proliferation characterized by a total leukocyte count of more than 50×10^9/L with many immature white cells (such as metamyelocytes, myelocytes, and promyelocytes and even a few myeloblasts) in the peripheral smear.
- Leukemoid reaction is the response of the normal healthy bone marrow to various stresses.
- **Causes:** Include infections (including tuberculosis), acute hemorrhage, hematological and nonhematological malignancies, and various toxic states.
- Bone marrow is normal with accelerated leukopoiesis.
- LAP source is increased.
- Philadelphia chromosome is negative.
- There is no absolute eosinophilia or basophilia (versus CML).

- Treatment of underlying disorder corrects the blood picture.
- Types of leukemoid reactions are listed in **Box 9.13**.
- It should be differentiated from chronic myelocytic leukemia **(Table 9.32)**.

Box 9.13: Types of leukemoid reactions.

- Myeloid
- Lymphoid

TABLE 9.32: Differences between leukemoid reaction and chronic myeloid leukemia.

Clinical features	***Leukemoid reaction***	***Chronic myeloid leukemia***
Peripheral blood findings	Features of causative disease	Splenomegaly, lymphadenopathy, and bone pain are common
WBC series		
Total WBC count	Moderately increased, rarely exceeds 50×10^9/L	Markedly increased and usually exceeds 50×10^9/L
Differential leukocyte count	➢ Shift to the left with few immature forms ➢ Toxic granulation seen	➢ Shift to the left with numerous immature forms ➢ Myelocyte and neutrophil peak
Eosinophilia and basophilia	Variable	Present
Leukocyte alkaline phosphatase (LAP)	Increased	Decreased
RBC series		
Anemia	Usually minimal or absent	Severe and progressive
Platelets		
Number	Variable	Normal or increased
Extramedullary myeloid tumors	Absent	Present
Philadelphia chromosome	Absent	Present

Hairy Cell Leukemia

Q. Discuss the clinical features, investigations, and management of hairy cell leukemia.

Clinical Features

- Hairy cell leukemia **(HCL)** is an uncommon chronic malignant disorder of mature B-cells with characteristic fine cytoplasmic projections.
- The term **hairy cell leukemia** is derived from the appearance of fine hairlike cell membrane projections on the leukemic cells, under the phase-contrast microscope.
- Hairy cell leukemia affects middle-aged to elderly men, with a male-to-female ratio of 5:1.
- Clinical features are mainly due to leukemic infiltration of bone marrow, liver, and spleen.
  - **Massive splenomegaly** is the most common finding, hepatomegaly is less common, and lymphadenopathy is distinctly rare.
  - **Pancytopenia** is due to marrow failure and splenic sequestration and is found in more than 50% of cases.
  - **Infections:** About one-third of patients present with infections, especially with atypical mycobacteria, which may be due to monocytopenia. Infections are the most common cause of death.
  - Risk of secondary malignancies such as Hodgkin's lymphoma, non-Hodgkin's lymphoma, and thyroid cancer is there.

Investigations

- **Total leukocyte count:** It is normal or low. Majority of patients have pancytopenia.
- **Peripheral smear:** It shows the characteristic hairy cells. These are the medium-sized malignant B lymphocytes with filamentous hairy structures on the surface of the cell. They have a reniform nucleus and abundant pale blue cytoplasm. Cytochemically, these hairy cells stain positively for **tartrate-resistant acid phosphatase (TRAP)**.
- **Bone marrow:** Aspirate yields a dry tap and biopsy shows fibrosis with infiltration by mononuclear cells and hairy cells (fired-egg or honeycomb appearance).
- LAP score is very high. Flow cytometry reveals CD11c, 25, 103, 123 positivity.

Treatment

- Indications for treatment: If the patient develops
  - Cytopenia
  - Symptomatic splenomegaly
  - Constitutional symptoms (e.g., fever, night sweats, and fatigue).
- Treatment of infections with antibiotics.
- Chemotherapy: The purine analogs 2-chloroadenosine acetate (2-CDA) (cladribine) and pentostatin are highly effective with just one cycle of treatment. Rituximab is used in patients who do not respond to the above drugs. Pentostatin, interferon alfa, and splenectomy are other treatment options available.
- Contraindicated drugs: Corticosteroids and myelotoxic drugs

Prognosis: Follows an indolent course and prognosis is excellent.

CHRONIC MYELOID LEUKEMIA

Q. Define chronic myeloid leukemia. Write a short note on Philadelphia chromosome and its significance.

Definition: Chronic myeloid leukemia (CML) is one of the **myeloproliferative neoplasms** (MPN) of **pluripotent hematopoietic stem cell** characterized by **overproduction** of cells of the **myeloid series** (results in marked splenomegaly and leukocytosis) and the presence of the Philadelphia chromosome.

Molecular Pathogenesis

- **Philadelphia (Ph) chromosome**
    - Acquired chromosomal abnormality of **hematopoietic stem cells**
    - **Balanced reciprocal translocation between the long arms of chromosomes 9 and 22 (t 9,22)** increases the length of chromosome 9 and shortening of 22. The **shortened chromosome 22** is known as Philadelphia chromosome **(Ph)**.
- ***BCR-ABL1* fusion gene**
    - Translocation results in fusion of the breakpoint cluster region (*BCR*) gene on chromosome 22q with the *ABL1* (named after the Abelson murine leukemia virus) gene located on chromosome 9q.
    - It produces a new hybrid oncogene, namely *BCR-ABL1* fusion gene. The products of this gene are oncoproteins which have uncontrolled kinase activity and trigger the excessive proliferation and reduced apoptosis of CML cells.
    - **Significance:** Apart from CML, Philadelphia (Ph) chromosome can be found in ALL (25–30% in adult and 2–10% in pediatric cases) and occasionally in AML. In patients with Ph positive/negative and *BCR-ABL1* positive, the survival rate and therapeutic response are better than those with both Ph- and *BCR-ABL1*-negative patients.

Natural Course of CML

Q. Discuss the natural course and clinical features of chronic myeloid leukemia.

It has three phases:

1. **Chronic stable phase:** Most of the CML are diagnosed in this phase and lasts for about 3–5 years if untreated.
2. **Accelerated phase:** It is more aggressive and lasts for few months.
3. **Blast crisis phase:** It resembles acute (myeloid or lymphoid) leukemia and has poor prognosis.

Parameter	*Chronic phase*	*Accelerated phase*	*Blast crisis*
White blood cells	≥20	↑	↑
BM Blasts MO	<15%	15–20%	20%
Basophils	<20%	20%	–
Platelets	↑ or normal	↓ or ↑	↓
Marrow cellularity	↑	↑	↑
Cytogenetics	Ph+	Ph+	Ph+
BCR-ABL	+	+	+

Clinical Features in Chronic Stable Phase of CML

Q. Discuss the clinical features in chronic stable phase.

- **Age: It usually occurs between 40 and 60 years** of age.
- **Onset: It is insidious.**

Symptoms

Many patients are asymptomatic during the early stage of CML and may be diagnosed during routine peripheral blood examination.

- **Nonspecific symptoms:** Fatigue, weakness, weight loss, anorexia.
- **Symptoms due to massive splenomegaly: Fullness of abdomen** (abdominal distension, postprandial fullness), reflux esophagitis, dyspnea, and dragging discomfort in the left hypochondrium due to splenomegaly (caused by leukemic infiltration and extramedullary hematopoiesis). Splenomegaly is moderate-to-severe and is a characteristic feature in majority (80–90%) of patients.
- **Symptoms of hypermetabolic state:** Due to rapid turnover of cells, it may result in symptoms such as fatigue, weakness, fever, sweating, heat intolerance weight loss, and anorexia.
- **Priapism:** It is painful penile erection due to leukostasis (associated with marked leukocytosis or thrombocytosis).
- Bleeding tendencies occur late in the disease.

Signs

- **Pallor** due to anemia.
- **Splenomegaly:** Moderate to massive, nontender splenomegaly. It is due to leukemia infiltration and extramedullary hematopoiesis. Presence of tender spleen and splenic friction rub indicate splenic infarction.

- Mild **hepatomegaly** as a result of leukemic infiltration may develop in 60–70% of cases.
- **Sternal tenderness and bone pain:** They are due to hypercellularity of marrow and irritation of periosteum.

Investigations

Q. Discuss the investigations/laboratory investigations/diagnosis of chronic myeloid leukemia.

- **Hemoglobin** is usually less than 11 g/dL.
- **Total leukocyte count** is markedly raised, almost always more than 20,000/μL, often exceeding 1,00,000/μL. In untreated patients, the leukocyte count progressively increases.

Peripheral Smear (Fig. 9.32)

- **RBC** shows a moderate degree of **normocytic normochromic anemia**.
- **WBC:**
    - **Shift to left (shift to immaturity)** with granulocytes at all stages of development (neutrophils, metamyelocytes, myelocytes, promyelocytes, and occasional myeloblasts). **Predominant cells** are **neutrophils and myelocytes** in an untreated patient. **Blasts** are usually **less than 10%** of the circulating white blood cells.
    - There is increase in basophils (<20%) and eosinophils.
- **Platelets:** Count may be normal, increased, or decreased. Automated analyzers may give falsely elevated platelet counts due to disruption of granulocytes.

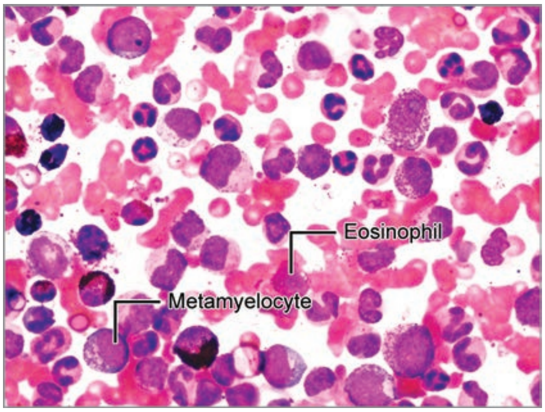


FIG. 9.32: Peripheral blood picture in chronic stable phase of chronic myeloid leukemia.

Bone Marrow Study

- It is markedly hypercellular due to marked hyperplasia of all granulocytic elements.
- About 20–30% of the patients may develop bone marrow fibrosis in late stages.

Philadelphia Chromosome (Ph)

- It is positive in more than 95% of cases, in all three phases. In Ph-negative cases, evidence of translocation can be demonstrated by cytogenetics, reverse transcription-polymerase chain reaction (RT-PCR), and fluorescence *in situ* hybridization (FISH).
- ***BCR-ABL1*** **fusion gene** can be demonstrated in peripheral blood or bone marrow.

Decreased NAP/LAP Score

It is usually below 20 (normal score ranges from 40 to 100) in majority of patients. This is helpful in differentiating CML from leukemoid reaction.

Biochemical Findings

- Serum LDH and uric acid are increased.
- Serum alkaline phosphatase is increased.
- Serum vitamin B_{12} is markedly elevated due to production of binding protein (transcobalamin) by the granulocyte series.
- Marked thrombocytosis may raise serum potassium spuriously as platelets release potassium during clotting.
- Blood sugar may be falsely decreased due to glucose uptake and metabolism by leukocytes.

Q. Write short essay/note on the treatment and complications of chronic myeloid leukemia. Enumerate the drugs used in chemotherapy.

Q. Write short note on Imatinib.

Treatment of CML

Goal of therapy in CML (Table 9.33)

Chemotherapy (Table 9.34)

Tyrosine kinase inhibitors (TKIs)

- ***Imatinib mesylate*** is the first-line treatment for the chronic phase of CML.
- If there is failure of response or progress on imatinib, options include:

  - Second-generation tyrosine kinase inhibitors (such as dasatinib, bosutinib, or nilotinib), allogeneic bone marrow transplantation, or classical cytotoxic drugs such as hydroxycarbamide (hydroxyurea) or interferon-α or melphalan, and busulfan
  - Omacetaxine/homoharringtonine (plant alkaloid).

Imatinib mesylate

- Imatinib mesylate is a tyrosine kinase inhibitor (TKI) which provides targeted therapy, i.e., high specificity blocks the enzymatic action of the *BCR-ABL* fusion, providing a broader therapeutic window with less toxicity.
- In all newly diagnosed CML, imatinib (400 mg/d) is more effective and has replaced IFN-α and cytarabine. It reduces the uncontrolled proliferation of white cells, producing apoptosis of cancer cells.
- In chronic stable disease, it can produce complete hematological response in >95% of cases and complete cytogenetic response (disappearance of the Ph chromosome and *BCR-ABL* transcripts in the blood) in >76% at 18 months of therapy. Imatinib can be continued indefinitely.
- Overexpression of the *BCR-ABL* chimeric gene or genetic alteration can produce resistance to imatinib mesylate.
  - Side effects of imatinib: Nausea, headaches, fluid retention, muscle cramps, diarrhea, skin rash, and myelosuppression (causing cytopenias).

Ponatinib is the only approved TKI capable of inhibiting BCR-ABL with the gatekeeper *T315I kinase domain mutation*, known to be the cause for 20% of resistant or relapsed CML cases.

Recombinant interferon-α

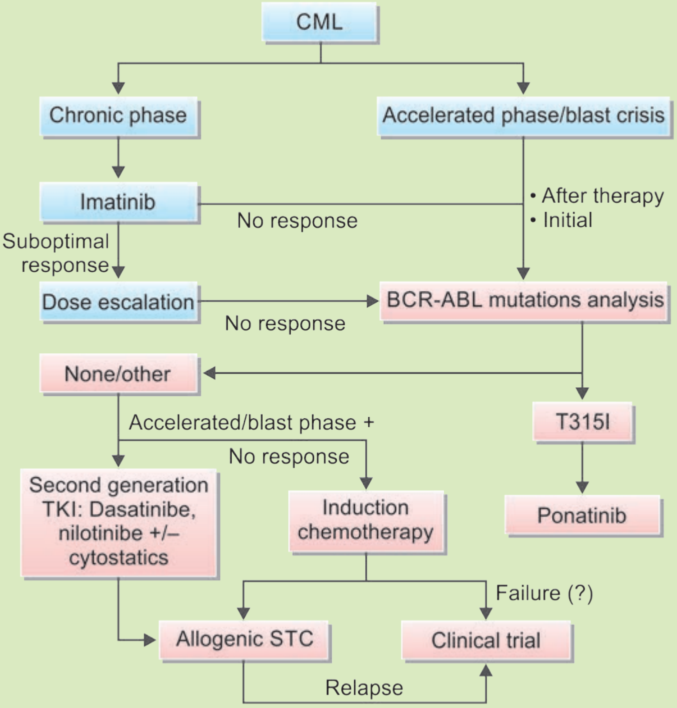
- **Recombinant interferon-α (rINF-α)** was considered first-line treatment before the invention of imatinib.
- It was given alone or combined with the chemotherapy agent cytosine arabinoside, and induced remission and controlled chronic stable phase of CML in about 70% of cases. But it has no role as a single agent in most patients.
- It should be considered in patients not responding to imatinib.
- It is not effective in accelerated phase or blast crisis phase.
- Dosage: 3–9 mega units/day intramuscularly or subcutaneously.
- Actions of rINF-α:
  - Reduces cellularity of the bone marrow.
  - Reduces the number of Philadelphia-positive tumor cells in 20% of patients.
  - Total eradication of Philadelphia chromosome in ~5% of patients.
  - Reduces platelet count when it is very high.
- Side effects: Flu-like syndrome, weight loss, fatigue, nausea, vomiting, and headache

TABLE 9.33: Response criteria in CML.

Level of response	*Definition*
Complete hematologic response	Normal CBC and differential
Minor cytogenetic response	35–90% Ph metaphases
Partial cytogenetic response	1–34% Ph metaphases
Complete cytogenetic response	0% Ph-positive metaphases
Major molecular response	≥3-log reduction of BCR-ABL mRNA
Complete molecular remission	Negativity by qPCR

TABLE 9.34: Drugs used and their dosage for induction and maintenance in chronic stable phase of CML.

Drug	*Induction dose*	*Maintenance dose*
Imatinib mesylate	300–400 mg/day	300–400 mg/day
Hydroxyurea (hydroxycarbamide)	0.5–2.0 g/day	0.5–2.0 g/day
Melphalan	4–12 mg/day	2–4 mg/day
Busulfan	4 mg/day	2–4 mg/day



Hydroxyurea

It is used to reduce white blood cell counts while awaiting confirmation of a suspected diagnosis of CML in a patient with significant leukocytosis (e.g., >100 $\times 10^9$ white cells/L) or in patients with systemic symptoms or with symptomatic splenomegaly.

Splenectomy

It is indicated to relieve the symptoms due to massive splenomegaly and in repeated splenic infarctions.

Stem cell transplantation (SCT)

- Indication:
  - Patients under the age of 60 years who have a suitable donor
  - Those who do not respond to second-line TKI and those who present with accelerated phase or blast crisis

- Best results are obtained if SCT is done in early chronic stable phase and can cure about 70% of cases.
- It can result in permanent disappearance of the Ph-positive clone.
- Disadvantages: These include risk of complications and death due to graft-versus-host disease (GVHD) and opportunistic infections.

Monitoring

- Bone marrow biopsy: It is done at 6-month intervals to determine the cytogenetic response.
- Quantitative RT-PCR (qPCR): It should be done from peripheral blood at 3–6-month intervals once cytogenetic response has been achieved.

Prognostic Scores in CML

- **Sokal score:** Age, spleen size, platelet count, blast cell counts
- **Euro score:** Age, spleen, platelet, blast cell counts, basophil counts, eosinophil counts
- **EUTOS score/Hasford:** Basophils and spleen size.

Accelerated Phase of Chronic Myeloid Leukemia

Chronic myeloid leukemia may transform to a more aggressive blastic phase with or without going through an accelerated phase after 1–5 years of onset. It lasts for a few months.

Features of Accelerated Phase

- Increasing anemia
- Increasing white blood cell count with an increase in circulating immature cells unresponsive to therapy
- Blasts 10–19% are seen in the blood or bone marrow
- Increase in the size of spleen
- Increase in basophil count (<20%)
- Persistent thrombocytopenia or persistent thrombocytosis unresponsive to therapy
- Hydroxyurea is the most effective drug in accelerated phase.

Blast Crisis Phase of Chronic Myeloid Leukemia

- Blast crisis phase of CML represents the transformation of CML into an acute leukemia.
- This final phase lasts for a few weeks to months and has a poor prognosis.
- Blasts constitute 20% or more and may be:
    - Myeloid blast crisis that occurs in 70% when the disease transforms into acute myeloblastic leukemia.
    - Lymphoid blast crisis that occurs in 30% when the disease transforms into acute lymphoblastic leukemia.

Treatment of blast crisis is the same as that for acute myeloblastic or lymphoblastic leukemia. Complications of chronic myelogenous leukemia are enlisted in **Box 9.14**.

Features of Blast Crisis

- Refractory to treatment
- Abrupt increase in the size of spleen
- Bone pain and sternal tenderness
- Anemia and bleeding tendencies
- Generalized lymphadenopathy may appear.
- Peripheral smear and bone marrow showing >30% cells simulating acute leukemia
- Basophils may increase to 20%.
- Thrombocytopenia may result in bleeding episodes.

Box 9.14: Complications of chronic myelogenous leukemia.

- Fatigue due to anemia
- Excess bleeding due to thrombocytopenia
- Bone pain or joint pain due to expansion of bone marrow
- Enlarged spleen
- Vulnerable to infection due to impaired immune system
- Death

CHRONIC LYMPHOCYTIC LEUKEMIA

Q. Discuss the types, clinical features, investigation, clinical staging, and management of chronic lymphocytic leukemia.

Definition

Chronic lymphocytic leukemia (CLL) is a tumor of immature small round lymphocytes characterized by the accumulation of neoplastic mature-looking lymphocytes in the peripheral blood, bone marrow, and lymphoid organs (spleen and lymph nodes).

Types

- **B-cell origin:** More than 95% of the cases of CLL express the pan B-cell markers CD19 and CD20 and also present is the aberrant expression of T-cell antigen CD5 (found only in a small subset of normal B-cells).
- **T-cell origin:** It constitutes less than 5%.

Clinical Features

- It is the most common form of chronic leukemia.
- **Age:** Most of the patients at the time of diagnosis are over 50 years of age.
- **Sex:** It is more common in males than in females with a ratio of 2:1.
- **Asymptomatic:** It is found in about 25% of patients and is detected either because of nonspecific symptoms or routine blood examination for some other diseases.
- **Nonspecific symptoms:** This includes fatigue, loss of weight, and anorexia.
- **Painless generalized lymphadenopathy:** Initially, the cervical lymph nodes are enlarged and in later stages there may be generalized lymphadenopathy. Involved nodes are rubbery, discrete, nontender, small, and mobile.
- **Splenomegaly and hepatomegaly:** Mild degree is observed in very few cases.
- **Presenting symptoms** may be:
  - Slowly developing anemia: Due to immune hemolysis and bone marrow infiltration
  - Recurrent infections: Develop due to hypogammaglobulinemia. *Streptococcus pneumonia*, *Staphylococcus*, and *Haemophilus influenzae* cause most of the infections. Herpes zoster is also common.
  - Bleeding manifestations: They are uncommon.

Transformation

CLL may transform to:

- Prolymphocytic transformation with appearance of "prolymphocytes" in the peripheral blood (>10%).
- Transformation to diffuse large B-cell lymphoma (Richter syndrome).
- **Monoclonal B-cell lymphocytosis (MBL):** WHO criteria for monoclonal B-cell lymphocytosis (MBL) are the presence of monoclonal B-cell populations in the peripheral blood (PB) of up to 5×10^9/L either with the phenotype of chronic lymphocytic leukemia (CLL), atypical CLL, or non-CLL (CD52) B cells in the absence of other lymphomatous features. It has been found that MBL precedes almost all cases of CLL/SLL. In 2016, the WHO subdivided MBL into "low count" MBL (characterized by PB CLL count of $<0.5 \times 10^9$/L) and "high count" MBL. The distinction is important because low-count MBL does not require routine follow-up whereas high-count MBL requires routine/yearly follow-up.

Investigations

- **Hemoglobin:** Usually below 13 g/dL and as the disease progresses, it may decrease below 10 g/dL. This is due to marrow failure, but associated autoimmune hemolysis may also be contributory, when present.
- **Blood counts:**
  - Total leukocyte count is increased and varies from 20×10^9/L to 50×10^9/L.
  - Platelet count may be normal or low.
- **Peripheral blood smear (Fig. 9.33):**
  - Mild-to-moderate normocytic normochromic anemia.
  - Lymphocytosis is the characteristic feature and constitutes more than 50% of the white cells, and absolute lymphocyte count should be more than $5,000 \times 10^9$/L.
  - Lymphocytes are of mature type in majority of the cases.
  - **Smudge cells or basket cells** are disintegrated lymphocytes and are due to the rupture of neoplastic lymphocytes while making the peripheral smear due to its fragile nature.
  - **Platelets:** Normal or reduced in number (autoimmune thrombocytopenia).
- **Bone marrow:** It is involved in all cases of CLL and its infiltration by mature lymphocytes results in hypercellular marrow.
- **Direct Coombs test:** About 15–20% of patients manifest autoimmune hemolytic anemia and have positive direct Coombs test.
- **Lymph node** biopsy shows well-differentiated, small, noncleaved lymphocytes.
- **Immunoglobulins:** They are low or normal.
- Serum folic acid levels are low.

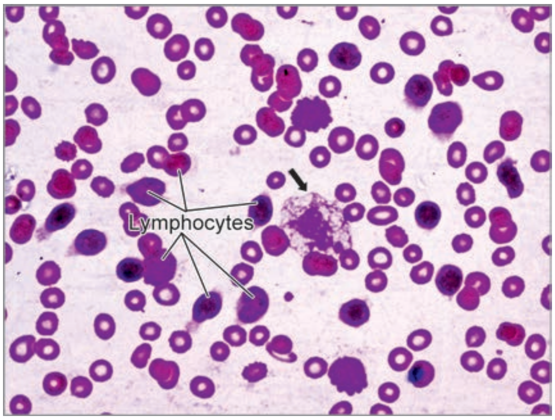


FIG. 9.33: Peripheral blood smear in chronic lymphocytic leukemia showing numerous small lymphocytes and few smudge cells (arrow).

Diagnostic Criteria for Chronic Lymphocytic Leukemia (Table 9.35)

TABLE 9.35: Diagnostic criteria for chronic lymphocytic leukemia.

Lymphocytosis	***Immunophenotype***
Absolute lymphocyte count should be more than 5,000 × 10^9/L	Positive for B-cell surface antigens (CD19, CD20, CD23)
	Aberrant expression of T-cell antigen CD5
Lymphoid cells ≤55% prolymphocytes	Evidence of monoclonality in the form of "light chain restriction"

Clinical Staging

Binet staging and Rai staging of CLL are presented in **Tables 9.36 and 9.37**, respectively.

TABLE 9.36: Binet staging of CLL.

Stage	***Features***	***Survival***
A	No anemia or thrombocytopenia Less than three lymphoid areas enlarged	>10 years
B	No anemia or thrombocytopenia Three or more lymphoid areas enlarged	7 years
C	Anemia (Hb <10 g/dL) and/or thrombocytopenia (<10,000/mm^3) present, regardless of the number of areas of lymphoid enlargement	2 years

TABLE 9.37: Rai staging of CLL.

Stage	***Features***	***Survival***
0	Peripheral blood lymphocytosis alone	>10 years
I	Lymphocytosis with lymphadenopathy	9 years
II	Lymphocytosis with splenomegaly or lymphadenopathy or both	7 years
III	Lymphocytosis with anemia (hemoglobin <11 g/dL) and organomegaly	5 years
IV	Lymphocytosis with anemia, thrombocytopenia, and organomegaly	5 years

Lymphoid enlargement includes cervical, axillary, and inguinal lymph nodes.

Treatment

Absolute indications for treatment: When any of the following features is present:

- Anemia or thrombocytopenia that can be attributed to CLL
- Recurrent fever, extreme fatigue, night sweats, and weight loss
- Bulky or progressive lymphadenopathy; massive or progressive splenomegaly with discomfort
- Autoimmune cytopenias not responsive to corticosteroids
- Symptomatic or functional extranodal involvement (e.g., skin, kidney, lung, spine)
- Progressive disease manifests by doubling of the lymphocyte count in 6 months

Treatment options based on Binet staging (Table 9.38)

Regimen—single-agent fludarabine or combination therapy with fludarabine, cyclophosphamide, and rituximab (FCR)

Chlorambucil: Two regimens

1. Continuous low-dose therapy: 5 mg/day orally
2. Intermittent high-dose therapy (pulse therapy): 0.4 mg/kg for every 2 weeks
   - Complications: Development of myelodysplasia and acute myeloid leukemia

Fludarabine: It is a purine nucleoside analog that is drug of choice in young patients.

- Dose: 25–30 mg/m^2 IV/day for 5 days every 4 weeks
- Complications: Autoimmune hemolytic anemia, opportunistic infections (e.g., *Legionella pneumophila*, *Pneumocystis jiroveci*, *Listeria monocytogenes*, and *Cytomegalovirus*)

Cladribine: It is also a purine nucleoside analog, an alternative to fludarabine. Dose:

- 0.2 mg/kg continuous infusion daily for 7 days every 4 weeks or
- 0.14 mg/kg over 2 hours daily for 5 days every 4 weeks

TABLE 9.38: Treatment options based on Binet and Rai staging.

Stage	***del (17p) or p 53 mut***	***Fitness***	***IGVH***	***Therapy***
Binet A-B, Rai 0-II, inactive disease	Irrelevant	Irrelevant	Irrelevant	None
Active disease or Binet C or Rai III-IV	Yes	Irrelevant	Irrelevant	Ibrutinib or Venetoclax + Obinutumab or Idelalisib + Rituximab (if contraindications for ibrutinib)
	No	Go go	M	FCR (BR above 65 years) or ibrutinib
			U	Ibrutinib or FCR (BR above 65 years)
		Slow go	M	Venetoclax + Obinutuzumab or Chlorambucil + Obinutuzumab or ibrutinib
			U	Venetoclax + Obinutuzumab or ibrutinib or Chlorambucil + Obinutuzumab

CLL first line treatment (updated June 2019)

Pentostatin: It is *a* purine nucleoside analog that can be used instead of fludarabine or cladribine.
Rituximab and alemtuzumab: They are monoclonal antibodies against CD20 and CD52, respectively.

- **Side effects:** Fever, chills, nausea, headache, myalgias

Alkylating agents: Cyclophosphamide, bendamustine.

Newer drugs:

1. Anti CD20 antibodies: Ofatumumab, obinutuzumab
2. BCL2 inhibitor: Venetoclax
3. Bruton tyrosine kinase (BTK) inhibitors: Ibrutinib, acalabrutinib
4. Phosphoinositide 3′-kinase (PI3K) inhibitors: Idelalisib, duvelisib

Chimeric antigen receptor (CAR)—T-cell therapy is an investigational therapy.

MYELOPROLIFERATIVE NEOPLASMS

Q. Define and write short essay/note on myeloproliferative diseases (disorders) or myeloproliferative neoplasms and enumerate myeloproliferative neoplasms.

Definition

Myeloproliferative neoplasms (MPN) (old synonym myeloproliferative disorder/diseases) are clonal hematopoietic stem cell disorders which are characterized by proliferation of one or more of the myeloid lineages (erythroid, granulocytic, megakaryocytic, and mast cells).

It is seen usually in adults with a peak in the 5th to 7th decade. Splenomegaly and hepatomegaly occur commonly due to sequestration of excess hematopoietic cells or proliferation of abnormal hematopoietic cells.

WHO Classification (2016) of Myeloproliferative Neoplasm

WHO classification of MPN has been shown in **Box 9.15**. Mastocytosis is no longer listed under the broad heading of MPN in WHO (2016) classification.

Box 9.15: WHO classification of myeloproliferative neoplasm.

- Chronic myelogenous leukemia, *BCR-ABL1* positive
- Chronic neutrophilic leukemia
- Polycythemia vera (PV)
- Essential thrombocythemia (ET)
- Primary myelofibrosis (PMF)
- Chronic eosinophilic leukemia not otherwise specified
- Myeloproliferative neoplasm, unclassifiable

Polycythemia

Q. Write short essay/note on polycythemia and its classification.

Definition

Polycythemia, or erythrocytosis, refers to an *increase in the number of RBCs above normal* in the circulating blood, usually with a corresponding increase in hemoglobin and PCV level. PCV is a more reliable indicator of polycythemia than is hemoglobin.

Classification and Causes of Polycythemia

Q. Write short note on causes of secondary polycythemia.

Pathophysiological classification of polycythemia has been shown in **Box 9.16.**

Box 9.16: Pathophysiologic classification of polycythemia.

Relative

- Reduced plasma volume with normal red cell mass (hemoconcentration) due to dehydration—low fluid intake, vomiting, diarrhea, sweating, acidosis
- Gaisböck syndrome (spurious polycythemia)

Absolute (increased red cell mass)

Primary (low erythropoietin level)

- Polycythemia vera (erythremia)

Secondary (high erythropoietin level)—erythrocytosis

Compensatory

- Lung disease (e.g., COPD—chronic obstructive pulmonary disease)
- Living in high-altitude
- Cyanotic congenital heart disease (Tetralogy of Fallot, Eisenmenger's complex)
- Chronic carbon monoxide poisoning
- Sleep apnea syndrome
- Smokers

As a consequence of local hypoxia: Renal artery stenosis, end-stage renal disease, hydronephrosis, renal cysts (polycystic kidney disease), postrenal transplant erythrocytosis

Paraneoplastic: Erythropoietin-secreting tumors—renal cell carcinoma, hepatocellular carcinoma, cerebellar hemangioblastoma, uterine leiomyoma, pheochromocytoma

Clinical Features of Polycythemia

- Usually appears insidiously, in late middle age (median age at onset: 60 years).
- Most symptoms are due to the increased red cell mass and hematocrit.

- Plethora and cyanosis due to stagnation and deoxygenation of blood in peripheral vessels are early findings. Headache, dizziness, and visual problems result from vascular disturbances in the brain and retina.
- Increased incidence of thrombotic episodes and bleeding.
- Secondary polycythemia, in addition shows manifestations of the underlying disease.

Polycythemia Vera

Q. Discuss the clinical features, diagnosis, and management of polycythemia vera.

Definition

- Polycythemia vera (PV) is an **acquired myeloproliferative neoplasm** arising from malignant transformation of **hematopoietic stem cell.**
- It is characterized by **trilineage** (erythroid, granulocytic, and megakaryocytic) **hyperplasia** in the bone marrow.
- It leads to **uncontrolled production of red cells, granulocytes and platelets** (panmyelosis) and leads to **erythrocytosis** (polycythemia) and or granulocytosis and thrombocytosis.

Etiology

The etiology of PV is not known. PV is partly due to a failure of apoptosis as a result of deregulation of the *Bcl-x* gene (antiapoptotic gene), in addition a mutation in the tyrosine kinase **JAK 2 V617F** (which causes the substitution of phenylalanine for valine at position 617) has been found; this stimulates low-grade erythropoiesis.

Clinical Features

- Onset is insidious.
- Age and gender: Late middle age (median age at onset is 60 years) and more common in males.
- Features due to increased viscosity and/or decreased cerebral perfusion
    - Plethora (excessive fullness of blood) and deep dusky cyanosis due to stagnation and deoxygenation of blood in peripheral vessels are early findings.
    - Headache, dizziness, vertigo, a sense of fullness in the head, rushing in the ears, visual problems, tinnitus, tiredness, syncope, and even chorea result from vascular disturbances in the brain and retina.
- Severe itching (pruritus) after a hot bath or when the patient is warm is frequent and may be disabling.
- Thrombotic episodes: For example, deep venous thrombosis, myocardial infarction, thrombosis of hepatic veins (producing Budd–Chiari syndrome).
- Bleeding manifestations include epistaxis, bleeding from peptic ulcer, bruising, and intramuscular hemorrhages.
- Peptic ulcer is seen in few patients and is five times more frequent than general population.
- Hyperuricemia: May result in urate stones, gout, and uric acid nephropathy.

Physical findings

- Injection of the conjunctivae, deep red palate, dusky red hands, and retinal venous engorgement.
- Splenomegaly is very common (~70%) and is useful in distinguishing PV from secondary polycythemia.
- Hepatomegaly occurs in ~50%.

Diagnosis

- **Hemoglobin increased ranging from** 14 to 28 g/dL.
- **PCV (hematocrit)** increased to about 60%. However, in many patients, the plasma volume is also increased giving rise to near normal hematocrit. Hence, it is important to determine the red cell mass.
- **Red cell count:** Increased and usually about 6 million/mm^3 (6×10^{12}/L)
- **Increased red cell volume and blood viscosity:** Isotope dilution using the patient's^{51} Cr-tagged red cells (>36 mL/kg in males and 32 mL/kg in females).
- Total white cell count (~70%) and platelet count (~50%) usually increased.
- Absolute basophil count: Increased to >100/μL in majority of patients.
- **Arterial oxygen saturation** (PO_2) is normal and is useful for differentiating it from secondary polycythemia.
- **Erythropoietin (EPO) levels are decreased** in urine and serum, in contrast to secondary polycythemia.
- **Bone marrow** shows either erythroid hyperplasia or hyperplasia of all elements (trilineage hyperplasia) and depletion of iron stores.
- **Leukocyte alkaline phosphatase (LAP):** Increased in majority of patients.

- **Serum vitamin B_{12} and vitamin B_{12}-binding protein** transcobalamin I (TC I) levels: Increased (not routinely measured)
- **Serum uric acid:** Increased indicating increased cell turnover.
- Abnormal liver function tests.
- Janus kinase 2 (JAK2) mutations (e.g., **JAK2V617F mutation**)
    - In ~95% patients with polycythemia vera, and in ~50% of essential thrombocytosis (ET) and primary myelofibrosis.
    - Janus kinases belong to tyrosine kinase family located on chromosome 9.
    - JAK2 is used by the EPO, thrombopoietin, and granulocyte colony stimulating factor (G-CSF) receptors to transmit signals and are involved in hematopoiesis.
    - JAK2 inhibitors are used for managing these patients.

WHO Diagnostic Criteria for Polycythemia Vera

WHO diagnostic criteria for PV have been shown in **Table 9.39**.

Clinical Course

The clinical course tends to proceed as a series of phases.

- Proliferative phase: Erythroid proliferation with increased red cell mass.
- Spent phase: Excessive proliferation of erythroid cells ceases, resulting in stable or decreased erythrocyte mass
- Progression to myelofibrosis
- Acute myelogenous leukemia in 2–5% of cases.

Complications of PV

Complications of PV have been shown in **Box 9.17**.

TABLE 9.39: WHO (2016) diagnostic criteria for polycythemia vera (PV).

Major criteria	***Minor criteria***
Hb >18.5 g/dL (men), >16.5 g/dL (women) **OR** Hb or PCV>99th percentile of reference range **OR** Hb >17 g/dL (men) or >15 g/dL (women) if associated with a documented and sustained increase of >2 g/dL from baseline that cannot explained otherwise **OR** Elevated red cell mass >25% above mean normal predicted value	BM showing hypercellularity with trilineage (panmyelosis) myeloproliferation
	Subnormal serum EPO level
Presence of JAF2V617F (a mutation in JAK2) or similar mutation	Endogenous erythroid colony (EEC) growth
Diagnostic criteria for PV **Either both major criteria +1 minor criterion or first major criterion + 2 minor criteria**	

(BM: Bone marrow; EPO: Erythropoietin)

Box 9.17: Complications of polycythemia vera (PV).

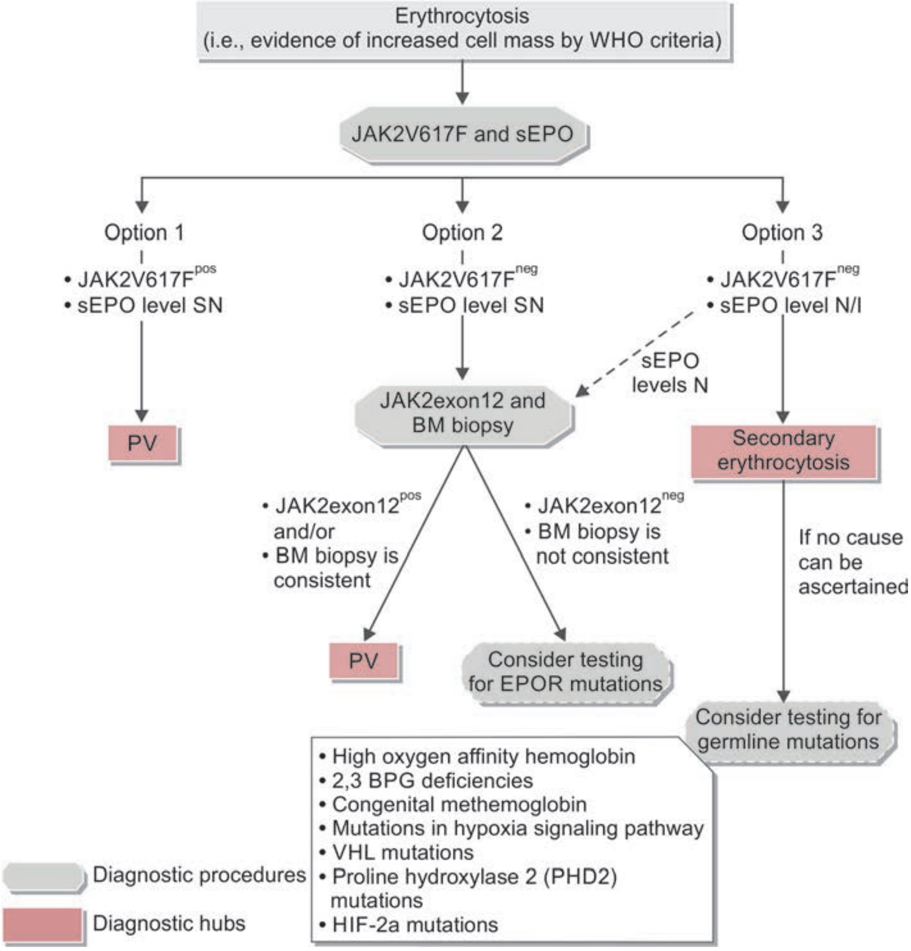
- Thrombotic and bleeding episodes
- Peptic ulcer
- Hyperuricemia (gout)
- Sudden increase in splenic size
- Acute nonlymphocytic leukemia
- Myelofibrosis and myeloid metaplasia
- Erythromelalgia (thrombocytosis, involving the lower extremities with erythema, warmth, and pain and occasionally digital infarction)

Treatment (Fig. 9.34)

PV generally has a very slow course.

Aim of treatment: To maintain a normal blood count, PCV below 0.45 L/L and the platelet count below 400 × 10^9/L and to prevent the complications (mainly thrombosis and hemorrhage).

- **Venesection:** Repeated venesection (phlebotomy) is the treatment of choice and relieves many of the symptoms of PV.
- **Chemotherapy:** Chemotherapy is indicated if the patient is intolerant to venesection, or thrombocytosis occurs, or symptomatic or progressive splenomegaly develops.
    - Continuous or intermittent treatment with **hydroxycarbamide (hydroxyurea)** is the treatment of choice in patients above 40 years. It controls thrombocytosis and generally safer than alkylating agents (e.g., busulfan) and ^{32}P (Phosphorus) which carry an increased risk of acute leukemia
    - In younger patients, interferon-α is used
- **Radioactive ^{32}P:** One dose may give control for up to1½ years, but carries an increased risk to acute leukemia. In elderly patients (>70 years), ^{32}P or low-dose intermittent busulphan may be more convenient
- **Other measures:**
    - Low-dose aspirin: May be used to reduce thrombotic episodes
    - Anagrelide (inhibits platelet aggregation): May be used if thrombotic features develop despite above treatment.
    - Itching should be treated with antihistamines. If do not relieve, hydroxyurea, interferon-α and psoralens with UV light in 'A' range (PUVA) may be helpful
    - Asymptomatic hyperuricemia does not require treatment



Erythrocytosis
(i.e., evidence of increased cell mass by WHO criteria)
JAK2V617F and sEPO
Option 1
• JAK2V617F pos
• sEPO level SN
PV
Option 2
• JAK2V617F neg
• sEPO level SN
JAK2exon12 and BM biopsy
Option 3
• JAK2V617F neg
• sEPO level N/I
sEPO levels N
Secondary erythrocytosis
• JAK2exon12 pos and/or
• BM biopsy is consistent
PV
• JAK2exon12 neg
• BM biopsy is not consistent
Consider testing for EPOR mutations
If no cause can be ascertained
Consider testing for germline mutations
• High oxygen affinity hemoglobin
• 2,3 BPG deficiencies
• Congenital methemoglobin
• Mutations in hypoxia signaling pathway
• VHL mutations
• Proline hydroxylase 2 (PHD2) mutations
• HIF-2a mutations
Diagnostic procedures
Diagnostic hubs

FIG. 9.34: Approach to polycythemia.
(PV: Polycythemia vera)

Q. How will you differentiate primary polycythemia (polycythemia vera) from secondary polycythemia with hypoxia [(e.g., chronic obstructive pulmonary disease (COPD)]?

Differences between polycythemia vera and secondary polycythemia have been shown in **Table 9.40**.

Primary Myelofibrosis

Q. Discuss the clinical features, investigations, and management of primary myelofibrosis (agnogenic myeloid metaplasia, myelofibrosis with myeloid metaplasia).

Definition

Primary myelofibrosis is a clonal MPN characterized by increased fibrosis within the marrow, which replaces hematopoietic cells leading to cytopenias, splenomegaly, and extensive extramedullary hematopoiesis. The extramedullary hematopoiesis is seen in the spleen, liver and at times in lymph nodes, kidneys, and adrenals.

- It can arise from PV or ET.

TABLE 9.40: Differences between polycythemia vera and secondary polycythemia.

Feature	***Polycythemia vera***	***Secondary polycythemia***
Oxygen saturation	Normal	Low
EPO (erythropoietin) levels	Decreased	Increased
Blood counts		
➢ Total white cell count	Increased	Normal
➢ Absolute basophil count	Increased	Normal
➢ Platelet count	Increased	Normal
Leukocyte alkaline phosphatase (LAP)	Raised	Normal
Vitamin B_{12} levels	Increased	Normal
Bone marrow	Trilineage (panhyperplasia)	Erythroid hyperplasia
Splenomegaly	Present	Absent

Clinical Features

- Usually found above 60 years of age.
- A significant number of cases develop acute myeloid leukemia.

Symptoms

- Symptoms due to progressive anemia: Fatigue, weakness, and anorexia.
- Symptoms due to massive splenomegaly: Abdominal distension, postprandial fullness, reflux esophagitis, dyspnea, and dragging discomfort in the left hypochondrium.
- Symptoms resulting from hypermetabolic state: Fever, fatigue, weight loss, night sweats, and heat intolerance.
- Bleeding tendencies due to thrombocytopenia develops at late stages.
- Death usually occurs due to portal hypertension and infections.
- Median survival is about 5 years.

Signs

- Massive splenomegaly and hepatomegaly.
- Anemia, lymphadenopathy, bleeding manifestations, ascites, cardiac failure, and jaundice.
- Hyperuricemia and secondary gout due to a high rate of cell turnover.
- Extramedullary hematopoiesis: May produce paraspinal masses with spinal cord compression, ascites, and effusions (pleural and pericardial).

Investigations

- Hemoglobin level: Normal in the early stages, but markedly reduced in the late stages.
- Total leukocyte count: Normal/increased (early stages)/decreased (late stages).
- Platelet count: Increased in early stages and decreased in the late stages.
- Peripheral smear:
  - **RBC series**
    - Moderate-to-severe degree of normochromic normocytic anemia accompanied by **leukoerythroblastic blood picture** (precursors of granulocytes and nucleated RBCs being present simultaneously).
    - **Many tear drop-shaped red cells** (dacryocytes) probably due to damage in the fibrotic marrow.
    - Basophilic stippling.
  - **Giant platelets** with vacuoles.
- **Bone marrow:** The peripheral smear findings are not specific and bone marrow biopsy is diagnostic.
  - Cellularity: Early stages (cellular phase), it is often hypercellular and in later stages (hypocellular phase), it becomes hypocellular and diffusely fibrotic.
  - Megakaryocytes are large, dysplastic, and abnormally clustered.
- **LAP score:** Raised
- **Philadelphia chromosome:** Negative.
- JAK2 V617F mutation occurs in ~50% patients. CALR mutation is also present.
- **Serum vitamin B_{12}:** Moderately increased.
- **Radiological examination shows** increased bone density of vertebrate and proximal ends of long bones.

Treatment

No specific therapy exists for primary myelofibrosis

- **Treatment of anemia**
  - Correct other causes of anemia like gastrointestinal blood loss and folic acid deficiency (folic acid 5 mg daily)
  - Packed red cell transfusions
  - Neither recombinant erythropoietin nor androgens (such as danazol) is consistently effective in controlling anemia but can be tried in some patients
  - Glucocorticoids (prednisolone) may control constitutional symptoms and autoimmune complications
  - Combination with low-dose thalidomide (50–100 mg/day) with prednisolone can control anemia and splenomegaly in a significant number of patients
- **Treatment of splenomegaly**
  - **Patients with cellular bone marrow and marked leukocytosis**: Busulphan 2 mg daily
  - Indications for splenectomy in selected cases

    - With hypersplenism
    - If splenomegaly impairs alimentation and should be performed before cachexia sets in
  - Splenic irradiation: To reduce splenic size is reserved for patients, who cannot undergo splenectomy. Patients often develop severe cytopenias
  - Hydroxyurea is useful to control splenomegaly, but can produce myelosuppression that may exacerbate underlying anemia.
- **Treatment of extramedullary hematopoiesis:** By low-dose irradiation
- **Curative treatment: Allogeneic bone marrow transplantation** is the only curative treatment. It should be performed in younger patients as most patients in IMF are above 60 years of age
- **Others**
  - Allopurinol can control hyperuricemia
  - Etanercept (TNF-α antagonist) used in patients with severe constitutional features
  - JAK2 inhibitors ruxolitinib is used in clinical practice

Prognosis

Median survival varies from 27 to 135 months and depends on prognostic factors **(Box 9.18)**.

Box 9.18: Shows poor prognostic factors.

- Age >65 years
- Presence of blasts in peripheral blood
- Hemoglobin level <10 g/dL
- Presence of constitutional symptoms
- Total WBC count >25,000/mm^3

(WBC: white blood cell)

Myelophthisis

Q. Write short note on myelophthisis and its causes.

Fibrosis of the bone marrow can occur as a primary hematologic disease is known as primary myelofibrosis (myeloid metaplasia), and as a secondary reactive process, known as myelophthisis (secondary myelofibrosis).

Causes of myelophthisis (other causes of myelofibrosis) are presented in **Box 9.19**. These causes may also produce splenomegaly.

Box 9.19: Causes of secondary myelofibrosis.

Malignant conditions

Hematological

- Leukemia
  - Acute leukemia (lymphoid/myeloid)
  - Chronic myeloid leukemia
  - Hairy cell leukemia
- Multiple myeloma
- Polycythemia vera
- Hodgkin's lymphoma
- Essential thrombocytosis

Nonhematological

- Metastasis to marrow
  - Carcinoma breast, lung or prostate
  - Neuroblastoma

Nonmalignant conditions

- Infections
- Human immunodeficiency virus (HIV) infection
- Tuberculosis
- Exposure to thorium dioxide
- Systemic lupus erythematosus
- Renal osteodystrophy
- Hyperparathyroidism
- Radiation therapy or treatment with radiomimetic drugs
- Gaucher disease

Q. How will you differentiate chronic myeloid leukemia from myelofibrosis?

Differences between chronic myeloid leukemia from myelofibrosis have been shown in **Table 9.41.**

TABLE 9.41: Difference between chronic myeloid leukemia from myelofibrosis.

Features	*Chronic myeloid leukemia*	*Myelofibrosis*
Total leukocyte count	Markedly raised usually more than 20,000/µL	May be raised, but always less than 20,000/µL
Peripheral blood		
Peripheral smear	Shows full range of granulocyte precursors, predominantly mature forms	Shows leukoerythroblastosis with tear drop cells
Nucleated red cells	Few or absent	Numerous
Thrombocytopenia	Occurs late	Common
Marrow fibrosis	Uncommon and minimal	Common and dense
LAP (leukocyte alkaline phosphatase) score	Very low, usually <5	High, usually >100
Philadelphia chromosome	Positive	Negative
Serum vitamin B_{12} levels	Very high	Moderately raised

MYELODYSPLASTIC SYNDROMES

Q. Describe the etiology, classification, clinical features, diagnosis and treatment of myelodysplastic syndrome (MDS).

Definition

Myelodysplastic syndromes (now renamed Myelodysplastic neoplasms in WHO 2022) are a heterogeneous group of acquired clonal stem cell disorders characterized by:

- Progressive cytopenias (low blood cell counts)
- Dysplasia in one or more major cell lines (erythroid, myeloid and megakaryocytic forms)
- Ineffective hematopoiesis
- Increased risk of development of AML
- A subtype of myeloid neoplasms.

Etiology

- In primary MDS the exact cause is not known, however genetic factors may play a role.
- Causes of secondary/t-MDS: Exposure to radiation, benzene, postchemotherapy (particularly alkylating agents and topoisomerase inhibitors), viruses, cigarette smoking, and PNH.
- Median age is 65 years.

WHO (2022) Classification of MDS

The revised WHO (2022) diagnosis and classification of MDS introduce refinements in morphologic interpretation, cytopenias assessment, and genetic information. Cytopenia is necessary for diagnosis of any MDS and in WHO (2008) classifications, MDS nomenclature included references to "cytopenia" or to specific types of cytopenia (e.g., refractory anemia). Present WHO (2022) classification, gemetic characterization is playing a very important role. The new subgrouping is intended to provide a more accurate classification and thus basis for targeted therapies. The distinction between single and multilineage dysplasia is now optional. The subgroup "MDS, unclassifiable" is no longer used in the new WHO classification **(Table 9.42)**.

Clinical Features

- Usually found in patients above 60 years and slightly more common in males.
- Detected incidentally on routine blood examination in about 50% of patients.
- Symptoms are due to cytopenias which may be single-lineage cytopenia, bicytopenia, or pancytopenia. Symptoms include:
  - Weakness (anemia)
  - Infections (leukopenia)
  - Hemorrhage (thrombocytopenia).

TABLE 9.42: WHO (2016) classification, peripheral smear and bone marrow findings of myelodysplastic syndromes.

Disease	*Dysplastic lineages*	*Cytopenias*[1]	*Ring sideroblasts as % of marrow erythroid elements*	*Bone marrow (BM) and peripheral blood (PB) blasts*
➢ MDS with single lineage dysplasia (MDS-SLD)	1	1 or 2	<15%/<5%[2]	BM <5%, PB <1%, no Auer rods
➢ MDS with multilineage dysplasia (MDS-MLD)	2 or 3	1–3	<15%/<5%[2]	BM <5%, PB <1%, no Auer rods
➢ MDS with ring sideroblasts (MDS-RS)				
– MDS-RS with single lineage dysplasia (MDSRS-SLD)	1	1 or 2	≥15%/≥5%[2]	BM <5%, PB <1%, no Auer rods
– MDS-RS with multilineage dysplasia (MDS-RS-MLD)	2 or 3	1–3	≥15%/≥5%[2]	BM <5%, PB <1%, no Auer rods
➢ MDS with isolated del (5q)	1–3	1–2	None or any	BM <5%, PB <1%, no Auer rods
➢ MDS with excess blasts (MDSEB)				
– MDS-EB-1	0–3	1–3	None or any	BM 5–9% or PB 2–4%, no Auer rods
– MDS-EB-2	0–3	1–3	None or any	BM 10–19% or PB 5–19% or Auer rods
➢ MDS, unclassifiable (MDS-U)				
– With 1% blood blasts	1–3	1–3	None or any	BM <5%, PB = 1%[3], no Auer rods
– With single lineage dysplasia and pancytopenia	1	3	None or any	BM <5%, PB <1%, no Auer rods
– Based on defining cytogenetic abnormality	0	1–3	<15%[4]	BM <5%, PB <1%, no Auer rods
➢ Refractory cytopenia of childhood	1–3	1–3	None	BM <5%, PB <2%

[1] Cytopenias defined as hemoglobin <10 g/dL, platelet count <100 × 10^9/L, and absolute neutrophil count <1.8 × 10^9/L; rarely, MDS may present with mild anemia or thrombocytopenia above these levels. PB monocytes must be <1 × 10^9/L.

[2] If *SF3B1* mutation is present.

[3] 1% PB blasts must be recorded on at least two separate occasions.

[4] Cases with ≥15% ring sideroblasts by definition have significant erythroid dysplasia, and are classified as MDS-RS-SL.

- Extramedullary hematopoiesis may cause hepatomegaly and splenomegaly but is uncommon.
- About 10–40% progresses to AML because of which MDS was referred to as preleukemic syndrome.

Diagnosis

- Minimal morphologic criterion for the diagnosis of an MDS: Dysplasia in at least 10% of cells of any one of the myeloid lineages.
- Complete blood count: May give clues to this diagnosis.
- **Peripheral smear:**
    - **RBC:** Mild-to-moderate degree of macrocytic or dimorphic anemia with evidence of dyspoiesis.
    - **WBC** count may be normal or low. Neutropenia with few blasts. Number of blasts determines the type of MDS (**Table 9.42**). The cytoplasm of neutrophils is hypogranular or agranular. The nuclei of neutrophils may show hyposegmentation with only two nuclear lobes (Pseudo–Pelger–Hüet cells), hypersegmentation or ringed neutrophils.
    - **Platelets:** Variable thrombocytopenia, presence of large hypogranular or giant platelets is seen.
    - **NAP score** is moderately or severely decreased.
- **Bone marrow:** The most characteristic features are varying degree of dyspoietic (disordered) differentiation affecting all nonlymphoid lineages (erythroid, granulocytic, monocytic, and megakaryocytic) associated with cytopenias.
- **Cytogenic study of the marrow:** Most important for establishing the diagnosis. Chromosome abnormalities of chromosome 5 or 7 are frequent.

Treatment

- Therapy is supportive:
    - Packed red cell transfusion for anemia
    - Platelet transfusions for bleeding due to thrombocytopenia
    - Antibiotic therapy for infections
    - Iron chelators to reduce iron overload from multiple transfusions
- EPO and G-CSF may be useful in some patients, to ameliorate symptoms
- Others: Use of thalidomide, lenalidomide (a derivative of thalidomide), 5-azacitidine and decitabine. 5-azacytidine and decitabine (hypomethylating agents) may reduce requirements of blood transfusion and to retard the progression of MDS to AML. Lenalidomide is found useful in the 5q-syndrome
- Allogeneic hematopoietic stem cell transplantation: Curative. However, it may be performed in less than 5–10% of patients because MDS is most common during seventh or eighth decade of life

PLASMA CELL NEOPLASMS

Q. Write short essay/note on plasma cell neoplasms/disorders.

Classification of plasma cell proliferative disorders has been shown in **Table 9.43**.

TABLE 9.43: Classification of plasma cell proliferative disorders.

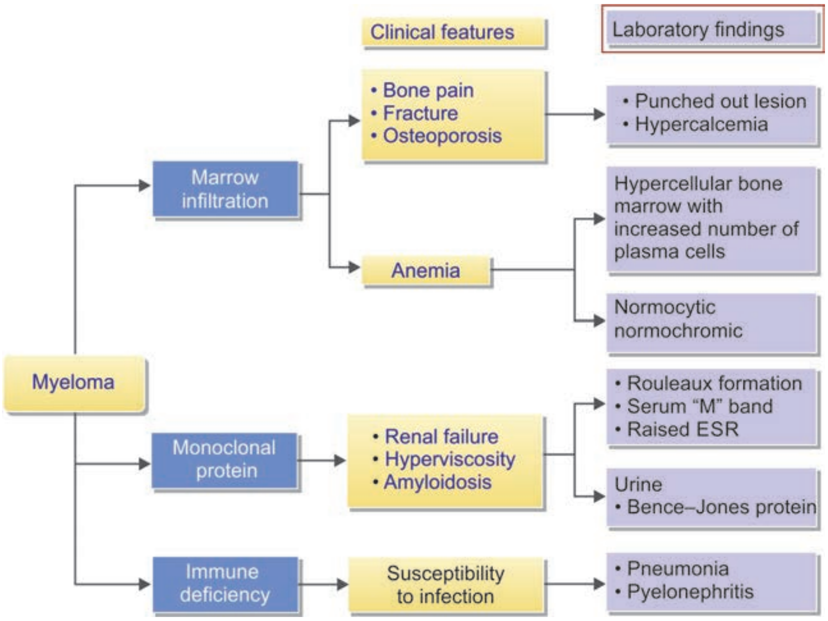
Monoclonal gammopathies of undetermined significance (MGUS) ➢ Benign (IgG, IgA, IgD, IgM, and rarely, free light chains) ➢ Associated neoplasms or other diseases not known to produce monoclonal proteins ➢ Biclonal gammopathies ➢ Idiopathic Bence Jones proteinuria	**Malignant monoclonal gammopathies** ➢ Multiple myeloma (IgG, IgA, IgD, IgE, and free light chains) – Overt multiple myeloma – Smoldering multiple myeloma – Plasma cell leukemia – Nonsecretory myeloma – IgD myeloma – Osteosclerotic myeloma (POEMS syndrome) – Solitary plasmacytoma of bone – Extramedullary plasmacytoma ➢ Waldenström's macroglobulinemia ➢ Other lymphoproliferative diseases
Heavy chain diseases (HCDs) ➢ γ-HCD ➢ α-HCD ➢ μ-HCD	
Cryoglobulinemia	**Primary amyloidosis (AL)**

Multiple Myeloma

Q. Discuss the immunopathology, pathology, clinical features, investigations, diagnosis, and treatment of multiple myeloma.

- Multiple myeloma is a malignant plasma cell neoplasm derived from a single clone plasma cells of the bone marrow and produces multiple, lytic bone lesions.
- Plasma cells are derived from B lymphocytes.
- Normal plasma cells secrete equal quantities of heavy and light chains. But the neoplastic plasma cells frequently synthesize excess of light (L) or heavy (H) chains along with complete Igs. Rarely, only light chains or heavy chains are produced.
- The excess of free light chains are small with low molecular weight and therefore excreted in the urine. They are known as Bence–Jones proteins.
- **Classification of myeloma:** It is based on the type of paraprotein secreted namely: (1) IgG (55%), (2) IgA (25%), (3) IgD

FLOWCHART 9.3: Clinical features and laboratory findings in myeloma.



Clinical features
Laboratory findings
• Bone pain
• Fracture
• Osteoporosis
• Punched out lesion
• Hypercalcemia
Marrow infiltration
Hypercellular bone marrow with increased number of plasma cells
Anemia
Normocytic normochromic
Myeloma
• Rouleaux formation
• Serum "M" band
• Raised ESR
Monoclonal protein
• Renal failure
• Hyperviscosity
• Amyloidosis
Urine
• Bence–Jones protein
Immune deficiency
Susceptibility to infection
• Pneumonia
• Pyelonephritis

(uncommon), (4) IgE (uncommon), and (5) light chain disease (20%). In nonsecretory myeloma, there is no M-protein in the blood or urine but bone marrow shows plasmacytosis.

- The cause of multiple myeloma is unclear. Exposure to radiation, benzene, and other organic solvents, herbicides, and insecticides may play a role. Multiple myeloma has been reported in familial clusters of two or more first-degree relatives and in identical twins.

Clinical Features

- Insidious in onset.
- **Age and gender:** Peak incidence is seen during 6th to 7th decade, and males are more affected than females.
- Symptoms **(Flowchart 9.3 and Table 9.44)**.
    - Some patients may be asymptomatic, and is accidentally detected during the preclinical phase.

Mnemonic to remember common symptoms of multiple myeloma **(Box 9.20)**.

Box 9.20: Mnemonic to remember common symptoms of multiple myeloma.

CRAB: C = Calcium (elevated), **R** = Renal failure, **A** = Anemia, **B** = Bone lesions.

Osteosclerotic Myeloma (POEMS Syndrome)

This syndrome is characterized by polyneuropathy, organomegaly, endocrinopathy, M-protein, and skin changes (POEMS). The major clinical features are a chronic inflammatory-demyelinating polyneuropathy with predominantly motor disability and sclerotic skeletal lesions.

TABLE 9.44: Clinical features in multiple myeloma based on involved organ/system.

Involved organ/system	***Features (Box 9.20)***
Bone	➢ Localized bony swellings over vertebrae, skull, sternum, ribs, and clavicle ➢ Bone pain due to pathological fractures, backache due to involvement of vertebra (60%) ➢ Neurological symptoms of sensory and/or motor loss due to lesion in the vertebra compressing the spinal cord nerve root
Bone marrow	Anemia, leukopenia, and thrombocytopenia
Immune system	Humoral immune deficiency leading to increased susceptibility to infections (recurrent infections), particularly of the respiratory system and urinary tract
Renal damage is multifactorial due to Bence–Jones proteinuria, hypercalcemia, humoral immune deficiency	Nephrocalcinosis, amyloidosis, renal insufficiency (renal failure in 20–30%), infections, or nephrotic syndrome
Bleeding tendency due to thrombocytopenia	Purpura, epistaxis, gastrointestinal bleeding
Cryoglobulinemia and hyperviscosity (uncommon) syndrome	Hyperviscosity may affect the: ➢ CNS (leading to confusion, headache, vertigo, nystagmus, postural hypotension, and dizziness) ➢ Retina (producing blurred vision, retinal venous congestion, papilledema) ➢ Congestive cardiac failure (CVS)
Neurological manifestations	Amyloid peripheral neuropathy, carpal tunnel syndrome, and compressive myelopathy

(CNS: central nervous system)

Diagnosis of Multiple Myeloma

Q. Write short essay/note on diagnosis and management of multiple myeloma.

Requires at least two of the following:

Smoldering (asymptomatic) multiple myeloma

- Smoldering multiple myeloma is defined by the presence of serum M-protein level greater than 3 g/dL and/or 10% or more plasma cells in bone marrow and patients are asymptomatic.
- This entity lies in between multiple myeloma and monoclonal gammopathy of uncertain significance. Patients with smoldering multiple myeloma carry a much higher risk of progression to myeloma or related malignancy compared to monoclonal gammopathy of uncertain significance (MGUS).

- Monoclonal immunoglobulin (M protein) or light chains in the blood (>3 g/dL) and/or urine
- Infiltration of bone marrow with (clonal) plasma cells (≥10%) or plasmacytoma
- Evidence of myeloma-related organ or tissue impairment (≥1)-CRAB
  - Hypercalcemia: Serum (ionized) >5.5 mEg/L
  - Renal insufficiency creatinine clearance <40 mL/min, calcium >2.75 mmol/L, or >0.25 mmol/L than the ULN
  - Anemia (hemoglobin or 2 g/dL below the LLN)
  - Lytic bone lesions and/or osteoporosis
- Other criteria
  - Free light chain ratio between involved to uninvolved light chains >100
  - Presence of >1 bone lesion on magnetic resonance imaging (MRI)
  - Bone marrow plasma cell percentage >60

Investigations in Multiple Myeloma

- **Peripheral blood**
  - Usually shows anemia, leukopenia, thrombocytopenia, and raised erythrocyte sedimentation rate (ESR).
  - Peripheral blood smear: May show **rouleaux formation** due to increased immunoglobulins.
- **Bone marrow examination** is important. Normal bone marrow contains 2–10% plasma cells. In myeloma, the bone marrow is **hypercellular** as a result of increased number of plasma cells and **myeloma cells** (neoplastic plasma cells). Increased number of **myeloma cells, more than 30%** of the cellularity is diagnostic.
- **Urine: Bence–Jones proteins** may be present
- **Serum findings:**
  - **Serum microglobulin:** It is a useful **prognostic marker** and **high values signify poor prognosis.**
  - **Hypercalcemia** is due to extensive osteolytic lesions and osteoporosis and there are also increased levels of serum phosphate.
  - Serum alkaline phosphatase: Usually normal in the absence of complications.
  - Blood urea and serum creatinine raised in 20% of cases and along with electrolytes are used to assess renal function.
  - Serum proteins: Total serum protein level is increased, albumin is decreased and globulins are markedly increased.
  - Serum uric acid: Raised.
  - Serum immunoglobulin estimation reveals a reduction of normal immunoglobulins below normal levels.
- **Electrophoretic studies on serum and urine:** Electrophoretic studies reveal raised levels of immunoglobulins in the blood and/or light chains (Bence–Jones proteins) in the urine. The monoclonal immunoglobulin (M-protein) is identified as abnormal protein "spikes" in serum or urine electrophoresis. The type of immunoglobulin can be determined by immunofixation. The most common M-protein is IgG type, followed by IgA.
- **Radiological examination:**
  - Reveals generalized osteoporosis.
  - Radiographs of flat bones: Such as **skull (Fig. 9.35), vertebral bodies, ribs, and pelvis** show the characteristic **punched-out osteolytic lesions**.
  - Collapse of multiple vertebrate is a common finding.
- MRI and positron emission tomography (PET): May detect bone involvement when skeletal survey is normal.

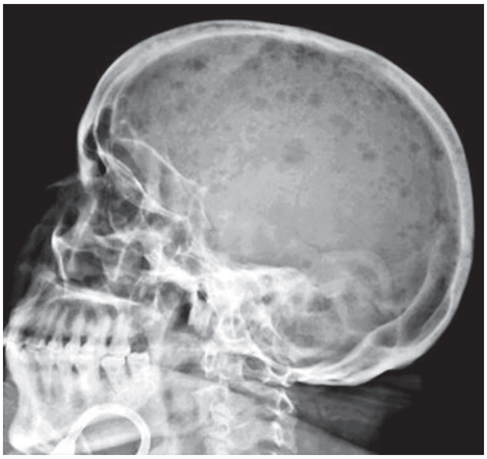


FIG. 9.35: X-ray of skull in myeloma showing punched out lesions.

Staging (Tables 9.45 and 9.46)

Treatment

General measures

- High fluid intake of about 3 L/day to treat renal impairment and hypercalcemia
- Prompt treatment of infections with antibiotics
- Treatment of anemia may require blood transfusion and erythropoietin often helps
- Analgesics to be given for relief of bone pain
- Allopurinol 300 mg daily should be given to reduce/prevent hyperuricemia and urate nephropathy

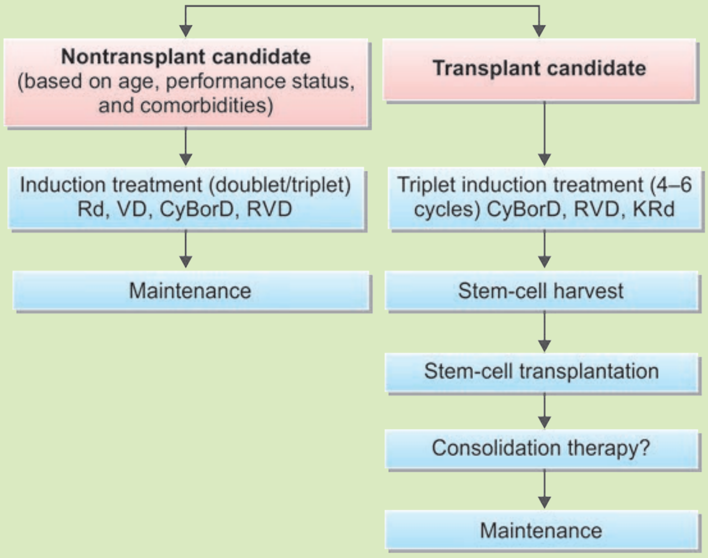
TABLE 9.45: Modified from Durie–Salmon staging.

Stage	*Criteria*
Stage-I	➢ Low M-component: IgG <5 g/dL, IgA <3 g/dL, urine Bence–Jones protein <4 g/24 hours ➢ Normal hemoglobin, serum calcium, Ig levels (non-M protein)
Stage-II	Overall values between stage I and III
Stage-III	One or more of the following: ➢ Hemoglobin <8.5 g/dL, serum calcium >12 mg/dL ➢ High M-component: IgG >7 g/dL, IgA >5 g/dL, urine light chain >12 g/24 hours ➢ Advanced multiple lytic lesions on X-rays
Subclassification based on renal function ➢ Subclass A = Serum creatinine <2 mg/dL ➢ Subclass B = Serum creatinine >2 mg/dL	

TABLE 9.46: International staging system.

Stage	*Characteristic features*	*Median survival*
I	Serum β2-microglobulin <3.5 mg/dL and serum albumin >3.5 g/dL	62 months
II	Serum β2-microglobulin <3.5 mg/dL and serum albumin <3.5 g/dL and or serum β2-microglobulin <3.5–5.5 mg/dL	44 months
III	β2-microglobulin <5.5 mg/dL	29 months

- Hyperviscosity syndrome is managed by plasmapheresis
- Bisphosphonates (e.g., zoledronate, pamidronate, clodronate) which inhibit osteoclast activity. Long-term treatment with this, reduce skeletal events such as pathological fracture, cord compression, and bone pain. An important complication of bisphosphonates is osteonecrosis of jaw
- Orthopedic assistance and physiotherapy can significantly improve the quality of life
- Renal failure: Treated by rehydration and oral prednisolone **(Fig. 9.36)**



Nontransplant candidate (based on age, performance status, and comorbidities)
Transplant candidate
Induction treatment (doublet/triplet) Rd, VD, CyBorD, RVD
Triplet induction treatment (4–6 cycles) CyBorD, RVD, KRd
Maintenance
Stem-cell harvest
Stem-cell transplantation
Consolidation therapy?
Maintenance

FIG. 9.36: Initial approach to treatment of symptomatic multiple myeloma. (CyBorD: Cyclophosphamide, bortezomib, and dexamethasone; KRd: Carfilzomib, lenalidomide, and low-dose dexamethasaone; Rd: Lenalidomide and low-dose dexamethasone; RVD: Lenalidomide, bortezomib, and dexamethasone; VD: Bortezomib and dexamethasone).

Autologous stem cell transplantation

Young patients (<65 years) without renal failure: Standard treatment is first-line high-dose chemotherapy for myeloablation (melphalan 200 mg/m^2 intravenously) to maximum response and then an autologous stem-cell transplantation

Chemotherapy

Regimen used

- Bortezomib, lenalidomide, dexamethasone (VRd)
- Daratumumab, lenalidomide, dexamethasone (DRd)
- Bortezomib, cyclophosphamide, dexamethasone (VCd)
- Bortezomib, thalidomide, dexamethasone (VTd)
- Carfilzomib, lenalidomide, dexamethasone (KRd)

Older patients

- Thalidomide combined with the alkylating agent (melphalan or cyclophosphamide or chlorambucil) and prednisolone. Thalidomide is teratogenic. Recent studies have suggested that combination with thalidomide, results in improved response rates and overall survival, albeit with increased toxicity **(Box 9.21)**
- Bortezomib is a proteasome inhibitor, which is used for upfront and relapsed is combined with doxorubicin and dexamethasone
- Lenalidomide in combination with steroids has been tried

Younger patients (<65 years)

- Bortezomib, cyclophosphamide and dexamethasone. OR Newer drugs include carfilzomib, Ixazomib, pomalidomide, daratumumab, and elotuzumab
- Orally active cyclophosphamide, thalidomide, and dexamethasone-based induction (CTD) followed by a high-dose melphalan autograft

Box 9.21: Median survival.

- Patients with advanced myeloma: 7–8 months
- With good supportive care and chemotherapy: 3–5 years. Asymptomatic stage I patients are generally not given chemotherapy
- Young patients with intensive therapy may live longer

Radiotherapy

- Effective for local problems like severe bone pain, pathological fractures, and tumorous lesions
- As an emergency treatment of spinal cord compression complicating extradural plasmacytomas

Renal Involvement in Multiple Myeloma

Q. Write short note on the cause of renal failure of multiple myeloma.

- Renal involvement is observed in 50% of myeloma patients.
- Renal failure develops in ~25% of patients with multiple myeloma.
- Various factors contributing to renal failure in multiple myeloma are:
  - **Tubular damage** from excretion of light chains (Bence–Jones proteinuria).
  - Hypercalcemia resulting in **nephrocalcinosis** and renal damage.
  - **Amyloid deposition** in the glomeruli (renal amyloidosis).
  - Hyperuricemia producing in **urate nephropathy**.
  - **Recurrent urinary tract infections**.
  - **Infiltration** of the kidney **by myeloma cells**.

Poor Prognostic Factors in Multiple Myeloma

Q. Write short note on the indications of poor prognosis in multiple myeloma.

Poor prognostic factors in multiple myeloma have been shown in **Box 9.22**.

Box 9.22: Poor prognostic factors in multiple myeloma.

- High levels of β2-microglobulin
- High serum calcium >12 g/dL at presentation
- Advanced lytic bone lesions
- Renal failure
- Low serum albumin
- Low hemoglobin (<8.5 g/dL)
- Thrombocytopenia
- Plasma cell leukemia

Radiographic Features in Multiple Myeloma

Q. Write short note on the role of radiographic examination in the diagnosis of multiple myeloma.

Radiographic features in multiple myeloma have been shown in **Table 9.47.**

TABLE 9.47: Radiographic features helpful in the diagnosis of multiple myeloma.

Site of X-ray	*Appearance*
Skull and pelvis	Multiple punched out osteolytic lesions osteoporosis
Chest	Pathological fractures and punched out lesions of ribs, clavicle, and scapulae osteoporosis
Spine	Collapse of multiple vertebrae osteoporosis
Kidney, ureter, and bladder (KUB)	Nephrocalcinosis

Monoclonal Gammopathy of Uncertain Significance

Q. Write short essay/note on monoclonal gammopathy of uncertain significance (MGUS).

Definition: MGUS is defined as presence of serum M-protein concentration lower than 3 g/dL, bone marrow clonal plasma cells <10% plasma cells, and no end organ damage [CRAB (*refer* **Box 9.20**) no hypercalcemia, no renal impairment, no anemia, or no osteolytic lesions] or no evidence of other B-cell neoplasms.

- MGUS is one of the most common plasma cell dyscrasias, occurring in about 3–5% of general population above the age of 50 years.
- **Progression:** MGUS should be considered as preneoplastic condition. It can progress to multiple myeloma, Waldenstrom's macroglobulinemia, primary AL amyloidosis, or a lymphoproliferative disorder at a rate of 1–1.5% per year. Risk of progression to multiple myeloma and related disorders depends upon:
  - Size of M-component (risk of progression with an M-protein value of 1.5 g/dL almost twice that of a patient with an M-protein value of 0.5 g/dL)
  - Type of M-component (IgM and IgA increased risk compared to IgG), and
  - Abnormal free light chain ratio (kappa; lambda ratio-normal being 0.26–1.65).
- Follow-up: Patients should be followed with serum protein electrophoresis at 6 months and, if stable, can be followed every 1–2 years.
- No treatment is indicated.

Differences between multiple myeloma and monoclonal gammopathy of undetermined significance have been shown in **Table 9.48**.

Solitary Plasmacytoma

Q. Write short essay/note on solitary plasmacytoma of bone.

- Solitary plasmacytoma (osseous plasmacytoma) is a solitary tumor occurring in the bone consisting of collection of monoclonal plasma cells.

- Comprises 3–5% of plasma cell neoplasms.
- **Sites:** Common sites are bones with active hematopoiesis and usually occur in the same sites as in multiple myeloma (vertebrae, ribs, skull, pelvis, femur, clavicle, and scapula).
- **Clinical features:** Localized bone pain or pathological fracture. Vertebral lesions may produce neurologic symptoms secondary to spinal cord or root compression.
- **Investigations:**
    - M-protein in serum or urine observed 24–72% of patients by immune fixation
    - MRI is useful to rule out occult systemic disease.
- **Treatment:** Local control is achieved by radiotherapy. Up to two-thirds of patients develop systemic disease.
- **Prognosis:** Median survival is 7–12 years.

TABLE 9.48: Differences between multiple myeloma and monoclonal gammopathy of undetermined significance (MGUS).

Characteristic features	***Multiple myeloma***	***MGUS***
M-protein	Found in serum and/or urine except in patients with nonsecretory	Intact immunoglobulin (e.g., IgG, IgM, IgA)
Bone marrow	Clonal plasma cells 10% or more	➤ Clonal plasma cells <10% ➤ No evidence of other B-cell proliferative disorders
Organ/tissue involvement	At least one of the following: ➤ Serum calcium (ionized) >5.5 mEq/L ➤ Renal insufficiency (creatinine >2 mg/dL) ➤ Anemic (hemoglobin <10 g/dL) ➤ Bone involvement—osteolytic bone lesions and/or osteopenia	No hypercalcemia, renal impairment, anemia or bone involvement

Solitary Extraosseous Plasmacytoma

Q. Write short essay/note on solitary extraosseous plasmacytoma.

- Extraosseous (extramedullary) plasmacytoma are localized plasma cell neoplasms that arise in tissues other than bone.
- Comprises 3–5% of all plasma cell neoplasms.
- **Sites:**
    - Upper respiratory tract (80%): Oropharynx, nasopharynx, sinuses, and larynx.
    - Other sites: GI tract, lymph nodes, bladder, central nervous system (CNS), breast, thyroid, testis, parotid, and skin.
- Only about 20% of patients have M protein (most commonly IgA).
- **Diagnosis:** Requires exclusion of occult systemic disease by extensive radiographic imaging.
- **Treatment:** Eradicated with local radiation therapy.
- **Prognosis:**
    - About 15% of patients subsequently develop multiple myeloma.
    - About 70% of patients remain disease free at 10 years.

Plasma Cell Leukemia

Q. Write short essay/note on plasma cell leukemia.

- Plasma cell leukemia (PCL) is the term used when the peripheral blood has more than 20% plasma cells with an absolute plasma cell count of 2000/μL or greater.
- Classification: Plasma cell leukemia may be classified as:
    - Primary plasma cell leukemia: It develops without any preceding evidence of multiple myeloma. It is diagnosed in the leukemic phase (60%). It develops in younger individuals and presents with hepatosplenomegaly and lymphadenopathy, a higher platelet count, few bone lesions, mild serum M-protein component, and longer survival rate when compared to those with secondary plasma cell leukemia.
    - Secondary: When leukemic transformation develops in a patient with multiple myeloma (40%).
- It is an aggressive disease associated with a high tumor burden and extramedullary dissemination.

Waldenstorm Macroglobulinemia

Q. Write short essay/note on Waldenstrom macroglobulinemia.

- Waldenstrom macroglobulinemia is a syndrome characterized by IgM monoclonal gammopathy sufficient to cause a hyperviscosity of the blood and bone marrow infiltration.
- Most commonly occurs in association with lymphoplasmacytic lymphoma. The tumor cells undergo terminal differentiation to plasma cells and secrete monoclonal IgM.
- It occurs in older adults (median age 60 years).

Clinical Features

May be asymptomatic.

- Usual presenting complaints are nonspecific and include weakness, fatigue, and weight loss. Symptoms develop due to:
  - **Tumor infiltration:** Most patients present with weakness and fatigue due to anemia caused by marrow infiltration. Other features include fever, night sweats, weight loss, lymphadenopathy, hepatomegaly, and splenomegaly.
  - **Monoclonal protein:** About 10% of patients have autoimmune hemolysis caused by cold agglutinins (monoclonal IgM bind to red cells at temperatures of less than 37°C). IgM may be associated with systemic amyloidosis. IgM-secreted by the tumor, because of its large size, at high concentrations increases the viscosity of the blood, giving rise to hyperviscosity syndrome. Features of hyperviscosity syndrome are:
    - Visual impairment associated with venous congestion (e.g., blurring or loss of vision)
    - Neurologic problems (e.g., dizziness, headache, vertigo, nystagmus, hearing loss, ataxia, paresthesias, diplopia)
    - Bleeding
    - Cryoglobulinemia produces symptoms such as Raynaud phenomenon and cold urticaria
  - Tumor cells can infiltrate organs and result in hepatomegaly, splenomegaly, and lymphadenopathy in about 20% patients.

Treatment

- It is a chemotherapy- and immunotherapy-sensitive disease controllable with currently available therapies.
- No specific treatment needed for patients who do not have systemic symptoms.
- Single agent therapy with rituximab alone is used in symptomatic patients with modest hematologic compromise, IgM-related neuropathy, or hemolytic anemia unresponsive to corticosteroids.
- Combination chemotherapy and rituximab (anti-CD20): Patients with severe constitutional symptoms, profound hematologic compromise, bulky disease, or hyperviscosity syndrome should be treated with the dexamethasone, rituximab and cyclophosphamide Or bortezomib, dexamethasone, and rituximab or bendamustine rituximab.
- **Plasmapheresis:** Most of IgM secreted by tumor cells is intravascular. Patient with symptoms due to high IgM levels (such as hyperviscosity and hemolysis) should first undergo plasmapheresis which helps in alleviating these symptoms.

Diagnosis

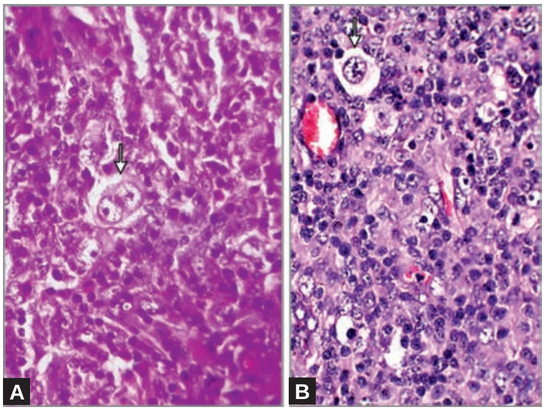
- **Demonstration of monoclonal IgM:** By serum electrophoresis, sample may require warming to 37°C, to avoid interference of cold agglutinins. Immunofixation is required to characterize monoclonal protein.
- **Bone marrow aspirate and biopsy:** It shows more than 10% lymphoplasmacytic cells (CD20$^+$).
- **Prognosis:** Transformation to large-cell lymphoma occurs but is uncommon. Median survival is 4 years.

HODGKIN LYMPHOMA

Q. Discuss the pathological classification, clinical features, clinical staging, investigations, diagnosis, and treatment/management of Hodgkin's lymphoma.

Q. PE29.9 Discuss the etiology, clinical presentation and management of lymphoma in children.

- Hodgkin lymphoma (HL) is a malignant lymphoma characterized by a heterogeneous cellularity comprising of **minority** (1–3%) of specific **neoplastic cells** (Hodgkin cells and Reed–Sternberg cells—**Figs. 9.37A and B)** in a "characteristic background" of reactive non-neoplastic cells (majority) of various types.
- **Cell of origin:** The neoplastic Reed–Sternberg cells are derived from germinal center or immediate post-germinal center B-cells indicating that most HLs are unusual tumors of B-cell origin.
- **Age:** Bimodal age incidence
  - One pack in young adults (15–35 years)
  - Other peak in older adults (45–75 years)
- The neoplastic cells in HL are **Reed–Sternberg cells (Figs. 9.37A and B)** and its variants.
- Immunophenotype:
  - Reed–Sternberg cells in classical forms of HL are CD15$^+$ and CD30$^+$.
  - Reed–Sternberg cells in lymphocyte predominance HL are CD15$^-$ and CD30$^-$.



FIGS. 9.37A AND B: Microscopic appearance of Hodgkin lymphoma showing RS cells and Hodgkin cells within the background of mixed population of reactive cells.

Etiology

- **EBV:** Young adults, who have had previous EBV infection (infectious mononucleosis), have an increased risk of developing HL and the EBV genome is frequently identified in the Reed–Sternberg cells.

- **Genetic factors** may play a role because HLA subtypes, particularly HLA-B18, are higher in patients with HL.
- **Immune status:** HL seems to be more frequent in immunocompromised patients or those with autoimmune diseases, such as rheumatoid arthritis.

Classification of Hodgkin Lymphoma

Rye classification (Table 9.49): According to this HL was divided into four types and the prognosis varies depending upon the histological type. The nodular sclerosing type is the most common.

TABLE 9.49: Rye classification of Hodgkin lymphoma.

Histological type	*Prognosis*
Lymphocyte predominant	Very good
Nodular sclerosing	Good
Mixed cellularity	Fair
Lymphocyte depleted	Poor

WHO classification of Hodgkin lymphoma has been shown in Box 9.23. It is the presently followed classification.

Box 9.23: WHO classification of Hodgkin lymphoma.

- Classical Hodgkin lymphoma (>95%)
- Nodular sclerosis (NS) classic Hodgkin lymphoma
- Mixed cellularity (MC) classic Hodgkin lymphoma (most common type in India)
- Lymphocyte-rich (LR) classic Hodgkin lymphoma
- Lymphocyte depletion (LD) classic Hodgkin lymphoma
- Nodular lymphocyte predominance (LP) Hodgkin's lymphoma (<5%)

Clinical Manifestations

- **Most common presentation:** Painless enlargement of one lymph node group (unifocal origin) usually of cervical lymph node, consistency of lymph nodes is described as "Indian rubber" consistency. Then it spreads in a predictable manner to the adjacent lymph node group (contiguous spread).
- **Other presentation**
  - Localized disease of the mediastinum (often young women), with cough due to mediastinal lymphadenopathy or axillary nodes, and rarely in the abdominal, pelvic or inguinal nodes.
  - Generalized disease: With hepatosplenomegaly and constitutional "B" symptoms is uncommon in the beginning, but may become prominent as the disease advances.
  - Rare sites: It includes Waldeyer's ring, mesenteric, epitrochlear, and popliteal nodes.
  - Involvement of extralymphatic organs: Not common and may occur in the later stages.
- Classical **Pel–Ebstein fever:** It occurs in a cyclical pattern, characterized by several days or weeks of fever alternating with afebrile periods. It is rarely seen.
- Alcohol-induced pain at the site of lymphadenopathy.
- Pruritus is troublesome at times.
- **Nephrotic syndrome:** It may develop due to immune complex deposition in the kidneys. It is associated with depressed cell-mediated immunity and increases the risk of infections like herpes zoster, tuberculosis, and infections with Cryptococci/*Cytomegalovirus* and *Candida* species.
- Symptoms due to compression of various organs by lymph node masses or infiltration of various organs may develop with mediastinal involvement. These include dysphagia, dyspnea, Horner's syndrome, hoarseness of voice, superior vena cava syndrome, and inferior vena cava obstruction.

Clinical staging: It is currently according to the Cotswolds modification of the Ann Arbor classification **(Table 9.50)**.

- Lymphatic structures: It includes lymph nodes, spleen, thymus, Waldeyer's rings, appendix and Peyer's patches; liver, and bone marrow are excluded.
- Each stage is further divided into A or B based on the absence or presence of systemic symptoms (B symptoms), respectively.

Investigations

- **Peripheral blood:** Normocytic normochromic anemia is common and in advance stage, microcytic anemia develops due to defective utilization of iron. Total leukocyte count is usually normal, but sometimes may show neutrophil leukocytosis. Eosinophilia is observed in ~20% of patients and thrombocytosis in some patients. Lymphopenia (indicates lymphocyte depletion) is associated with bad prognosis. In the terminal stages, there may be leukopenia and thrombocytopenia.
- **Serum alkaline phosphatase:** If raised usually indicate bone marrow or liver involvement.
- **ESR:** It may be raised
- **Biopsy:** Fine needle aspiration of involved lymph node may be helpful in the diagnosis.
  - Lymph node biopsy: Surgically or by percutaneous needle biopsy under radiological guidance will establish the diagnosis.
  - Liver biopsy may be useful for diagnosis in patients with hepatomegaly.
- **Staging of HL (Table 9.50):** It is important not only for predicting the prognosis but also for guiding the choice of therapy. This involves careful physical examination and investigations such as: (1) Chest radiographs, (2) liver function tests, (3)

TABLE 9.50: Clinical staging of Hodgkin lymphomas (Cotswold revision of Ann Arbor staging classification).

Stage	*Definition*
I	Involvement of a single lymph node region or lymphoid structure (e.g., spleen, Waldeyer's ring, thymus) or involvement of a single extralymphatic site
II	➢ Involvement of two or more lymph node groups on same side of diaphragm (mediastinum is a single site; hilar nodes, when involved on both sides, constitute stage II disease) ➢ Localized contiguous involvement of only one extranodal organ or site and lymph node region(s) on the same side of the diaphragm (IIE) ➢ Number of anatomic sites should be indicated by suffix (e.g., II_3)
III	Involvement of lymph node regions or structures on both sides of the diaphragm, which may also be accompanied by involvement of the spleen (IIIS) or by localized involvement of only one extranodal organ site (IIIE) or both (IIISE)
III_1	With or without splenic, hilar, celiac, or portal nodes
III_2	With paraaortic, iliac, or mesenteric nodes
IV	Diffuse or disseminated involvement of one or more extranodal organs or tissues, with or without associated lymph node involvement

E: *Involvement of a single extranodal site, or contiguous or proximal to known nodal site of disease*
A: *No "B" symptoms*
B: *Place the patient in the "B" category when at least one of the following is observed:*

- *Unexplained weight loss >10% of bodyweight during 6 months before staging*
- *Recurrent unexplained fever >38° C during the previous month*
- *Recurrent heavy night sweats during the previous month*

Lymphatic structures: *Lymph nodes, spleen, thymus, Waldeyer's rings, appendix and Peyer's patches. Liver and bone marrow are excluded*
Each stage is further divided into A or B based on the absence or presence of systemic symptoms (B symptoms), respectively.

renal function tests, (4) abdominal ultrasound, (5) bone marrow trephine and aspirate (indicated in patients with clinically advanced disease, i.e., stage III, IV, those with "B" symptoms and those who are HIV-positive) and (6) CT scans of neck, chest, abdomen, and pelvis.

- **PET scan:** It is utilized for staging as well management of HL.

Management

Aim of treatment: Curative intent with expectation of success. Patients with localized or good-prognosis disease receive a brief course of chemotherapy followed by radiotherapy to sites of node involvement and cured HD in >90% of cases. Presently, patients with all stages of HL are treated initially with chemotherapy. Patients with more extensive disease or those with B symptoms receive a complete course of chemotherapy.

Chemotherapy: Combination chemotherapy has been shown to be highly effective. Popular chemotherapy regimens **(Table 9.51 and Fig. 9.38)** used is as follows:

TABLE 9.51: Popular chemotherapy regimens used in the treatment of Hodgkin lymphoma.

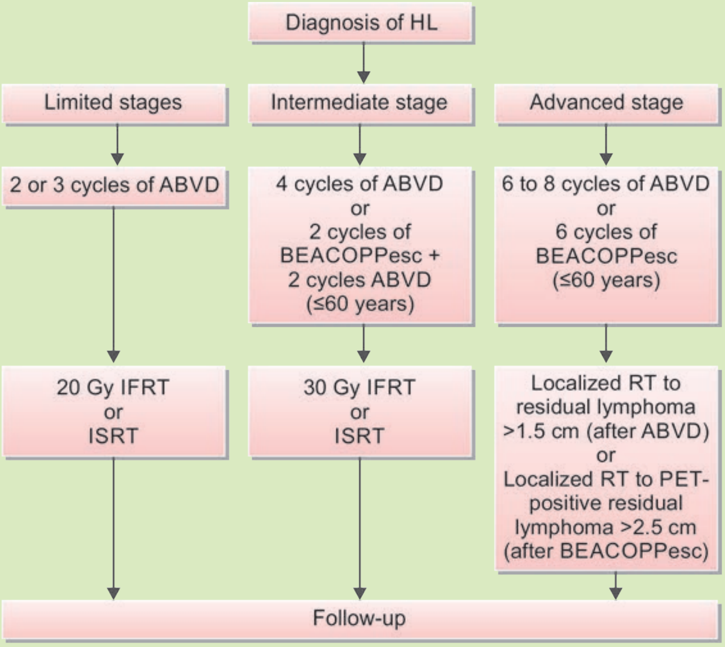
Regimen	*Drugs used*
ABVD	Doxorubicin (adriamycin), biomycin, vinblastine, dacarbazine
MOPP	Mechlorethamine (mustine hydrochloride), vincristine (oncovin), procarbazine, and prednisone
ABVD/MOPP	Alternating cycles of MOPP and ABVD
BEACOPP escalated	Bleomycin, etoposide, adriamycin, cyclophosphamide, vincristine, procarbazine, prednisone in escalated dose

Treatment plan for adults with HL (Table 9.52)

Early stage, "low-risk": Moderate chemotherapy, consisting of 2–4 cycles of ABVD followed by involved field irradiation (20–30 Gy). It has a 90% cure rate.

Advanced disease (including locally advanced unfavorable early stage):

- Cyclical chemotherapy with 6–8 cycles of ABVD with involved field irradiation to sites which were initially bulky



Diagnosis of HL
Limited stages
Intermediate stage
Advanced stage
2 or 3 cycles of ABVD
4 cycles of ABVD or 2 cycles of BEACOPPesc + 2 cycles ABVD (≤60 years)
6 to 8 cycles of ABVD or 6 cycles of BEACOPPesc (≤60 years)
20 Gy IFRT or ISRT
30 Gy IFRT or ISRT
Localized RT to residual lymphoma >1.5 cm (after ABVD) or Localized RT to PET-positive residual lymphoma >2.5 cm (after BEACOPPesc)
Follow-up

FIG. 9.38: Popular chemotherapy regimens used in the treatment of Hodgkin lymphoma (HL).

TABLE 9.52: Treatment plan for adults with Hodgkin lymphoma.

Stage of Hodgkin lymphoma	*Prognostic category*	*Choice of treatment*
IA or IIA, no bulky disease*		ABVD × 4 if complete remission after 2 cycles or ABVD × 2 + involved-region radiation therapy (IRRT)
IB, IIB, or any stage III or IV or bulky disease, any stage	≤3 adverse factors**	ABVD until 2 cycles past complete remission (minimum 6, maximum 8)
	≥4 adverse factors**	BEACOPP escalated

*Bulky = largest diameter of any single mass equal to or greater than 10 cm.
**Adverse factors: Male sex, older than 45 years of age, stage IV, hemoglobin less than 10.5 g/dL, WBC count greater than 15,000/mL, lymphocyte count less than 600/mL or less than 8% of the white cell count, or serum albumin less than 4 g/dL.

- ***Stanford V* for ABVD:** Consists of weekly chemotherapy regimen of doxorubicin, vinblastine, mechlorethamine, etoposide, vincristine, bleomycin, and prednisone) administered for 12 weeks and includes radiation therapy
- Escalated BEACOPP (bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, prednisone, and procarbazine)

Autologous bone marrow transplantation is successful in about 40% cases even after the failure of chemotherapy.

Radiation therapy (Fig. 9.39)

- **Extended-field radiation (EFRT):** Radiation field includes not only the clinically involved nodes, but also the adjacent, clinically uninvolved sites (e.g., mantle field or inverted-Y field).
- **Involved-field radiation (IFRT):** Radiation field is limited to the clinically involved regions (e.g., mediastinal plus low bilateral supraclavicular field which covers the entire mediastinum)
- **Involved-site radiation (ISRT):** Radiation field includes only pre- and postchemotherapy tumor volumes plus a margin of healthy tissue to accommodate uncertainties in determining the prechemotherapy tumor volume
- **Involved-node radiation (INRT):** Radiation field includes pre- and postchemotherapy nodal volumes plus a very limited margin of healthy tissue (0.5–1 cm)

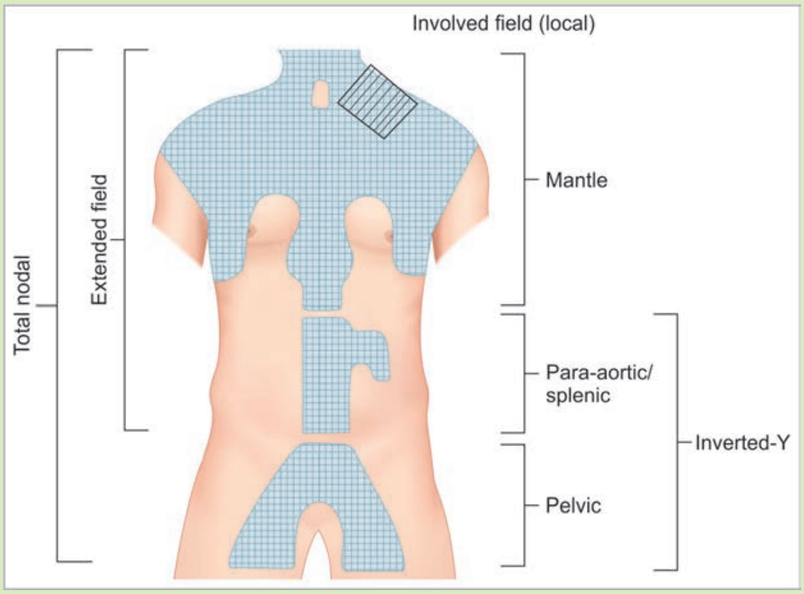


FIG. 9.39: Radiation therapy.

Late complications: Develop due to high cure rates achieved with modern treatment.

- Development of second malignancies: Such as acute leukemia and solid organ cancers. Acute leukemia usually develops within 10 years of use of alkylating agents in combination with radiotherapy. The risk is higher with MOPP as compared to ABVD. Solid organ cancers usually develop after 10 years of radiotherapy.
- Cardiac failure and accelerated coronary artery disease: Following radiotherapy pulmonary fibrosis and hypothyroidism.

NON-HODGKIN LYMPHOMA

Q. Discuss the pathological classification, clinical staging, clinical features, investigations, and management of non-Hodgkin lymphoma (NHL).

- Lymphomas represent solid tumors of the immune system.
- Lymphomas can be divided into two major categories: (1) NHL and (2) HL.
- About 80% of NHL are of B-cell origin and 20% of T-cell origin.

Etiology

Various factors associated with the development of NHL have been shown in **Table 9.53**.

Pathology and Classification

Grading of NHL (Box 9.24)

- Size of the lymphoid cells is a guide to prognosis. NHL with small lymphoid cells (mature lymphocytes) is associated with low-grade and those with large lymphoid cells (immature lymphoid cells) are found in high-grade disease.

TABLE 9.53: Various factors associated with the development of non-Hodgkin lymphoma.

Genetic factors/inherited immune disorders	***Acquired immune disorders***
➢ Wiskott–Aldrich syndrome ➢ Ataxia–telangiectasia	➢ Solid organ transplantation ➢ Acquired immunodeficiency syndrome (AIDS) ➢ Rheumatoid arthritis, systemic lupus erythematosis (SLE) ➢ Sjögren's syndrome ➢ Hashimoto thyroiditis
Infectious agents	***Occupational and environmental exposure***
➢ **Human T-lymphotropic virus type 1** with adult T-cell leukemia/ lymphoma ➢ **Human herpesvirus 8** (Kaposi's sarcoma) associated with primary effusion lymphoma ➢ **Hepatitis C virus:** Lymphoplasmacytic lymphoma and splenic marginal zone lymphoma ➢ ***Helicobacter pylori*:** Associated with gastric lymphoma of extranodal marginal zone/ mucosa ➢ **Epstein–Barr virus:** Associated with Burkitt lymphoma and HL, mucosa-associated lymphoid tissue (MALT)	➢ Ionizing radiation ➢ Herbicides ➢ Organic solvents ➢ Hair dyes ➢ Ultraviolet light ➢ High-fat diets and nitrates in drinking water ➢ Heavy smoking associated with follicular lymphoma

- Follicular lymphomas are low grade and have good prognosis, and most diffuse lymphomas are high grade and have poor prognosis.

Box 9.24: Grading of non-Hodgkin lymphoma (NHL).

Indolent or low grade
- Small lymphocytic
- Follicular, predominantly small cleaved cells
- Follicular, mixed, small cleaved and large cleaved cells

Highly aggressive/high grade
- Large cell, immunoblastic (B or T cell type)
- Lymphoblastic
- Small noncleaved cell (Burkitt's and non-Burkitt's)

Aggressive/intermediate grade
- Follicular, predominantly large cell, cleaved and/or noncleaved
- Diffuse, small cleaved cell
- Diffuse, large cell, cleaved or noncleaved

WHO classification of lymphoid neoplasm (Table 9.54)

It requires immunophenotyping, cytogenetics, fluorescent in situ hybridization (FISH), and antigen receptor gene rearrangement studies.

TABLE 9.54: WHO classification of the lymphoid neoplasms (2016).

Precursor B-cell neoplasms (immature B cells)	**Precursor T-cell neoplasms** (immature T cells)
Precursor-B lymphoblastic leukemia/lymphoma	Precursor-T lymphoblastic leukemia/ lymphoma
Peripheral B-cell neoplasms (mature B cells)	**Peripheral T-cell and NK-cell neoplasms** (mature T cells and natural killer cells)
Chronic lymphocytic leukemia	T-cell prolymphocytic leukemia
B-cell prolymphocytic leukemia	Large granular lymphocytic leukemia
Lymphoplasmacytic lymphoma	Mycosis fungoides/Sezary syndrome
Mantle cell lymphoma	Peripheral T-cell lymphoma, unspecified
Follicular lymphoma	Anaplastic large cell lymphoma
Marginal zone lymphoma	Angioimmunoblastic T-cell lymphoma
Hairy cell leukemia	Adult T-cell leukemia/lymphoma
Plasmacytoma/plasma cell myeloma	Extra nodal NK/T-cell lymphoma
Diffuse large B-cell lymphoma	
Burkitt lymphoma	

Clinical Features

- **Age:** NHL can occur at any age, but the peak incidence is around 60 years.
- **Most common presentation:**
  - Painless firm, lymph node enlargement or symptoms due to lymph node mass.
  - Extranodal involvement is more common in T-cell lymphoma and involves the bone marrow, gut, thyroid, lung, skin, testis, brain and more rarely, bone.
  - Bone marrow involvement is more common in low-grade (50–60%) than high-grade (10%) NHL and can produce cytopenia.
  - Primary extranodal lymphomas present with soft tissue masses and symptoms relevant to the site. Waldeyer's ring and epitrochlear lymph nodes are frequently involved.
  - Pressure effects: Due to NHL includes gut obstruction, ascites, superior vena cava obstruction, and spinal cord compression.
  - Involvement of liver and spleen results in hepatosplenomegaly.
  - Patients with lymphoblastic lymphoma often present with an anterior mediastinal mass.
  - Burkitt lymphoma typically disseminates to the bone marrow and meninges and involves extranodal sites.
- It may be associated with "B" or systemic symptoms. These include weight loss, sweats, fever, and itching.
- Immunologic abnormalities: For example, autoimmune hemolytic anemia and immune thrombocytopenia.
- Paraneoplastic neurologic complications of NHL include demyelinating polyneuropathy, Guillain–Barré syndrome, autonomic dysfunction and peripheral neuropathy. Paraneoplastic syndromes associated with NHL can affect the skin

(e.g., pemphigus), kidney (e.g., glomerulonephritis), and miscellaneous organ systems (e.g., vasculitis, dermatomyositis, and cholestatic jaundice).

Clinical Staging (Ann Arbor Classification)

- Same staging system **(Table 9.50)** is used for both HL and NHL.
- Ann Arbor classification is also used for the clinical staging of NHL but is more useful in HL. However, 'B' symptoms are not included as they are not useful in predicting prognosis.

Investigations

Investigations required for staging the disease are the same as that for HL. Laparotomy is rarely required, only when retroperitoneal nodes are involved.

- **Peripheral blood:** Moderate degrees of anemia may be observed when there is significant bone marrow involvement.
  - Blood counts: Usually normal, but few patients may show lymphocytosis.
  - Splenomegaly with hypersplenism or autoimmune hemolytic anemia may lead to reduced hemoglobin level, reticulocytosis, and positive Coombs test.
- **Bone marrow aspiration and trephine biopsy:** It should be performed early, since marrow involvement is common with NHL.
- **Others investigations:**
  - **Immunophenotyping** of surface antigens to distinguish T- and B-cell tumors. This may be done on blood, marrow or lymph node material. It can be performed by flow cytometry and/or immunohistochemistry utilizing a minimal antibody panel (CD45, CD20, and CD3) to identify B, T or NK subtypes.
  - **Immunoglobulin determination:** Some lymphomas are associated with IgG or IgM paraproteins.
  - **Measurement of uric acid levels:** Few very aggressive high-grade NHLs are associated with very high uric acid levels that can precipitate renal failure when treatment is started.
- Human immunodeficiency virus (HIV) testing.
- Serum levels of LDH, β2-macroglobulin, and serum protein electrophoresis are often needed.
- **Diagnostic spinal tap:** Required when a first prophylactic instillation of cytarabine and or methotrexate is indicated in high-risk patients, especially with involvement of CNS, orbit, bone marrow, testis, spine or base of the skull. It is also indicated in HIV-associated lymphoma and highly aggressive lymphoma.

Management (Box 9.25)

Low-grade NHL:	**High-grade NHL:**
Radiotherapy	
Localized stage I disease	➢ In few stages I patients without bulky disease ➢ Residual localized bulk disease after chemotherapy ➢ Spinal cord and other compression syndromes
Chemotherapy	
➢ Oral therapy—chlorambucil (not curative) ➢ Intensive IV chemotherapy in younger patients—better quality of life without any survival benefit	>90% of patients—IV combination chemotherapy—CHOP regimen (cyclophosphamide, doxorubicin, vincristine and prednisolone)
Humanized monoclonal antibody therapy	
➢ Rituximab, ^{131}I-Tositumomab, ^{90}Y-Ibritumomab ➢ Anti-CD20 antibody rituximab(R) alone or with chemotherapy i.e., R-CVP-recommended as first-line therapy	➢ Combination with CHOP chemotherapy, rituximab(R) improves overall survival ➢ R-CHOP: First-line therapy for those with stage II or greater diffuse large-cell lymphoma
Autologous bone marrow transplantation	
	In relapsed chemosensitive disease

Diffuse Large B-cell Lymphoma (DLBCL)

- Most common lymphoma in the adult population and constitutes about 30–50% of all NHL.
- Present with painless lymphadenopathy at one or several sites. Intra-abdominal disease presents with bowel symptoms due to compression or infiltration of the GIT.

Treatment

Refer treatment of high-grade NHL mentioned earlier.

Q. How do you differentiate Hodgkin's lymphoma from non-Hodgkin's lymphoma?

Differences between HL and NHL have been shown in **Table 9.55**.

Box 9.25: Regimen for non-Hodgkin's lymphoma.

Regimen		
CHOP-R	***CVP-R***	***FCR***
➢ Cyclophosphamide ➢ Doxorubicin ➢ Vincristine ➢ Prednisone ➢ Fixed dose rituximab	➢ Cyclophosphamide ➢ Vincristine ➢ Prednisone ➢ Fixed dose rituximab	➢ Fludarabine ➢ Cyclophosphamide ➢ Rituximab

TABLE 9.55: Differences between Hodgkin and non-Hodgkin lymphoma.

Characteristics	***Hodgkin lymphoma***	***Non-Hodgkin lymphoma***
Age	Bimodal peak incidence, 15–35 years and 45–70 years	Peak incidence around 60 years
"B" symptoms	More common	Less common
Alcohol-induced discomfort in lymph nodal region	Common	Not observed
Disease at the time of diagnosis	Usually well localized	Usually widespread
Site of involvement	Unifocal origin and arises in a single node or chain of nodes (cervical, mediastinal, para-aortic)	Mostly involves multiple peripheral nodes (multicentric origin)
Pattern of spread	Orderly spread by contiguity in a predictable fashion	Noncontiguous spread in an unpredictable fashion
Epitrochlear node	Rarely involved	Commonly involved
Mediastinal involvement	Common	Uncommon
Mesenteric nodes and Waldeyer's ring	Rarely involved	Commonly involved
Bone marrow involvement	Late	Early
Extranodal involvement	Uncommon	Common
Characteristic of neoplastic cells	Neoplastic cells—Hodgkin or Reed-Sternberg cells form minor tumor cell mass (1–5%)	Neoplastic cells form the major tumor cell mass
Number of neoplastic cells	Few neoplastic cells (RS cells)	Majority of the cells are neoplastic

Burkitt Lymphoma

Q. Write short note on Burkitt lymphoma/leukemia.

- Burkitt lymphoma is a highly aggressive, often extranodal B-cell lymphoma.
- Most common childhood malignancy worldwide and majority in children, but can occur in all ages.
- Male: female ratio is 3:1.
- Often presents with extranodal involvement or as leukemia.
- Burkitt lymphoma (about 80% of cases) is associated with a specific chromosomal translocation involving *myc* oncogene from chromosome 8 to the immunoglobulin (Ig) heavy chain region on chromosome 14.[t(8;14)].
- Categories of Burkitt lymphoma are explained in **Box 9.26**.

Box 9.26: Three categories of Burkitt lymphoma.

- Endemic (African)
- Sporadic (nonendemic) Burkitt lymphoma
- Immunodeficiency-associated (HIV) lymphomas

Clinical Features

- **Endemic form:** Occurs in Africa. Affects children and adolescents. Associated with Epstein–Barr virus infection and corresponds to the distribution of malaria. Involves extranodal sites, particularly the jaw, gastrointestinal tract and gonads. Commonly presenting as a rapidly growing jaw tumor in a young child (4–7 years). Involvement of mandible and maxillary bone leads to deformity, loosening of teeth, and extrusion of the eye with loss of vision.
- **Sporadic from:** It presents as an abdominal mass.
- **Immunodeficiency-associated** (HIV) form: It usually occurs with CD4 counts above 200/mm^3. It again presents with abdominal involvement.
- **Abdominal involvement:** It presents as mass due to bilateral involvement of kidneys adrenals, ovaries, bowel, and lymph nodes.
- **Other sites of involvement:** CNS (common in adults), long bones, salivary glands, thyroid, testes, heart, breast, and bone marrow.

Investigations

- **Histological examination:** Involved tissues show diffuse monotonous infiltrate of medium-sized (intermediate-sized) lymphoid cells, numerous mitoses, and plenty of tumor cells undergoing apoptosis. The nuclear remnants of these apoptotic cells are phagocytosed by benign macrophages creating a characteristic **"starry sky" pattern** (resembling stars in the sky) **(Fig. 9.40)**.
- **Chromosome analysis:** The most common form of translocation results in the movement of the *MYC*-containing segment of chromosome 8 to chromosome 14q32, placing it close to the *IGH* gene. The genetic notation for the translocation is t(8:14) (q24; q32). As a result of translocation, MYC protein is overexpressed and results in cell proliferation and stimulates apoptosis.
- **Antibodies to EB viral capsid antigen:** It may be detected (in endemic type, and in many with sporadic and HIV-associated tumors).

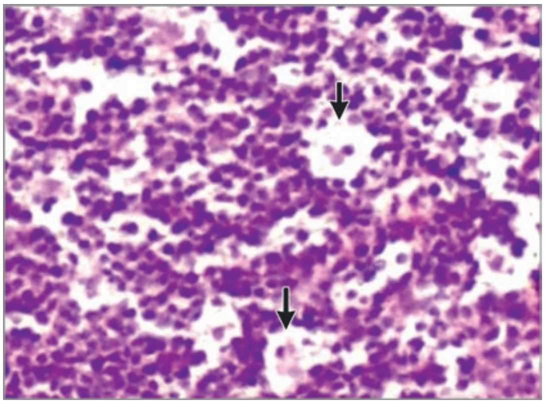

FIG. 9.40: Burkitt lymphoma composed of medium-sized lymphoid cells admixed with benign macrophages (arrows) giving a "starry sky" appearance.

Management

- Treatment must be initiated urgently with curative intent whenever feasible.
- Adequate hydration prior to the initiation of specific therapy to prevent the risk of tumor lysis syndrome.
- Standard treatment comprises of high-intensity, brief-duration cyclical combination chemotherapy. Regimens include:
  - CHOP (cyclophosphamide, hydroxydoxorubicon or doxorubicin, oncovin (vincristine), prednisolone) regimen **OR**
  - Rituximab plus EPOCH (etoposide, prednisolone, oncovin (vincristine), cyclophosphamide and doxorubicin) **OR**
  - CODOX-M/IVAC regimen (cyclophosphamide, vincristine, doxorubicin, methotrexate/ifosfamide, etoposide, or VP-16, cytarabine)
- Prophylactic CNS therapy is essential, intrathecal methotrexate or cytosine arabinoside is given in addition to high-dose systemic administration.
- Cure rates: High as 70–80%.

Adult T-cell Lymphoma/Leukemia

Q. Write short note/essay on adult T-cell lymphoma/leukemia.

- Adult T-cell leukemia/lymphoma is a neoplasm of CD4+ T-cells and develops in adults infected by *human T-cell leukemia virus type 1 (HTLV-1)*.
- Mode of infection of HTLV-1: Transplacental transmission, blood transfusion, or sexual contact.
- Latency period between infection and development of lymphoma is long (10–30 years).
- Four major presentations:
  1. Acute aggressive form: It is characterized by peripheral blood lymphocytosis, lymphadenopathy, hepatosplenomegaly, skin infiltration, hypercalcemia, lytic bone lesions, and raised LDH levels in blood. Opportunistic infections are common. Peripheral smear usually reveals characteristic, neoplastic cells with multilobulated nuclei, and petal-like nuclear lobules connected by thin chromatin strands, known as "cloverleaf" or "flower" cells are found in the involved tissues and peripheral blood. Bone marrow involvement is usually not prominent.
  2. Lymphomatous form: Constitute ~20% of cases and is associated with generalized lymphadenopathy without leukemia.
  3. Chronic form: Constitute ~15% of cases and may have a low level absolute lymphocytosis in the peripheral blood associated with an exfoliative skin rash.
  4. Smoldering form: Constitute ~5% of cases and have a normal peripheral blood lymphocyte count and a small number of circulating tumor cells and skin rashes.

Prognosis: Most cases progress rapidly and are fatal.

Treatment

- Combination chemotherapy prolongs life but does not produce remissions.
- Combination antiretroviral drugs (zidovudine + interferon-α) may be helpful in some patients.

Mucosa-associated Lymphoid Tissue Lymphoma

Q. Write short note/essay on mucosa-associated lymphoid tissue lymphoma or primary gastric lymphoma.

- It is a small-cell NHL of B-cells that is extranodal in origin.
- **Sites:** MALT lymphoma is often localized to the organ from which it arises in ~40% cases and to the organ and surrounding lymph nodes in ~30% cases. Bone marrow involvement is uncommon and occurs in ~15% cases.

  - Gastric type of MALT lymphoma is associated with *H. pylori* infection. Salivary gland MALT is associated with Sjogren's syndrome.
  - Other sites: It may occur in the stomach, orbit, intestine, lung, skin, soft tissue, bladder, kidney, salivary gland, and CNS.
- Age: Mainly in elderly patients with median age of 60 years.
- Gastric type of MALT lymphoma
  - It may present as a mass or produce local symptoms such as upper abdominal discomfort and dyspepsia.
  - Endoscopy: Often mimic benign conditions like chronic gastritis or a peptic ulcer. Multiple biopsies are required for establishing diagnosis.
  - Endoscopic ultrasound (EUS) useful for staging of gastric MALT lymphoma.
  - Low-grade gastric MALT lymphoma can achieve remission in 80% of cases with eradication of the infection.
- Prognosis: Good in most cases with 5-year survival of 75%.

Treatment
- Localized MALT lymphomas can be treated with surgery or local radiotherapy.
  - Anti *H. pylori* therapy in gastric MALToma.
- Extensive disease is treated with single chemotherapy agents like chlorambucil, cyclophosphamide, fludarabine, or cladribine. Combination regimens that include rituximab are also highly effective.

Mycosis Fungoides

Q. Write a short note on mycosis fungoides.

- Mycosis fungoides is a rare type of cutaneous T-cell NHL composed of small to medium-sized lymphoid cells with irregular nuclear outlines.
- Insidious in onset and are derived from $CD4^+$ T cells of skin-associated lymphoid tissue.
- Age: They usually present between 55 and 60 years.
- The tumor cells show epidermotropism (predilection for the epidermis) and dermis.
- Clinical features: There are three stages:
  1. *Patch stage* (inflammatory *premycotic phase)*, characterized by erythematous macules usually occurring on areas not exposed to sunlight.
  2. *Plaque stage*, with elevated scaly plaques which may be pink or red/brown and are often intensely pruritic.
  3. *Tumor stage*, with dome-shaped firm tumors which may ulcerate.
- **Sézary syndrome:** Patients with mycosis fungoides may develop generalized erythroderma and malignant T-cells with serpentine nuclei are found in the peripheral blood and this condition is known as *Sézary's syndrome.*
- **Immunophenotype:** Tumor cells express pan-T-cell markers CD3, CD5 and CD2.
- **Prognosis:** These are indolent tumors with a median survival rate of 8–9 years.

Several rare lymphoproliferative disorders other than lymphoma have distinctive clinical courses.

Treatment
- Localized early-stage mycosis fungoides: Can be cured with radiotherapy, often total-skin electron beam irradiation.
- More advanced stage: Palliative treatment such as topical glucocorticoids, topical nitrogen mustard, phototherapy, psoralen with ultraviolet A (PUVA), and systemic cytotoxic therapy.

HEMATOPOIETIC STEM CELL TRANSPLANTATION

Q. Write short essay/note on hematopoietic stem cells (HSC).

Q. Write a short note on peripheral blood stem cell transplantation.

Q. Write short essay/note on bone marrow transplantation and its indications.

- **Bone marrow transplantation** was the original term used to describe the collection and transplantation of hematopoietic stem cells.
- **Hematopoietic stem cell transplantation** is a preferred term, because the peripheral blood and umbilical cord blood are also used as sources of stem cells.
- **Definition:** Hematopoietic stem cell transplantation is defined as the process of collecting and infusing hematopoietic stem cells obtained from bone marrow (bone marrow transplantation) or peripheral blood (peripheral blood stem cell transplantation).
- **Purpose of HSC transplantation:** To repopulate or replace totally or partly recipient's hematopoietic system. HSC are self-renewing cells which can repopulate all the cell lineages in the blood.
- Major sources of hematopoietic stem cells:
  - Bone marrow: Obtained directly from bone marrow by multiple aspirations from the pelvic bones.
  - Peripheral blood (peripheral blood stem cells).
  - Umbilical cord blood.

Indications for Hematopoietic Stem Cell Transplantation

Q. Write short essay/note on indications for bone marrow/stem cell transplantation.

Indications for hematopoietic stem cell transplantation have been shown in **Box 9.27**.

Box 9.27: Indication for hematopoietic stem cell transplantation.

Red blood cell disorders
- Severe aplastic anemia
- Thalassemia major
- Fanconi anemia
- Sickle cell disease
- Pure red cell aplasia

WBC disorders
- Leukemia
  - Acute lymphoblastic leukemia—relapse after initial chemotherapy induced remission
  - Chronic myeloid leukemia, acute myeloid leukemia
- Myelodysplastic syndromes, myelofibrosis
- Lymphomas: HL, NHL
- Multiple myeloma

Solid tumors, e.g., germ cell tumors, neuroblastoma

Immunological disorders
- Severe autoimmune disorders: Scleroderma, lupus erythematosus
- Immune deficiency syndromes

Categories/Types of Hematopoietic Cell Transplantation

- **Autologous ("from self"):** Stem cells obtained from the recipient (same person). The patient's own HSCs are removed and stored in the vapor phase of liquid nitrogen until required. The source of stem cells may be bone marrow or from the blood. It does not require immunosuppression. However, there is no graft-versus-tumor effect and therefore, there is increased risk of disease relapse or progression compared to allogenic HSC transplantation.
- **Allogeneic ("from different genes"):** HSCs are obtained from a donor-either related (usually an HLA-identical sibling) or from a closely HLA-matched volunteer unrelated donor (VUD).
- **Syngeneic ("from same genes"):** HSCs are obtained from an identical twin.

Main factor for a successful allogenic transplantation is finding of an HLA-matched donor, because it reduces the risk of graft rejection and graft-versus-host disease (GVHD).

Peripheral Blood Stem Cell Transplantation

Definition

It is defined as transplantation of stem cells derived from the peripheral blood of a donor to a recipient (allogenic) or from the patient's own blood (autologous).

Steps

- Hematopoietic stem cells are present in the peripheral blood but in very low concentration (<0.1% of all nucleated cells). To increase their numbers, hematopoietic growth factor (G-CSF or GM-CSF) is administered to the donor (for allogenic stem cell transplant) or to the patient during recovery from intensive chemotherapy (for autologous transplant).
- Stem cells are collected from the blood by apheresis and are infused in the recipient.
- Stem cells engraft in the recipient and is characterized by the recovery of neutrophil count to >500 mm^3 for 3 consecutive days.
- Hematopoietic recovery is more rapid in peripheral hematopoietic stem cell transplantation when compared to bone marrow hematopoietic stem cell transplant.

Umbilical cord blood: It is a good source of HSC with no risk to either infant or mother. Possible contamination of cord blood with CMV and Epstein-Barr virus is also low due to poor transmission from placenta. However, the major disadvantage is that the number of HSCs that can be collected from cord blood is small and an adult might require multiple cord blood donors.

Origin and source of hematopoietic stem cells used for transplantation are presented in **Box 9.28**. Comparison among bone marrow, peripheral blood and cord blood stem cells are presented in **Table 9.56**.

Box 9.28: Origin and source of hematopoietic stem cells used for transplantation.

- ***Origin of hematopoietic stem cells***
  - Autologous
  - Syngeneic
  - Allogeneic
  - Genotypically HLA-identical siblings
  - Phenotypically HLA-identical or HLA-mismatched family members
  - Unrelated volunteer donors
- ***Source of hematopoietic stem cells***
  - Bone marrow
  - Peripheral blood
  - Combination of blood and marrow
  - Umbilical cord blood

Conditioning Regimens

- Necessary before HSC transplantation.
- Types: **Myeloablative or nonmyeloablative** (or reduced intensity).
  - **Myeloablative regimens:** Eliminates malignant cells in the marrow so that transfused HSC can populate the bone marrow and develop.

  - **Nonmyeloablative regimens:** To induce immunosuppression in recipient so that engraftment of donor cells can take place. It is less toxic.
- Complications of conditioning regimens:
  - Usually develop within 30 days and includes infections, nausea, vomiting, alopecia, mucositis and interstitial pneumonia.
  - Veno-occlusive disease of liver characterized by jaundice, ascites, and tender hepatomegaly.
  - Late complications: Infertility, ovarian failure, and secondary malignancies (AML and solid organ malignancies).

TABLE 9.56: Comparison among bone marrow, peripheral blood and cord blood stem cells.

Characteristic	*Bone marrow*	*Peripheral blood*	*Cord blood*
Stem cell content	Adequate	Good	Low
Risk of tumor cell contamination	High	Not applicable	Not applicable
HLA matching	Close matching	Close matching	Less restrictive
Engraftment	Medium	Fastest	Slowest
Risk of acute graft-versus-host disease (GVHD)	High	High	Lowest
Risk of chronic GVHD	Medium	Highest	Lowest

Autologous Stem Cell Transplant

Marrow or peripheral stem cells are obtained from the patient before the high-dose therapy, frozen (cryopreserved) and then reinfused after the high-dose therapy to reconstitute marrow function.

Different steps of autologous stem cell transplantation (Fig. 9.41)

- **Harvesting:** During harvesting, bone marrow and/or peripheral HSCs (identified as CD34+ by immunophenotyping) are collected.
- **Processing of HSCs:** The collected bone marrow or peripheral blood stem cells are suspended in dimethyl sulfoxide (prevents ice crystallization in the cells) and frozen in liquid nitrogen. The HSCs can survive in frozen state for at least 5 years.
- **Conditioning:** Before the autologous transplant, the patient is given a high-dose chemotherapy and/or radiation therapy, sometimes total body irradiation (TBI). This procedure is called conditioning, the purpose of which is to eradicate the recipient's hematopoietic and immune system and also malignant tumor cells if any. Conditioning also makes physical space available for HSCs to engraft. In contrast to allogeneic transplantation, autologous transplantation does not require immunosuppression to prevent GVHD.

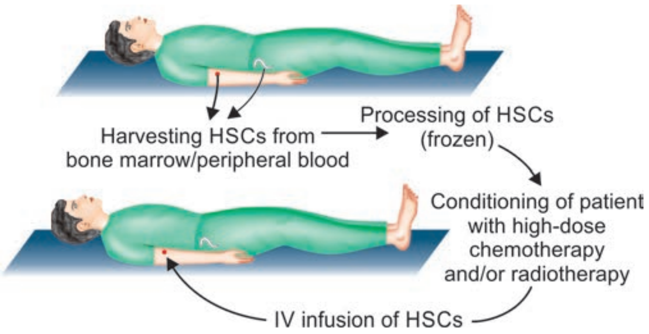

FIG. 9.41: Autologous stem cell transplantation.
(HSCs: Hematopoietic stem cells)

- **Stem cell transplant:** The collected frozen bone marrow or peripheral HSCs are thawed and infused intravenously like a blood transfusion. These stem cells home from the peripheral circulation to the conditioned empty marrow space. Because of conditioning the patient is pancytopenic and requires critical care. The high-dose chemotherapy also causes breakdown of the normal mucosal barriers in the mouth and gut resulting in increased susceptibility to infections and painful ulcerations.
- **Post-transplant engraftment:** During which the hematopoietic cells produce all the three formed elements of the blood.

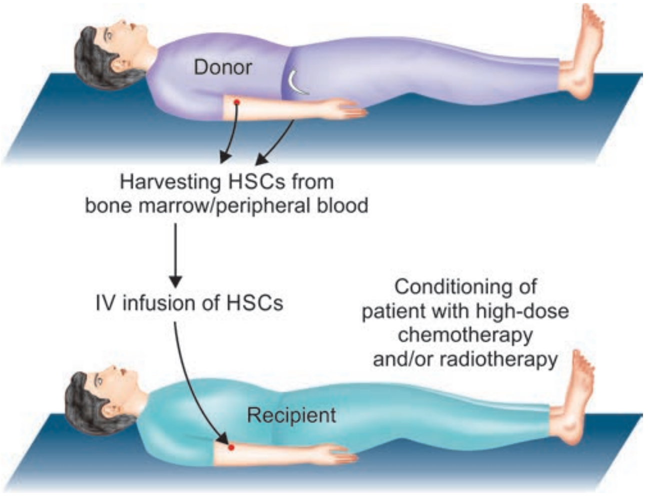

FIG. 9.42: Allogeneic stem cell transplantation.
(HSCs: Hematopoietic stem cells)

Allogenic Bone Marrow Transplantation

The HSCs are obtained from an HLA-matched or HLA-mismatched family member (usually a sibling) or an unrelated donor.

Different steps of allogenic stem cell transplantation (Fig. 9.42)

- **Harvesting:** During harvesting, collected bone marrow and/or peripheral HSCs are mixed with mature WBCs, important being lymphocytes. Mature T lymphocytes are the principal effectors of cell-mediated immunity and both therapeutic benefit and toxicities of allogeneic HSC transplant are due to immunologic reactions between donor T-cells and recipient cells.

- **Conditioning:** This step is similar to autologous HSC transplant. Immunosuppression is to allow engraftment of the transplanted HSCs. The patient's endogenous lymphocytes must be suppressed by immunosuppression so as to prevent GVHD.
- **Stem cell transplant:** The harvested HSCs are infused into the vein just like a blood transfusion. The stem cells travel and reside in the marrow and produce erythrocytes, granulocytes and platelets. This usually takes 3–4 weeks. Patient requires utmost care during this period similar to autologous transplant.
- **Engraftment:** Donor T lymphocytes help donor HSCs engraft. These T lymphocytes are mostly CD8+ and they destroy any remaining host immune cells which may reject the donor HSCs. Depletion of donor T lymphocytes before allogeneic HSC transplant significantly increases the risk of graft failure. But the greatest disadvantage due to the donor T lymphocytes is development of GVHD.

Complications of Hematopoietic Stem Cell Transplantation (Table 9.57)

Autologous HSC transplants have fewer immunologic complications but have higher rates of relapse of the disease after transplant. Allogeneic HSC transplants have lower rates of relapse but have more immunologic complications, including GVHD, which can be fatal.

TABLE 9.57: Complications of hematopoietic cell transplantation.

Vascular access complications	***Hepatic complications***
Graft failure	Sinusoidal obstructive syndrome
Blood group incompatibilities and hemolytic complications	Hepatitis: Infectious versus noninfectious
Acute graft-versus-host disease (GVHD)	**Cardiac toxicity:** Structural (e.g., valvular abnormalities or coronary artery disease) or functional (e.g., cardiomyopathies)
Chronic GVHD	**Lung injury**
Infectious complications	Interstitial pneumonitis: Infectious versus noninfectious
Bacterial infections	Diffuse alveolar hemorrhage
Fungal infections	Engraftment syndrome
Cytomegalovirus infection	Bronchiolitis obliterans
Herpes simplex virus infections	**Kidney and bladder complications:** Hemorrhagic cystitis, nephrotoxicity
Varicella-zoster virus infections	**Endocrine complications**
Epstein–Barr virus infections	**Drug-drug interactions, gonadal dysfunction, thyroid dysfunction**
Adenovirus, respiratory viruses, HHV-6, -7, -8, and other viruses	Growth and development: Growth retardation
Gastrointestinal complications	**Late onset nonmalignant complications**
Mucosal ulceration/bleeding	Osteoporosis/osteopenia, avascular necrosis, dental problems, cataracts, chronic fatigue, psychosocial effects, and rehabilitation
Nutritional support	**Secondary malignancies:** Lymphoma, solid tumors of the tongue, salivary glands, brain, thyroid, bone, malignant melanoma, squamous cell carcinoma, and basal cell carcinoma
	Neurologic complications

- **Infections:** Patients are susceptible to a variety of infections (bacterial, viral, and fungal) due to lack of granulocytes, as well as lack of a functioning immune system. Infections may occur during three different phases after HSC transplantation.
  1. **First phase:** Infections develop due to neutropenia and damage to gastrointestinal mucosal barrier induced by conditioning agents used during transplantation. Source of infection is from oral, skin and gastrointestinal flora.
  2. **Second phase:** It develops during GVHD where T-cell function gets impaired. Patients may develop opportunistic viral and fungal infections.
  3. **Third phase:** It occurs due to chronic GVHD where both B-cell and T-cell functions are impaired. Patients may develop bacterial as well as opportunistic viral and fungal infections.
- **Organ toxicity:** The other complications include damage to GI tract, liver, and lungs.
- **Interstitial pneumonitis:** This is seen in 30–40% of patients and may be fatal in some. Toxicity of radiation and chemotherapy, GVHD and viral, and pneumocystis infections are responsible.
- **Veno-occlusive disease:** VOD results from injury to hepatocytes and endothelium in zone 3 of the liver acinus and obstruction of hepatic sinusoids and venules. The clinical manifestations include jaundice, ascites, and painful hepatomegaly. Tissue plasminogen activator has been used to treat VOD successfully. Severe VOD is often fatal.
- **Graft-versus-host disease:** GVHD is the major complication that follows allogeneic HSC transplant. This is caused by cytotoxic activity of infused donor T lymphocytes reacting against the recipient's tissues/organs (which are considered as foreign to donor T cells).
  - Forms: GVHD can occur in two forms
    1. Acute GVHD: If GVHD occurs before 100 days, it is termed as acute GVHD. It often affects three primary target organs simultaneously, namely skin, gastrointestinal (GI) tract and liver. It causes exfoliative dermatitis, diarrhea, hepatitis and

Three conditions are necessary for the development of GVHD:
1. An immunocompetent graft (i.e., one containing T-cells)
2. HLA mismatch (minor or major) between donor and recipient
3. An immunosuppressed recipient who cannot mount an immune response to the graft.

cholestasis. It develops due to production of cytokines by Th1 cells. HLA mismatch is one of the important risk factor for its development. Treatment includes methotrexate, cyclosporine, antithymocyte globulin, corticosteroids and monoclonal antibodies against T-cells.

2. Chronic GVHD: Occurs after day 100 following transplantation and can affect the skin, GI tract, liver, eyes, lungs, and joints. GVHD is difficult to treat and in severe cases it is usually fatal. It develops due to cytokine production by Th2 cells. Treatment includes cyclosporine and corticosteroids.

DRUGS USED IN HEMATOLOGICAL DISEASES

Antiplatelet Drugs (Table 9.58)

Q. Write a short essay/note on antiplatelet drugs.

Cyclooxygenase Inhibitors

- **Aspirin** is a cheap, effective and most widely used antiplatelet agent.
- **Mechanism of action:** Aspirin inhibits platelet enzyme cyclooxygenase (COX-1 and COX-2) and prevents the synthesis of thromboxane A_2. This results in impairment of platelet secretion and aggregation.
- **Duration of action:** Effects of aspirin on platelet function develop within an hour and lasts for the whole life span of platelets (~7 days).
- **Indications:** Arthritis, secondary prevention of cardiovascular events (acute coronary syndromes, stable angina) in patients with coronary artery, cerebrovascular (transient ischemic attack), or peripheral vascular disease (intermittent claudication).
- **Dose:** Usual dose is 75–325 mg once daily.
- **Side effects:** Dyspepsia to erosive gastritis or peptic ulcers with bleeding and perforation.

TABLE 9.58: Antiplatelet agents by mechanism of action and clinical use.

Cyclooxygenase inhibitors	
Aspirin	Coronary and cerebrovascular disease
Agents that increase cAMP	
Dipyridamole	Coronary, cerebrovascular, peripheral arterial disease
Pentoxifylline	Peripheral arterial disease
Cilostazol	Peripheral arterial disease
ADP receptor blockers	
Ticlopidine	Cerebrovascular disease
Clopidogrel	Coronary, cerebrovascular disease, PCI
Prasugrel	Coronary, cerebrovascular disease, PCI
ADP mimetic	
Cangrelor	Coronary, cerebrovascular disease
Glycoprotein IIb/IIIa inhibitors	
Abciximab	ACS
Eptifibatide	ACS
Tirofiban	ACS

(ADP: Adenosine diphosphate; ACS: Acute coronary syndrome; cAMP: Cyclic adenosine monophosphate; PCI: Percutaneous coronary intervention)

Adenosine Diphosphate (ADP) Receptor Antagonists on Platelets (Thienopyridines)

- Thienopyridines are drugs that selectively inhibit ADP-induced platelet aggregation by irreversibly blocking P2Y12.
- Thienopyridines include **ticlopidine, clopidogrel, and prasugrel**.
- Indications: Reduces the risk of cardiovascular death, MI, and stroke in patients with atherosclerotic disease.
- **Dose:**
  - Ticlopidine: 250 mg twice daily
  - Clopidogrel: 75 mg once daily. Loading dose of 300 mg of clopidogrel is given when rapid ADP receptor blockade is needed such as patients undergoing coronary stenting.
  - Prasugrel: A loading dose of 60 mg, prasugrel produces much more rapid, potent, and consistent inhibition of platelet function than clopidogrel loading dose. It is followed by a maintenance dose of 10 mg once daily.
- **Side effects:**
  - Ticlopidine: Gastrointestinal and hematologic (neutropenia, thrombocytopenia, and thrombotic thrombocytopenic purpura). These side effects usually occur within the first few months of starting treatment.
  - Clopidogrel and prasugrel: Gastrointestinal and hematologic side effects are rare.

Adenosine Reuptake Inhibitors

- **Dipyridamole** is a relatively weak antiplatelet agent.
- Mechanism of action:
  - Inhibits phosphodiesterase and blocks the breakdown of cyclic AMP.
- **Dose:** 25–75 mg three to four times a day. Dipyridamole is more commonly used along with aspirin.
- **Indications:** Coronary artery disease, ischemic stroke or transient ischemic attack. Rarely used at present because of dose inconvenience and side effects.

- Side effects:
  - Due to the vasodilatory **effect**, it can lower the blood pressure and must be used with caution in patients with coronary artery disease.
  - Others: Gastrointestinal complaints, headache, dizziness and hypotension.

Glycoprotein IIb/IIIa Receptor Antagonists (Inhibitors)

- It includes three agents: **Abciximab, eptifibatide, and tirofiban**.
- **Uses:** Parenteral GPIIb/IIIa receptor antagonists are used in acute coronary syndromes, unstable angina and non-ST-elevatin MI percutaneous coronary interventions.
- **Side effects:** Bleeding tendencies and thrombocytopenia. Eptifibatide may produce hypotension.

TABLE 9.59: Classification of anticoagulants.

Parenteral (rapidly acting)	*Oral (slow acting)*
➢ Heparin (unfractionated and low-molecular weight heparins) ➢ Hirudins ➢ Heparinoids ➢ Indirect factor Xa inhibitors (fondaparinux and idraparinux)	➢ Coumarin derivatives: Warfarin sodium, dicoumarol. These are most commonly used. Bishydroxycoumarin dicoumoral, acenocoumarol (nicoumalone), ethylbiscoumacetate ➢ Indandione derivatives: Phenindione, diphenindione (not used clinically) ➢ Direct thrombin inhibitors: Ximelagatran

Anticoagulants

Q. Classify anticoagulants. Write a short essay/note on the commonly used anticoagulants.

Q. Write short note on:

- Indication for anticoagulants.
- Contraindication for anticoagulants.

Classification of Anticoagulants

Classification of anticoagulants has been shown in **Table 9.59**.

Indications for Anticoagulant Therapy

Q. Write a short note on indications for long-term anticoagulation.

Indications for anticoagulant therapy have been shown in **Table 9.60**.

Contraindications for anticoagulation therapy are listed in **Box 9.29**.

TABLE 9.60: Indications for anticoagulant therapy.

Purpose	*Clinical situations*
Urgent and for long-term anticoagulation: It is initiated with heparin and taken over by oral anticoagulants	Thrombosis and thromboembolism: ➢ Atrial fibrillation and cardiac disorders with thromboembolism ➢ Deep venous thrombosis ➢ Stroke in evolution and resistant transient ischemic attacks ➢ Pulmonary thromboembolism Others: ➢ Unstable angina and non-ST-elevation myocardial infarction ➢ Prosthetic valves ➢ Peripheral vascular disease
Anticoagulants for brief periods: Heparin alone is used	Cardiac bypass surgery: ➢ Hemodialysis ➢ Disseminated intravascular coagulation (DIC)

Box 9.29: Contraindications for anticoagulant therapy.

- Bleeding disorders, heparin induced thrombocytopenia
- Severe hypertension, threatened abortion, hemorrhoids, peptic ulcers
- Subacute bacterial endocarditis, tuberculosis
- Ocular and neurosurgery, lumbar puncture
- Chronic alcoholics, cirrhosis, renal failure

Heparin

Unfractionated heparin

Q. Write a short note on (unfractionated) heparin.

Mechanism of action: Heparin acts as anticoagulant by activating antithrombin (previously known as antithrombin III) thereby potentiating its action. The activated antithrombin inhibits clotting enzymes, particularly thrombin and factor Xa.

- **Mode of administration:** Heparin is given parenterally. It is usually administered SC or by continuous IV infusion.
- **Dose:** Initial loading dose of 5,000–10,000 units intravenously, followed by maintenance by any one of the following:
  - Continuous intravenous.
  - Intermittent intravenous/subcutaneous.
- **Methods of anticoagulation:**
  - Total anticoagulation: Continuous intravenous maintenance using an infusion pump at a rate of 1,000 units/hour.
  - Low-dose heparinization (e.g., prophylaxis of DVT): 5,000 units 12 hourly or 8 hourly subcutaneously.
  - For prophylaxis: Fixed doses of 5,000 units SC two or three times daily.
- **Duration of therapy:** Variable, but usually ranges from 7 to 10 days.
- **Monitoring:** Heparin therapy is monitored using activated partial thromboplastin time (aPTT), which is maintained at 1.5 to 2 times the control value.
- **Antidote of heparin:** Protamine sulfate

- **Complications of heparin therapy:** Includes bleeding, heparin-induced thrombocytopenia (HIT), osteoporosis, and osteomalacia (in long-standing therapy). HIT is of two types:

Heparin-induced thrombocytopenia

- **HIT type I:** Benign form develops immediately and often resolves after heparin is discontinued and is probably due to direct platelet-aggregation induced by heparin.
- **HIT type II:** The heparin binds to platelet factor 4 (PF4) released from platelets and forms a complex (heparin/PF4 complex) in the circulation. The antibodies formed against these complexes activate platelets, promoting thrombosis even in the presence of marked thrombocytopenia. It develops 5–10 days after starting heparin therapy. Can occur with all types of heparin.

Treatment of HIT Type II

- Immediately stops all heparin administration.
- Start nonheparin anticoagulants, e.g., lepirudin—a recombinant hirudin, argatroban, danaparoid, fondaparinux and bivalirudin.
- Do not administer warfarin as it can produce gangrene of the limb or necrosis of skin. Vitamin K is administered if HIT is diagnosed after warfarin has already been started.
- Do not administer platelet transfusion even though there is severe thrombocytopenia.

Low-molecular weight heparins (LMWH)

- LMWH are biologically active forms of conventional heparin. The molecular weight ranges from 3,000 to 8,000 Daltons.
- **Mode of action:** They act as anticoagulant primarily by inhibiting activated factor X (Xa) rather than activated factor II (IIa).
- **Advantages:**
    - Can be administered subcutaneously once or twice/day.
    - Pharmacokinetics is predictable and aPTT monitoring is not needed.
    - Less immunogenic and less likely to produce thrombocytopenia.
    - Many patients with DVT (deep vein thrombosis) can be treated on an outpatient basis.
- **Disadvantage:** Higher cost.
- **Commonly available LMWH:** Enoxaparin, dalteparin and tinzaparin.

Warfarin

Q. Write a short essay/note on oral anticoagulants.

- Water-soluble vitamin K antagonist.
- **Mode of action:** Vitamin K is necessary for the synthesis of coagulation factors such as prothrombin (factor II) and factors VII, IX and X and also protein C and protein S. Warfarin type anticoagulants prevents the conversion of vitamin K to its active hydroquinone form and interferes with the synthesis of the above vitamin K-dependent coagulation factors.
- **Monitoring:** Warfarin therapy is monitored using the **PT**.
- **Dose:**
    - Starting dose: Warfarin is started at a dose of 5 mg oral on the first day. Subsequent daily doses are adjusted according to PT (INR) which is maintained at 1.5–3 times the control value.
    - Maintenance dose: Varies from 2.5 to 7.5 mg/day.
- **Duration of therapy:** Variable and may range from 3 months to lifelong.
- **Side effects:** These include bleeding and rarely skin necrosis.
- **Antidotes of warfarin:** Injections of vitamin K_1, 5 mg intravenously or fresh frozen plasma or prothrombin complex concentrate.
- **Contraindications:**
    - Severe uncontrolled hypertension
    - Severe renal or liver failure
    - Pre-existing hemostatic disorders
    - Pregnancy: It crosses the placenta and can cause fetal abnormalities. Therefore, it should not be used during pregnancy.

Reversing warfarin therapy (Table 9.61)

Direct thrombin inhibitors

- **Parenteral: Hirudin**
    - Source: Derived from a medicinal leech.
    - Recombinant form of hirudin, e.g., lepirudin, bivalirudin, and desirudin.

TABLE 9.61: Reversing warfarin therapy.

Indication	*Action*
INR <6	➢ Lower the dose, consider withholding one or more doses ➢ Recheck in 3–7 days
INR 6–10	➢ Lower the dose and withhold 1–3 doses ➢ Consider administering vitamin K, 1–2 mg orally ➢ Recheck INR in 24–48 hours
INR >10	➢ Withhold doses until INR in desired range and cause of elevation ascertained ➢ Give vitamin K, 2–4 mg orally ➢ Recheck INR in 24 hours
Serious bleeding and major overdose	Consider fresh-frozen plasma or prothrombin complex concentrate and give 5–10 mg vitamin K intravenously

  - Mode of action: Acts directly on thrombin.
  - Monitoring: By measuring aPTT.

Clinical indications and use of direct thrombin inhibitors is presented in **Table 9.62**.

Oral

Q. Discuss novel oral anticoagulants (NOACs).

- **Dabigatran** being used for prophylaxis after hip and knee replacement. The major side effect of dabigatran is hemorrhage.
- ***Idarucizumab:*** *Humanized monoclonal antibody fragment (Fab) indicated in patients treated with dabigatran when reversal of the anticoagulant effects is needed for emergency surgery or urgent procedures, or in the event of life-threatening or uncontrolled bleeding.*
- **Rivaroxaban** and **apixaban** are orally administered drug, factor Xa inhibitor available orally administered direct factor Xa inhibitor that produces its anticoagulant effect through reversible binding with the factor Xa molecule. Rivaroxaban can inhibit both free and thrombus associated factor Xa **(Table 9.63)**.

TABLE 9.62: Clinical indications and use of direct thrombin inhibitors.

Agent	*Clinical indication*	*aPTT*
Lepirudin	HIT	ACT
Bivalirudin	Angioplasty, PCI with HIT	aPTT
Argatroban	HIT HIT with PCI	ACT (activated) clotting time

Indirect factor Xa inhibitors

- These include fondaparinux and idraparinux.
- Mode of action: Increases the rate of inactivation of factor Xa by antithrombin, thereby blocking production of thrombin.
- Use: HIT-type II.

TABLE 9.63: Potential advantages and disadvantages of NOACs.

Potential advantages	*Potential disadvantages*
➢ Lower rates of intracranial bleed and hemorrhagic strokes than warfarin ➢ No need for routine laboratory monitoring ➢ Fewer drug or food interactions than warfarin	➢ Higher drug cost; may require prior insurance approval ➢ Lack of availability of a reversal agent ➢ Increased risk of gastrointestinal bleeding ➢ Higher rebound rate of VTE events in patients with poor adherence ➢ No clear efficacy data in certain patient populations (e.g., patients with malignancy)

Fibrinolytic or Thrombolytic Agents

Q. Write a short essay/note on fibrinolytic agents.

Q. Write a short essay/note on thrombolytics.

- Goal of therapy: To produce rapid dissolution of thrombus and restore the blood flow.
- Most fibrinolytic or thrombolytic agents are recombinant forms having plasminogen activator activity.
- Mechanism of action: They convert the proenzyme, plasminogen to active enzyme plasmin. Plasmin then degrades the fibrin of thrombi and produces soluble fibrin degradation products.
- Currently approved fibrinolytic agents are:
  - Streptokinase (STK):
    - Source: It is obtained from β-hemolytic streptococci. It is not an enzyme and does not directly convert plasminogen to plasmin. Instead it forms a complex with plasminogen, it converts other/additional molecules

of plasminogen into plasmin. Since it is obtained from bacteria, it can produce allergic reactions in about 5% of patients.
    - Uses: In acute ST-elevation myocardial infarction and pulmonary embolism.
  - Urokinase (UK): It is used in patients who received STK in the past 6 months and require a thrombolytic agent for MI or pulmonary embolism. It does not produce an allergic reaction.
  - Acylated plasminogen streptokinase activator complex (APSAC) (anistreplase).
  - Recombinant tissue-type plasminogen activator (rtPA): Also known as alteplase or activase is useful in acute thrombotic strokes (within 3 hours of onset) besides acute MI and pulmonary embolism.
  - Prourokinase (pro-UK) like rtPA.
  - Others: Tenecteplase, desmoteplase and reteplase.
- Indications for use of fibrinolytic agents are listed in **Box 9.30**.

Box 9.30: Indication for use of fibrinolytic or thrombolytic agents.

- Acute myocardial infarction
- Massive pulmonary embolism with hypotension
- Acute ischemic stroke (thrombotic or embolic)
- Acute peripheral artery occlusion

Erythropoietin

Q. Write a short essay/note on erythropoietin (EPO), recombinant human erythropoietin (rHuEPO) and darbepoetin alfa.

Q. List the ectopic sources of erythropoietin.

- **Site of production:** This hormone is predominantly produced by the juxtatubular interstitial cells of the renal cortex and to a lesser extent in the liver.
- **Stimulus:**
  - **Hypoxia** is the most potent stimulus for EPO production. In the presence of tissue (renal) hypoxia, kidneys respond by increased production of EPO.
  - **Anemia:** Erythropoietin levels are inversely related to hemoglobin concentrations in the blood. Anemia is another important stimulant.
- **Mode of action:**
  - EPO stimulates erythropoiesis by acting on the marrow erythroid progenitors to enhance their survival, proliferation and differentiation.
  - EPO may also protect neuronal cells from noxious stimuli.

  Ectopic sources of EPO are presented in **Table 9.64**.

TABLE 9.64: Ectopic sources of EPO.

Polycystic kidneys	Cerebellar hemangioblastoma	Uterine leiomyoma
Renal cell carcinoma	Hepatocellular carcinoma	Pheochromocytoma

Recombinant Human Erythropoietin (rHuEPO)

- It has the same biological effects of endogenous erythropoietin and is available as erythropoietin-α and erythropoietin-β.
- **Indications:** In the treatment of:
  - Anemia associated with chronic renal failure.
  - Anemia of chronic inflammation.
  - Anemia (hemoglobin <10 g/dL) in cancer patients given chemotherapy.
  - Zidovudine-induced anemia in HIV patients.
  - Anemic patients undergoing nonvascular surgery to reduce the need for allogeneic blood transfusions.
- **Side effects:** Hypertension, bleeding, headache, arthralgia, nausea, edema, diarrhea, increased risk of thrombosis, pure red cell aplasia, and progression of cancers.

Darbepoetin Alfa

- Produced by recombinant DNA technology in Chinese hamster ovary cells.
- Half-life about 3 times rHuEPO and hence needs to be given less frequently.
- Side-effects similar to rHuEPO.
- Not approved for the treatment of zidovudine-induced anemia and for blood loss during perioperative period.

Hemopoietic Growth Factors

Q. Write a short note on hematopoietic growth factors.

Erythropoietin

Refer above discussion.

Granulocyte Colony Stimulating Factor

- **Indications:**
  - **Primary prophylaxis**
    - To reduce chances of febrile neutropenia following chemotherapy: When the risk of febrile neutropenia is high (>20%) as determined by age, disease characteristics, and myelotoxicity of drugs used.
    - Accelerate hematopoietic recovery after chemotherapy and autologous hematopoietic cell transplantation.
  - **Secondary prophylaxis:** In patients with solid tumors with a previous history of the febrile neutropenia who require high-dose chemotherapy and any dose reduction may compromise treatment outcome.
  - **Patients with neutropenia and fever:** It may be administered to those patients with high risk of infection-related complications, prolonged (>10 days), and severe neutropenia (<100/μL), hypotension, multiorgan dysfunction, or invasive fungal infections. It is not recommended in afebrile patients with neutropenia.
  - **Mobilizing stem cells from bone marrow:** For stem cell transplantation. Both G-CSF and GM-CSF have been used.
- **Disadvantage:** Patients undergoing chemotherapy for breast carcinoma, if treated with G-CSF may develop acute myeloid leukemia or myelodysplastic syndrome. However, the benefit outweighs the possible risks.
- **Dosage:** 15 mg/kg daily by subcutaneous injection. Its pegylated form has a longer duration of action and requires to be given once a day.
- **Adverse effects:** Fever, bone, and joint pains.

Granulocyte-Macrophage Colony-stimulating Factor (GM-CSF)

- **Action:** Increase in neutrophil, eosinophil, macrophage, and sometimes lymphocyte counts.
- **Dosage:** Daily subcutaneous injection of 250 $\mu g/m^2$.
- Both G-CSF and GM-CSF have similar efficacy and indications (refer G-CSF above).

Thrombopoietin

- **Site of production:** Liver and kidney and marrow stromal cells.
- **Action:**
  - Stimulates the survival, proliferation, and differentiation of megakaryocytes and their precursors.
  - Primes mature platelets to aggregate in response to subthreshold levels of thrombin, collagen and ADP.
  - In cancer patients receiving chemotherapy, it has been shown to reduce the duration of post chemotherapy thrombocytopenia.
  - Thrombopoietin is undergoing clinical trials in patients with immune thrombocytopenic purpura.
- **Disadvantage:** Most patients produce antibodies against TPO and therefore, it is not recommended in treatment of any condition.

Treatment: Shows a dramatic response to parenteral vitamin K therapy. Vitamin K may not be effective in the presence of liver cell disease.
Dose: Daily 10 mg of injections of vitamin K.

Vitamin K

Q. PE12.14 Describe the causes, clinical features, diagnosis management and prevention of deficiency of vitamin K.

- Vitamin K is a fat-soluble vitamin and requires bile for its absorption.
- Vitamin K is required by the liver for the production of factors II, VII, IX and X, protein C, and protein S.

Causes of Vitamin K Deficiency

- **Inadequate stores:** As in hemorrhagic disease of the newborn (vitamin K levels are low and are due to lack of gut bacteria and low concentrations of the vitamin in breast milk) and severe malnutrition (especially when combined with antibiotic treatment).
- **Defective absorption:** Diseases that interfere with fat absorption, e.g., obstructive jaundice owing to the lack of intraluminal bile salts, pancreatic disease or small bowel disease.
- **Oral anticoagulant drugs** which are vitamin K antagonists (warfarin therapy).

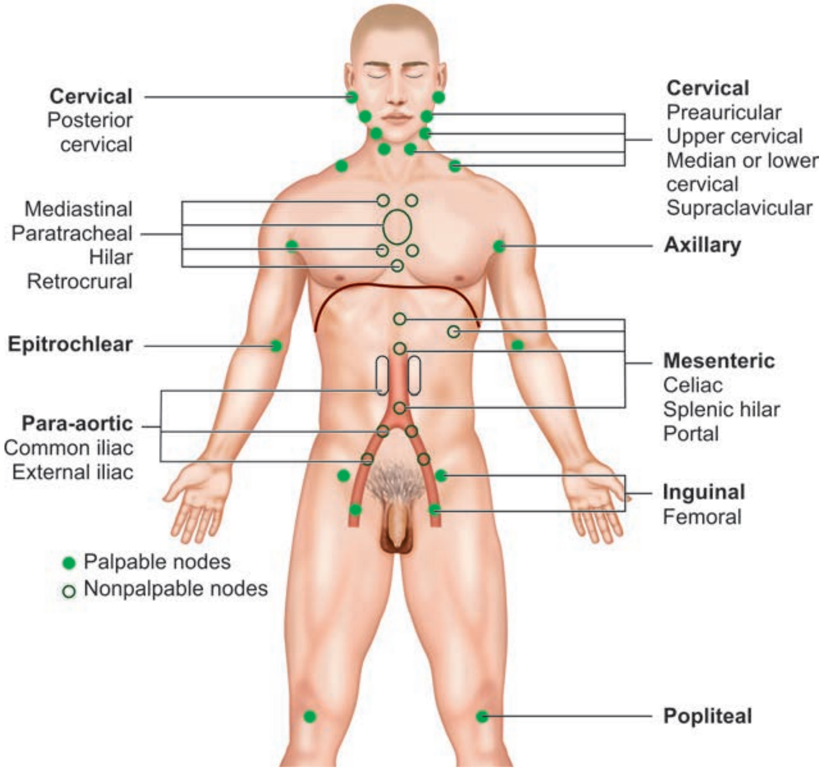
Clinical manifestation: Deficiency manifests as bleeding/hemorrhagic state.

GENERALIZED LYMPHADENOPATHY

Q. Discuss the differential diagnosis (causes) of generalized lymphadenopathy in an adult.

Q. Assessment of the extent of lymph nodal enlargement.

- Generalized lymphadenopathy is defined as significant enlargement of more than 2 or more noncontiguous lymph node groups. Various lymph node areas are depicted in **Figure 9.43**.
- Clinical examination of lymph nodes: (1) Sites of lymph node enlargement, (2) size, (3) consistency, (4) mobile/fixed, (5) presence or absence of tenderness, and (6) draining area.
- Systemic abnormalities if any.
- **Investigations:**
  - Chest X-ray and CT scan of thorax: To detect lymphadenopathy in the mediastinal, hilar, and paratracheal region.
  - Ultrasound scanning and CT scan of abdomen: To detect intra-abdominal lymph nodes.
  - Lymph node groups: Location, lymphatic drainage, and differential diagnosis are mentioned in **Table 9.65**.



Cervical
Posterior cervical
Mediastinal
Paratracheal
Hilar
Retrocrural
Epitrochlear
Para-aortic
Common iliac
External iliac
● Palpable nodes
○ Nonpalpable nodes
Cervical
Preauricular
Upper cervical
Median or lower cervical
Supraclavicular
Axillary
Mesenteric
Celiac
Splenic hilar
Portal
Inguinal
Femoral
Popliteal

FIG. 9.43: Lymph node areas.

TABLE 9.65: Lymph node groups: Location, lymphatic drainage, and differential diagnosis.

Location	*Lymphatic drainage*	*Causes*
Submandibular	Tongue, submaxillary gland, lips and mouth, conjunctivae	Infections of head, neck, sinuses, ears, eyes, scalp, pharynx
Submental	Lower lip, floor of mouth, tip of tongue, skin of cheek	Mononucleosis syndromes, Epstein–Barr virus, cytomegalovirus, toxoplasmosis
Jugular	Tongue, tonsil, pinna, parotid	Pharyngitis organisms, rubella, tuberculosis
Posterior cervical	Scalp and neck, skin of arms and pectorals, thorax, cervical, and axillary nodes	Tuberculosis, lymphoma, head and neck malignancy
Suboccipital	Scalp and head	Local infection
Postauricular	External auditory meatus, pinna, scalp	Local infection
Preauricular	Eyelids and conjunctivae, temporal region, pinna	External auditory canal
Right supraclavicular node	Mediastinum, lungs, esophagus	Lung (right lung and left lower lobe), retroperitoneal or gastrointestinal cancer, tuberculosis
Left supraclavicular node	Thorax, abdomen via thoracic duct	➢ Lymphoma, lung (left upper lobe) ➢ Carcinoma of bronchus, bowel (gastric), bladder, breast and testes, tuberculosis
Axillary	Arm, thoracic wall, breast, parietal pleura	Infections, cat-scratch disease, lymphoma, breast cancer, brucellosis, melanoma, tuberculosis
Epitrochlear	Ulnar aspect of forearm and hand	Infections, NHL, sarcoidosis, tularemia, cat-scratch disease secondary syphilis, disseminated tuberculosis, HIV
Inguinal	Penis, scrotum, vulva, vagina, perineum, gluteal region, lower abdominal wall, lower anal canal	Infections of the leg or foot, STDs (e.g., herpes simplex virus, gonococcal infection, syphilis, chancroid, granuloma inguinale, lymphogranuloma venereum), lymphoma, pelvic malignancy, bubonic plague

Differential Diagnosis (Box 9.31)

Castleman's disease, or angiofollicular lymph node hyperplasia

- Patients often present with a localized lymphoid mass, but some patients have a systemic illness with fevers, night sweats, weight loss, and fatigue.

- Frequently, the systemic symptoms of Castleman's disease are related to excessive production of IL-6.
- Castleman's disease in HIV-infected patients is frequently associated with HHV-8.
- Patients with disseminated and plasma cell–rich forms of Castleman's disease may occasionally progress to lymphoma.
- Patients with localized Castleman's disease can be treated with surgical removal or radiotherapy. Patients with systemic disease may respond to treatment with high-dose corticosteroids.

Sinus histiocytosis with massive lymphadenopathy, also known as Rosai–Dorfman disease

- Manifests as bulky lymphadenopathy in children and young adults.
- Extranodal sites such as the skin, upper airways, gastrointestinal tract, and CNS can be involved. There is a characteristic pattern of lymphoid proliferation with a thick fibrous capsule, distention of lymphoid sinuses, accumulation of plasma cells, and proliferation of large, often atypical histiocytes.
- The disease is usually self-limited, but it has been associated with autoimmune hemolytic anemia.

Kikuchi's disease (histiocytic necrotizing lymphadenitis)

- Disease of unknown origin that most commonly affects young women.
- Symptoms most commonly consist of painless cervical lymphadenopathy that is often accompanied by fever, flu-like symptoms, and rash.
- Sometimes associated with SLE. Treatment is symptomatic, and symptoms usually resolve within weeks or months.
- Lymph node biopsies reveal foci of necrotic histiocytes.

Box 9.31: Differential diagnosis of generalized lymphadenopathy.

Cause

- **Malignant neoplasms:**
  - Lymphomas (Hodgkin and non-Hodgkin)
  - Leukemias
    - Acute lymphoblastic leukemia
    - Chronic lymphocytic leukemia
    - Chronic myeloid leukemia in blast crisis
  - Metastatic disease (head and neck cancers, lung and breast cancers, GIT malignancies)
- **Infections:**
  - Disseminated tuberculosis
  - Human immunodeficiency virus (HIV) infection
  - Secondary syphilis
  - Infectious mononucleosis
  - Brucellosis
  - Local infections (cellulitis, pharyngitis)
  - Plague
  - Other infections: Toxoplasmosis, cytomegalovirus infection, hepatitis B, atypical mycobacteria, histoplasmosis, coccidioidomycosis, cryptococcosis
- **Autoimmune diseases:**
  - Systemic lupus erythematosus
  - Rheumatoid arthritis
- **Drugs induced** (phenytoin, allopurinol, hydralazine, primidone, quinidine)
- **Systemic disorders:** Amyloidosis, sarcoidosis, serum sickness, hyperthyroidism, Gaucher's disease, Kawasaki disease, Kimura disease, hemophagocytic lymphohistiocytosis
- **Rare:** Castleman's disease, Kikuchi-Fujimoto disease, Rosai–Dorfman disease

Kimura disease: Lymphadenopathy; peripheral eosinophilia; and elevated levels of serum immunoglobulin E (IgE).

HEMOSTASIS

Q. Discuss the mechanism of hemostasis.

Q. Write a short essay/note on platelets and their functions.

Components of Hemostasis

Three major components namely: (1) Platelet component, (2) vascular component (endothelium), and (3) coagulation component participate in normal hemostatic mechanism. The first two components are involved in primary hemostasis while the last component is involved in secondary hemostasis.

Coagulation System

Coagulation factors are listed in **Table 9.66**. Coagulation can be activated by two pathways namely *extrinsic* and *intrinsic* (**Fig. 9.44**). Both the pathways converge on the activation of factor X to produce factor Xa (activated X).

- **Extrinsic pathway:**
  - It requires an exogenous trigger; hence the name extrinsic. But now it is observed that released tissue factor (a protein-phospholipid complex normally present on vascular cells and activated monocytes) from vascular injury can initiate this pathway. It converts factor VII into activated factor VII (VIIa) in presence of calcium. Activated tissue factor VII complex activates factors IX and X.
  - The coagulation factors utilized in extrinsic pathway are factors VII, X, II, V, and fibrinogen.
  - **Prothrombin time (PT)** is the laboratory test which assesses the function of the coagulation factors involved in the extrinsic pathway.

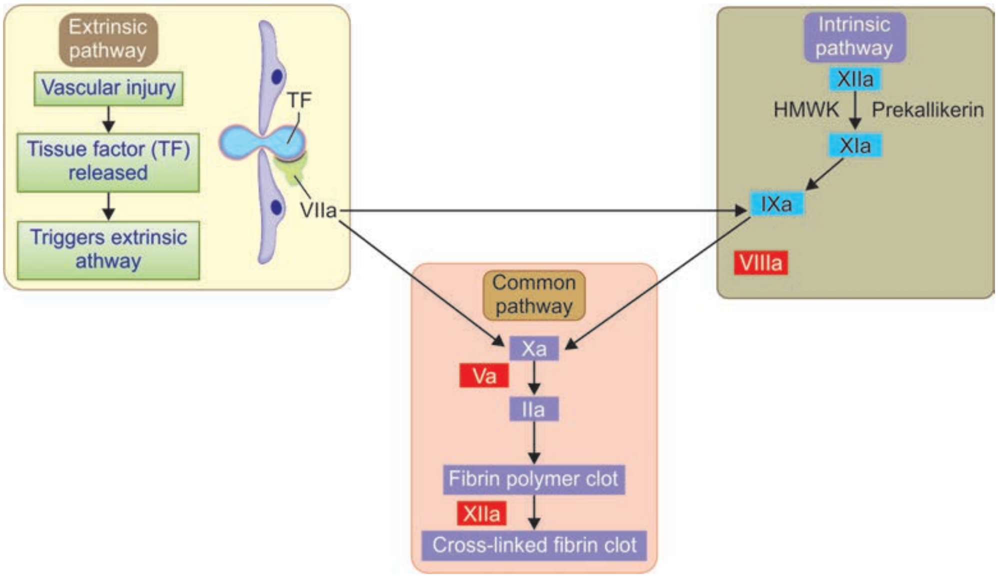


FIG. 9.44: Different pathways of coagulation (extrinsic, intrinsic, and common) pathways.

TABLE 9.66: Coagulation factors.

Factor	*Synonym*
I	Fibrinogen
II	Prothrombin
III	Thromboplastin
IV	Calcium
V	Proaccelerin
VI	No specific name or function
VII	Proconvertin
VIII	Antihemophilic factor
IX	Christmas factor
X	Stuart–Prower factor
XI	Plasma thromboplastin antecedent
XII	Hageman factor
XIII	Fibrin-stabilizing factor

- **Intrinsic pathway:**
    - This gets activated with exposure of prekallikrein, high-molecular weight kininogen, and factor XII (Hageman factor) to any thrombogenic (negatively charged) surfaces (including glass beads).
    - Prekallikrein is converted to kallikrein and factor XII becomes activated factor XII (XIIa).
    - Factor XIIa converts factor XI into XIa.
    - Factor XIa activates factor IX, and factor IXa with its cofactor FVIIIa activates X to Xa.
    - The coagulation factors utilized in the intrinsic pathway are, in order of reaction, factors XII, pre-K, HMWK, XI, IX, VIII, X, V, II, and fibrinogen.
    - The **partial thromboplastin time (PTT)** assesses the function of the coagulation factors utilized in the intrinsic pathway. PTT is initiated by adding negatively charged particles like ground glass.
- **Common pathway:**
    - Above two pathways have in common factors X, V, prothrombin and fibrinogen; and this part of the coagulation pathway is known as the common pathway.
    - Common pathway is initiated by factor Xa. Factor Xa converts prothrombin to thrombin (Factor IIa). This is facilitated by Va.
    - Factor IIa converts fibrinogen into fibrin and also activates factor XIII to XIIIa that cross links fibrin to fibrin polymers.

Mechanism of Hemostasis (Fig. 9.45)

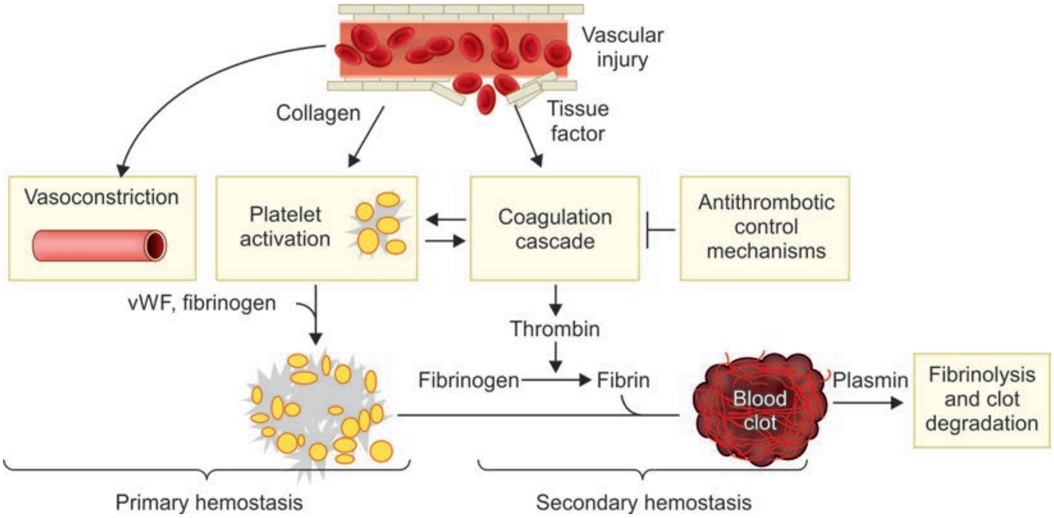
- **Primary hemostatic plug:** The platelet component undergoes three different events—platelet adhesion and shape change, platelet secretion (release of granule contents) and platelet aggregation.
- **Secondary hemostatic plug:**
    - Exposure of tissue factor at the site of injury activates the extrinsic coagulation system **(Box 9.32)**.
    - The process generates thrombin, which cleaves circulating fibrinogen into insoluble *fibrin*, creating a fibrin meshwork at the injured site.
    - The platelets contract and form an irreversibly fused mass known as secondary hemostatic plug.
    - The sequence of conversion of the initial temporary primary *hemostatic* (platelet) plug into a permanent secondary hemostatic plug is known as *secondary hemostasis*.

Coagulation Regulatory Mechanism

Coagulation regulatory mechanism has been shown in **Figure 9.46**.

Q. Briefly outline the natural inhibitors of coagulation.

The activated coagulation system must be limited to the site of vascular injury so as to prevent coagulation in the entire vascular system. This is achieved by three endogenous anticoagulants.



Vascular injury
Collagen
Tissue factor
Vasoconstriction
Platelet activation
Coagulation cascade
Antithrombotic control mechanisms
vWF, fibrinogen
Thrombin
Fibrinogen
Fibrin
Blood clot
Plasmin
Fibrinolysis and clot degradation
Primary hemostasis
Secondary hemostasis

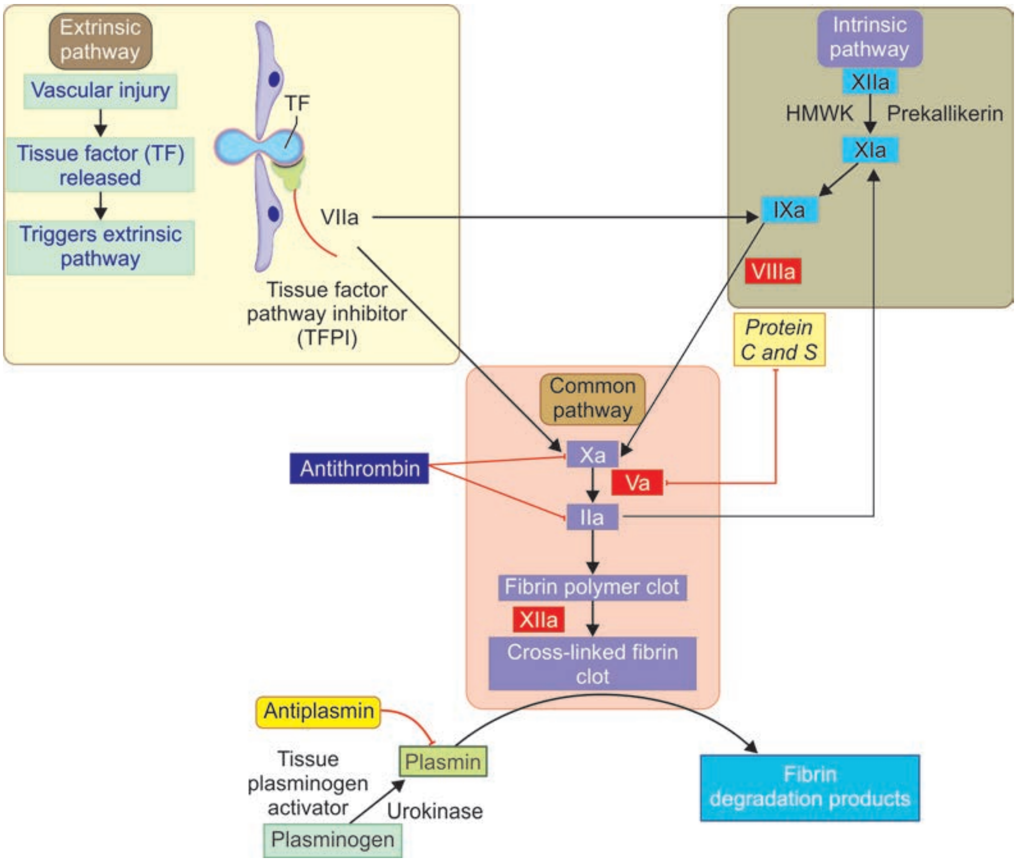
FIG. 9.45: Mechanism of hemostasis.

Box 9.32: Functions of platelets.

- Maintain vascular integrity
- Spontaneously arrest bleeding through platelet plug formation
- Participate in the intrinsic coagulation system
- Promote repair and healing through release of growth factors

Inhibitors of Coagulation

- **Antithrombin** is a circulating serine protease inhibitor (serpin) which inhibits the activity of thrombin and factors IXa, Xa, XIa and XIIa. One of these is antithrombin III which gets activated by binding to heparin-like molecules on endothelial cells. The heparin used to minimize thrombosis acts by activating antithrombin III.
- **Proteins C and S** are vitamin K-dependent proteins that act in a complex. Thrombin generated by activation of coagulation cascade, binds with thrombomodulin present



Extrinsic pathway
Vascular injury
Tissue factor (TF) released
Triggers extrinsic pathway
TF
VIIa
Tissue factor pathway inhibitor (TFPI)
Intrinsic pathway
XIIa
HMWK
Prekallikerin
XIa
IXa
VIIIa
Protein C and S
Common pathway
Antithrombin
Xa
Va
IIa
Fibrin polymer clot
XIIa
Cross-linked fibrin clot
Antiplasmin
Tissue plasminogen activator
Plasmin
Urokinase
Plasminogen
Fibrin degradation products

FIG. 9.46: Coagulation regulatory system consisting of antithrombin, protein C and S, and tissue factor pathway inhibitor.

on the endothelial cell membrane, and activates the coagulation regulatory system called protein C system. Activated protein C (APC) binds with protein S to form APC-protein S complex. This complex inactivates factors Va and VIIIa. Impaired activity of protein C as occurs in factor V Leiden produces thrombophilia.

- **Tissue factor pathway inhibitor (TFPI):** It is a protein which inactivates tissue factor—factor VIIa complexes and inactivates factor VIIa.
  Endothelial cells produce prostacyclin and nitric oxide which inhibit platelet aggregation.

Fibrinolytic System

Q. Describe the fibrinolytic system.

Activation of the coagulation also initiates the fibrinolytic system so that the size of the clot is limited. Fibrinolytic system does this by removal of fibrin from the clot. Otherwise, the clot may progress and involve the entire circulation with its consequences.

BLEEDING DISORDERS (HEMORRHAGIC DIATHESIS)

Q. Discuss the evaluation of a patient with bleeding disorder.

Definition

Increased tendency to hemorrhage (usually with insignificant injury) are collectively called as bleeding disorders (hemorrhagic diathesis). Broad classification of bleeding disorders is listed in **Box 9.33**.

Box 9.33: Broad classification of bleeding disorders.

- Coagulation defects
- Platelet disorders
- Vessel wall abnormalities

Evaluation/Investigation of Bleeding Disorders

History

Information to be obtained from the history to determine:

- Whether there is a generalized hemostatic defect?
  - Evidence includes bleeding from multiple sites, spontaneous bleeding, and excessive bleeding after injury.
- Whether the hemostatic defect is inherited or acquired?
  - Features of inherited defect: (1) A family history of a bleeding, (2) Age of onset: Severe inherited defects usually become apparent in infancy, while mild inherited defects are detected later in life and (3) Lifelong history.
  - Features of acquired defects: (1) Short duration and (2) Evidence of disease causing the defects. Examples, evidence of liver disease, renal failure, disseminated intravascular coagulation (DIC).
- Whether the bleeding pattern is suggestive of a vascular/platelet defect or a coagulation defect? Distinguishing features of bleeding in platelet, vascular, and coagulation disorders are shown in **Table 9.67**.

Q. PA21.3 Differentiate platelet from clotting disorders based on the clinical and hematologic features.

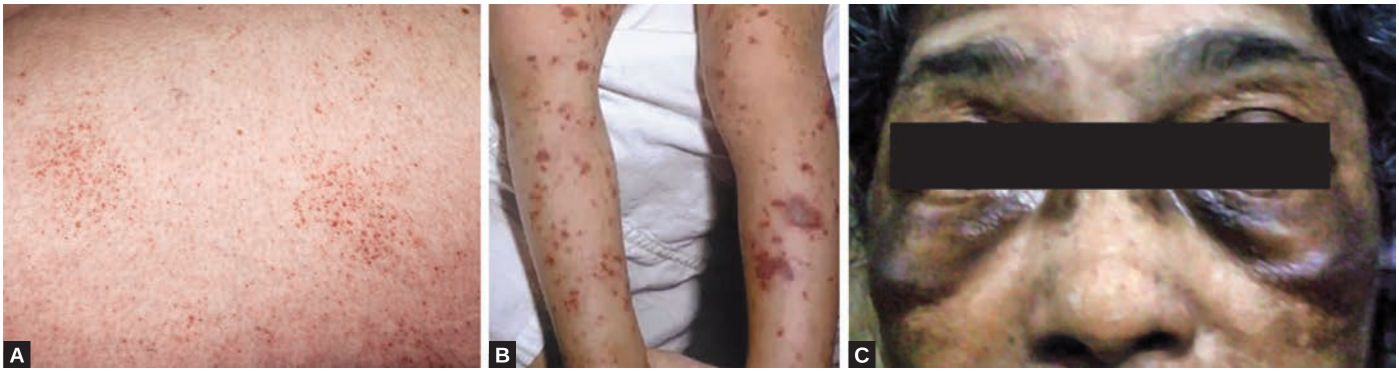
Physical Examination

Physical examination consists of search for the following:

- Type of lesions:
  - Purpura, bruises, ecchymoses.
  - Examination of joints, particularly knees, ankles, and elbows for hemarthrosis.
  - Scars over elbows and knees in factor XIII deficiency.
- Signs of liver cell disease

TABLE 9.67: Distinguishing patterns of bleeding in platelet, vascular, and coagulation disorders.

Characteristics	*Platelet/vascular disorders*	*Coagulation disorders*
Onset	Spontaneous and develops immediately after trauma/surgery	Delayed bleeding after trauma/surgery
Type of lesion	Petechiae **(Fig. 9.47A)**, purpura **(Fig. 9.47B)**, ecchymosis **(Fig. 9.47C)**	Hematomas
Sites	Skin, mucous membrane	Deep tissues
Mucous membrane	Common from nose, mouth, gastrointestinal and genitourinary tracts	Uncommon except from gastrointestinal or genitourinary tract
Into the joint	Absent	Common in severe factor deficiencies
Into the muscle	Following trauma	Spontaneous
Local pressure	Effective	Ineffective



[redacted]

FIGS. 9.47A TO C: (A) Petechiae which appear as small (1–2 mm in diameter), red to purple hemorrhagic spots in the skin, mucous membranes or serosal surfaces; (B) Purpura—slightly larger (>3 mm) than petechiae; (C) Ecchymoses are larger (>1–2 cm) and result from blood escaping.

TABLE 9.68: Screening tests used in bleeding disorders.

Name of the test	***Evaluation***
Blood count and film	Show the number and morphology of platelets and any blood disorder
Platelet count (Normal count: 150 to 450 × 10^9/L)	Platelets
Bleeding time (Normal: <9 minutes)	Platelets
Prothrombin time (Normal: 12–14 seconds)	Platelet function, von Willebrand factor
Activated partial thromboplastin time (Normal: 33–45 seconds)	Extrinsic pathway, factors II, V, VII, X
Thrombin time (Normal: 3–5 second > control)	Intrinsic pathway, factors II, V, VIII, IX, X, XI, XII
Clot retraction	Common pathway, factors I, II
Fibrinogen concentration	Platelets
Fibrin degradation products (FDPs)	Fibrinogen

- Neurological signs
- Hepatosplenomegaly and lymphadenopathy.

Laboratory Investigations

Q. Write a short note on screening tests for hemostasis/bleeding disorders.

Screening tests used in bleeding disorders have been shown in **Table 9.68.**

- **Bleeding time**
  - Normal range: 4–9 minutes.
  - Prolonged in platelet disorders.
- **Prothrombin time**

Q. Write a short note on prothrombin time.

  - It is measured by adding tissue factor (thromboplastin) and calcium to the patient's plasma.
  - Normal is 12–16 seconds
  - Measures VII, X, V, prothrombin, and fibrinogen (classic "extrinsic" pathway)
  - Prolonged
    - With abnormalities of above factors (II, V, VII, and X)
    - In liver disease, DIC, vitamin K deficiency and if the patient is on oral warfarin therapy.
- **Activated partial thromboplastin time (APTT)**
  - Also known as the PTT and is performed by adding a surface activator (such as kaolin, micronized silica or ellagic acid) phospholipid (to mimic platelet membrane) and calcium to the patient's plasma.
  - Normal APTT is 26–37 seconds
  - APTT measures XII, XI, IX, VIII, X, V, prothrombin, and fibrinogen (classic "intrinsic" pathway).
  - **Causes of prolonged APTT**
    - With deficiencies of one or more of above factors (II, V, VIII, IX, X, XI and XII including hemophilia A and B, von Willebrand disease)
    - DIC, heparin therapy, and presence of lupus anticoagulant and acquired factor inhibitors.

- **Correction tests/mixing studies:** It may be used to differentiate various causes of prolonged PT, APTT, and TT
    - Prolonged PT, APTT or TT due to coagulation factor deficiencies can be corrected by addition of normal plasma to the patient's plasma.
    - Failure to correct after addition of normal plasma indicates the presence of an inhibitor of coagulation.
- **Factor assays:** It confirms coagulation defects.

Special tests of coagulation

To confirm the precise hemostatic defect and includes estimation of fibrinogen and FDPs. Various laboratory tests in bleeding disorders are presented in **Table 9.69**.

TABLE 9.69: Laboratory tests in various bleeding disorders.

Disorder	*PT*	*APTT*	*Platelets*	*Bleeding time*
Vit K deficiency	Prolonged	Prolonged	Normal	Normal
vWF dz	Normal PT	Prolonged	Normal	Prolonged/normal
DIC	Prolonged	Prolonged	Reduced	Prolonged
ITP	Normal	Normal	Reduced	Prolonged
Aplasia and leukemia	Normal	Normal	Reduced	Prolonged
Factor VII deficiency	Prolonged	Normal	Normal	Normal
Factor VIII deficiency (Hemophilia A)	Normal	Prolonged	Normal	Normal
Factor IX deficiency (Hemophilia B)	Normal	Prolonged	Normal	Normal
Factor XI, XII deficiency	Normal	Prolonged	Normal	Normal
Factor XIII deficiency (bleeding especially from umbilicus)	Normal	Normal	Normal	Normal

(PT: Prothrombin time; APTT: Activated partial thromboplastin time; vWF: von Willebrand factor; DIC: Disseminated intravascular coagulation; ITP: Immune thrombocytopenic purpura)

DISORDERS OF PLATELETS

THROMBOCYTOPENIA

Q. Define thrombocytopenia. Enumerate the common causes, clinical manifestations, investigations, and management of thrombocytopenia.

Definition

Decrease in the platelet count below the lower limit of 150,000/μL is known as thrombocytopenia.

Causes of thrombocytopenia are given in **Table 9.70**.

General Clinical Manifestations

- **Bleeding into skin:** It presents as purpura, petechiae, ecchymoses.
- **Bleeding into mucous membranes:** It presents as epistaxis, hemorrhagic bullae in oral mucosa, genitourinary bleeding, and gastrointestinal bleeding.

TABLE 9.70: Causes of thrombocytopenia.

Increased platelet destruction	*Decreased production of platelets*
Immune mediated ➢ **Primary:** Idiopathic thrombocytopenic purpura—acute and chronic ➢ **Secondary:** – Autoimmune: Systemic lupus erythematosus – Alloimmune: Post-transfusion or during pregnancy – Drugs: Quinidine, heparin, sulpha compounds – Infections: HIV, infectious mononucleosis, cytomegalovirus **Nonimmune mediated** ➢ Disseminated intravascular coagulation ➢ Thrombotic thrombocytopenic purpura ➢ Hemolytic uremic syndrome ➢ Mechanical destruction ➢ Microangiopathic hemolytic anemias	**Generalized diseases of bone marrow** ➢ **Aplastic anemia:** Congenital, acquired ➢ **Marrow infiltration:** Leukemia, disseminated cancer **Selective impairment of platelet production** ➢ **Drugs:** Alcohol, thiazides, cytotoxic drugs, alcohol ➢ **Infections:** Measles, HIV **Ineffective megakaryopoiesis** ➢ Megaloblastic anemia ➢ Myelodysplastic syndromes
Sequestration	**Dilutional**
Hypersplenism: Portal hypertension, lymphomas, myeloproliferative disorders	

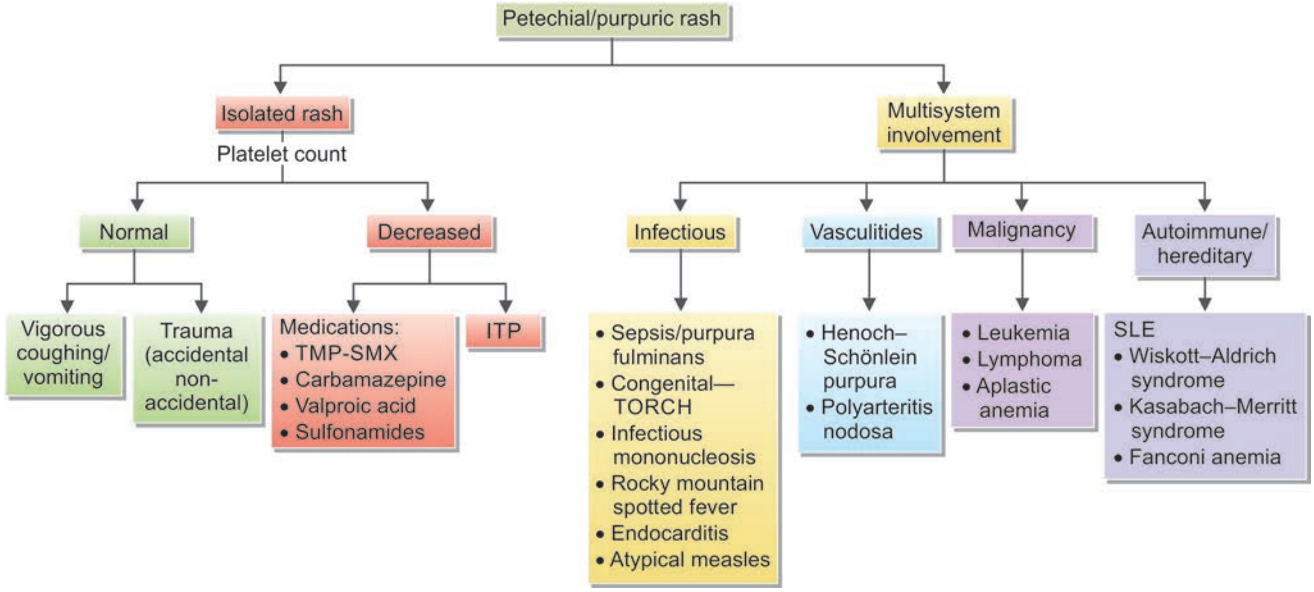
- Severe thrombocytopenia produces fundal hemorrhage and intracranial bleeding **(Table 9.71)**.

Approach to the differential diagnosis for petechiae/purpura is presented in **Flowchart 9.4**.

TABLE 9.71: Clinical features associated with decreased platelet count.

Platelet count/μL	***Clinical features***
30,000–50,000	Post-traumatic bleeding
<30,000	Spontaneous bleeding
<10,000	Intracranial bleeding

FLOWCHART 9.4: Approach to the differential diagnosis for petechiae/purpura.



Petechial/purpuric rash
Isolated rash
Platelet count
Normal
Decreased
Vigorous coughing/ vomiting
Trauma (accidental non-accidental)
Medications:
• TMP-SMX
• Carbamazepine
• Valproic acid
• Sulfonamides
ITP
Multisystem involvement
Infectious
Vasculitides
Malignancy
Autoimmune/ hereditary
• Sepsis/purpura fulminans
• Congenital—TORCH
• Infectious mononucleosis
• Rocky mountain spotted fever
• Endocarditis
• Atypical measles
• Henoch–Schönlein purpura
• Polyarteritis nodosa
• Leukemia
• Lymphoma
• Aplastic anemia
SLE
• Wiskott–Aldrich syndrome
• Kasabach–Merritt syndrome
• Fanconi anemia

(ITP: Immune thrombocytopenic purpura; TMP-SMX: Trimethoprim-sulfamethoxazole; SLE: Systemic lupus erythematosus)

Laboratory Investigations

- **Platelet count**: Reduced and clinical manifestations roughly correlate with the platelet count.

- **Hess test** (capillary fragility test/tourniquet test) may be positive
  - **Principle:** It measures the ability of capillaries to withstand the increased stress.
  - **Procedure:**
    - Sphygmomanometer cuff is tied to the upper arm above the elbow and the cuff is inflated to 80 mm Hg for 5 minutes.
    - Release the pressure after 5 minutes.
    - The number of petechiae present in a circle of 5 cm diameter on the flexor aspect of the forearm (below the bend of the elbow) is noted.
  - **Normal:** 0–5 petechiae.
  - **Interpretation:** Positive test is indicated by more than 10 petechiae and is observed in:
    - Vascular purpura
    - Defective platelet function
    - Thrombocytopenia
    - Scurvy

Bleeding time (BT): Prolonged, and it bears a close relationship to platelet count.

- **Bone marrow:**
  - Normal or increased number of megakaryocytes indicates increased platelet destruction, hypersplenism, or ineffective platelet production.
  - Decreased number of megakaryocytes indicates reduced production of platelets.

Qualitative Platelets Defects

Qualitative defects of platelet function can be hereditary/congenital or acquired **(Box 9.34 and Fig. 9.48)**.

Box 9.34: Classification of platelet function disorders.

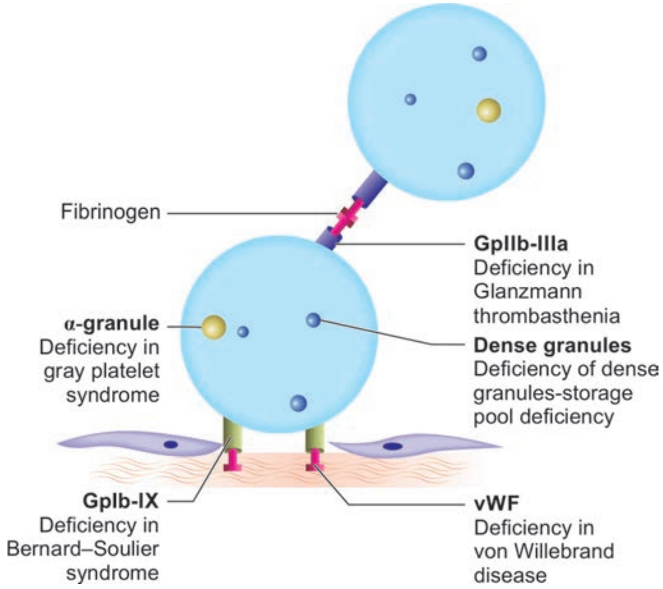
A. Hereditary
- **Disorders of platelet adhesion**
  - Bernard–Soulier syndrome
- **Disorders of platelet secretion**
  - Storage pool deficiency
- **Disorders of platelet aggregation**
  - Glanzmann thrombasthenia

B. Acquired
- Drugs: Aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs), dipyridamole, sulfinpyrazone
- Renal failure (uremia)
- Hematologic malignancies: Myeloproliferative and myelodysplastic disorders

Immune Thrombocytopenic Purpura

Definition

Immune (idiopathic) thrombocytopenic purpura (ITP) is an autoimmune disorder characterized by increased destruction of platelets by **autoantibodies directed against platelet membrane GPIIb/IIIa and GPIb/IX.**



Fibrinogen
GpIIb-IIIa
Deficiency in Glanzmann thrombasthenia
α-granule
Deficiency in gray platelet syndrome
Dense granules
Deficiency of dense granules-storage pool deficiency
GpIb-IX
Deficiency in Bernard–Soulier syndrome
vWF
Deficiency in von Willebrand disease

FIG. 9.48: Qualitative/functional disorders of platelets.

Pathogenesis

Q. PA21.2 Classify and describe the etiology, pathogenesis and pathology of vascular and platelet disorders including ITP.

Q. PE29.6 Discuss the cause of thrombocytopenia in children: Describe the clinical features and management of Idiopathic Thrombocytopenic Purpura (ITP).

- ITP is *an autoimmune* disorder with formation of antiplatelet antibodies, directed against membrane glycoproteins most often IIb/IIIa or Ib/IX of platelets.
- The antiplatelet antibodies can be demonstrated in approximately 80% of patients and are of the IgG type.

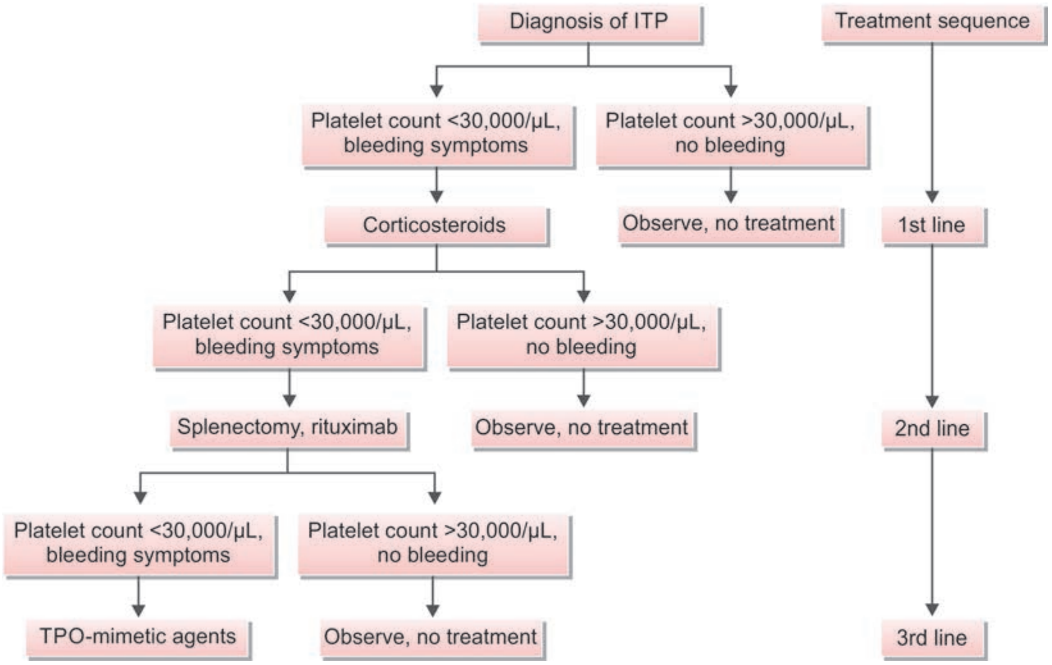
Clinical Features

ITP can be primary or secondary:
- **Primary:** Most cases are primary. There are two major subtypes of primary ITP, acute and chronic **(Table 9.72)**.
  - Acute form is more common in children
  - Chronic form is characterized by the persistence of thrombocytopenia for more than 6 months and is more common in adults.
- **Secondary:** Observed in several diseases such as systemic lupus erythematosus, acquired immunodeficiency syndrome (AIDS), hepatitis C, following viral infections and as a complication of drug therapy.
  - Clinical features are not specific but are due to thrombocytopenia in general.
  - Patient has no physical signs other than those due to bleeding and anemia (following menorrhagia and epistaxis), intracranial hemorrhage (ICH), overt gastrointestinal bleeding, and hematuria, are uncommon.

TABLE 9.72: Differences between clinical features of idiopathic thrombocytopenic purpura in children (acute) and adults (chronic).

	Children	**Adults**
	Occurrence	
Peak age (years)	2–4	15–40
Sex (F:M)	Equal	1.2–1.7
	Presentation	
Onset	Acute (<1 week)	Insidious >2 months
Symptoms	Purpura (<10% with severe bleeding)	Purpura (typically bleeding not severe)
Platelet count	Most <20,000/L	Most <20,000/L
Antecedent infection	Usually follows an antecedent upper respiratory viral infection	Usually no preceding history of viral infection
	Course	
Spontaneous remission	83%	2%
Chronic disease	24%	43%
Response to splenectomy	71%	66%
Eventual complete recovery	89%	64%
	Morbidity and mortality	
Cerebral hemorrhage	<1%	3%
Hemorrhagic death	<1%	4%
Mortality of chronic refractory disease	2%	5%

FLOWCHART 9.5: Diagnosis of immune thrombocytopenic purpura (ITP).



Diagnosis of ITP
Treatment sequence
Platelet count <30,000/μL, bleeding symptoms
Platelet count >30,000/μL, no bleeding
Corticosteroids
Observe, no treatment
1st line
Platelet count <30,000/μL, bleeding symptoms
Platelet count >30,000/μL, no bleeding
Splenectomy, rituximab
Observe, no treatment
2nd line
Platelet count <30,000/μL, bleeding symptoms
Platelet count >30,000/μL, no bleeding
TPO-mimetic agents
Observe, no treatment
3rd line

- Splenomegaly and lymphadenopathy are uncommon in primary ITP and in their presence one should consider the diagnoses other than ITP.
- May be associated with hemolysis **(Evan's syndrome)**.
- Majority of patients with acute ITP recover within 6 months.

Investigations and Diagnosis

The diagnosis of ITP is one of exclusion. It requires only isolated thrombocytopenia (i.e., without anemia or leukopenia) without another apparent cause **(Flowchart 9.5)**.

- **Platelet count** is usually **markedly reduced** (thrombocytopenia) and is below 80 × 10^9/L. Platelet count should be repeated using sodium citrate (anticoagulant) to exclude pseudothrombocytopenia caused by platelet aggregation and clumping in the presence of EDTA anticoagulant.
- **Tourniquet test (Hess test):** Positive
- **Bleeding time (BT):** Prolonged
- **Bone marrow examination:** Usually not performed in acute ITP, unless treatment becomes necessary on clinical grounds. It is important in chronic ITP to rule out thrombocytopenia resulting from bone marrow failure. Bone marrow shows moderate increase in number of both immature and mature forms of megakaryocytes. A decrease in the number of megakaryocytes argues against the diagnosis of ITP.
- **Antiplatelet antibodies:** Tests for platelet autoantibodies are not widely available but may be demonstrated in blood. However, a negative test does not exclude ITP.
- In chronic ITP, secondary causes such as HIV, hepatitis C virus infection, etc., should be excluded.

Treatment

- Children with mild acute ITP usually do not require treatment
- Adults with platelet counts >30 × 10^9/L usually do not require treatment. Patients with even lower platelet counts may require treatment, if they have spontaneous bruising or bleeding
- Indications for treatment:
  - Overt hemorrhage (treated with platelet concentrates)
  - Platelet counts below 20,000/mm^3
  - Organ or life-threatening bleeding irrespective of the circulating platelet count
- **Platelet transfusion:** If platelet counts <20,000/mm^3 or bleeding manifestations

- **Single-donor platelets** have a shelf life of 3–5 days, and one unit will raise platelets 30,000–50,000/μL
- **First-line therapy:** Consists of treatment with **oral corticosteroids**
  - Indications for corticosteroids:
    - To induce remission
    - To maintain remission in chronic ITP
    - Postoperatively, in patients where splenectomy failed to achieve the result
    - Pregnant women after the 5th month of pregnancy
  - Dosage of corticosteroids:
    - Both adults and children: Initial dose is 1–2 mg/kg of prednisolone/day. Initial dose is continued for at least 2 weeks (or if necessary 3–4 weeks), and then reduced slowly and stopped
    - About 66% respond to prednisolone but relapse is common when the dose is reduced
- **Second-line therapy:**

  Splenectomy: Majority of patients respond well and achieve a normal platelet count
  - **Indications of splenectomy:**
    - Chronic ITP in adults who fail to respond to corticosteroids
    - Patients requiring unacceptably high doses of corticosteroids to maintain a safe platelet count
    - When there is severe bleeding or threatening cerebral hemorrhage (despite adequate corticosteroid therapy)
    - In the first 4–5 months of pregnancy, if steroids do not induce full remission
  - **Mechanism of action of splenectomy:**
    - Spleen being the major site of platelet destruction, splenectomy prevents its destruction
    - Reduces the concentration of circulating antiplatelet antibodies

  Rituximab:
  - 375 mg/m^2 intravenously once a week for four consecutive weeks
  - ADR-immunosuppression, progressive multifocal leukoencephalopathy
- **Third-line therapy:**

  Patients who fail to respond to splenectomy, a wide range of other therapies are available. Major drawbacks of these therapies are modest response rates and slow onset of action. The therapies include:
  - **High-dose corticosteroids**
  - **Intravenous immunoglobulin** (i.e., IgG): It is effective. Responses are only transient (3–4 weeks)
    - Indications:
      - ☐ Acute situation prior to surgery and childbirth, and in patients with intracranial bleed
      - ☐ Patients with ITP where corticosteroid therapy and splenectomy are contraindicated
    - Side effects: Nausea, vomiting, fever, and headache. Uncommonly neutropenia and hemolytic anemia
    - Dose: 1–2 g/kg
  - **RhO(D) immune globulin (anti-D)**
    - Indications: Patients who do not respond to steroids and may be tried before splenectomy
    - Should be given only to Rh-positive patients
    - Effective in patients with ITP but the effect is usually temporary, and nearly 50–75% patients relapse
    - Dose is 75 μg/kg intravenously
    - Side effects: Nausea, vomiting, fever, chills and intravascular hemolysis
  - **Immunosuppressive therapy**
    - Indications:
      - ☐ Refractory cases which fail to respond to corticosteroids and splenectomy
      - ☐ Patients with ITP where corticosteroid therapy and splenectomy are contraindicated
    - Agents used are vinca alkaloids (vincristine, vinblastine), azathioprine, cyclophosphamide, cyclosporine, and combination chemotherapy, mycophenolate mofetil
  - **Plasmapheresis:** Employed as an emergency measure to remove antibodies from the plasma
  - **Thrombopoietin (TPO) mimetic drugs:**
    - **Romiplostim,** 500 μg subcutaneously once weekly
    - **Eltrombopag** 50 mg, once-daily pill
    - **Avatrombopag** once-daily pill
      - ☐ Serious ADRs: Thrombocytosis, thrombosis, bone marrow fibrosis
  - **Fostamatinib:** A tyrosine kinase inhibitor that inhibits the spleen tyrosine kinase (SYK)

- Others:
  - Danazol is an androgen with low virilizing activity has been tried in idiopathic thrombocytopenic purpura
  - Dapsone
  - Platelet transfusions are reserved for intracranial or other extreme hemorrhage, where emergency splenectomy may be justified
- **Emergency treatment:** Necessary in case of life-threatening bleeding. It consists of intravenous administration of methylprednisolone (30 mg/kg, maximum dose 1 g) over 20–30 minutes along with platelet transfusion. This is followed by intravenous immunoglobulin (1 g/kg)

Thrombocytosis

Q. What are the common causes of thrombocytosis?

Definition

Platelet count more than 450,000/mm^3 is known as thrombocytosis.

Causes

Causes of thrombocytosis have been shown in **Table 9.73**.

TABLE 9.73: Causes of thrombocytosis.

Idiopathic/primary (autonomous production)	*Secondary (reactive thrombocytosis)*
➢ Myeloproliferative neoplasms – Essential thrombocytosis – Polycythemia vera – Chronic myeloid leukemia ➢ Myelodysplastic syndrome	➢ Iron deficiency ➢ Malignancy (paraneoplastic feature) ➢ Following hemorrhage: Acute or chronic blood loss ➢ Following splenectomy ➢ Following major surgery ➢ Inflammatory disorders, e.g., rheumatoid arthritis and inflammatory bowel disease

DISORDERS OF COAGULATION (CLOTTING)

Q. Write a short note on congenital bleeding disorders.

Hereditary coagulation disorders are listed in **Box 9.35**.

Box 9.35: Hereditary coagulation disorders.

- von Willebrand disease
- Hemophilia A
- Hemophilia B
- Hemophilia C: Inherited deficiency of factor XI (factor 11); also called Rosenthal syndrome; an autosomal recessive disorder

Hemophilia A (Factor VIII Deficiency)

Q. PE29.7, PA21.2 Classify and describe the etiology, pathogenesis and pathology of vascular and platelet disorders including hemophilias.

Hemophilia A is the most common hereditary X-linked recessive disease with a reduction in the amount or activity of factor VIII (antihemophilic factor). About 30% of hemophiliacs have no family history and may be due to acquired mutations.

- Males are affected and females are carriers.
- Incidence: 1 in 10,000 males.

Mode of Inheritance

- Hemophilia A is an X-linked recessive disorder.
- Usually males are the sufferers and females are the carriers.
- Females can be hemophilic if:
  - She is born to an affected father and a carrier mother (25% risk).
  - Females with inactivation of the X-chromosome such as Turner's syndrome (45, XO)
  - She has inactivation of normal X-chromosome due to unfavorable lyonization (rare).
- Degree of deficiency of factor VIII and severity of bleeding tends to be similar in all the affected members of the same family.
- Normal level of factor VIII in the blood is 0.50–1.50 IU/mL. Hemophilia A may be classified based on the factor VIII activity in blood.

TABLE 9.74: Clinical classification of hemophilia A.

Classification	*Factor VIII level*	*Clinical features*
Mild	6–30% of normal (0.06–0.30 U/mL)	➢ Hemorrhage secondary to trauma or surgery ➢ Rare spontaneous hemorrhage
Moderate	1–5% of normal (0.01–0.05 U/mL)	➢ Hemorrhage secondary to trauma or surgery ➢ Occasional spontaneous hemarthrosis
Severe	≤1% of normal (≤ 0.01 U/mL)	➢ Spontaneous hemorrhage from early infancy ➢ Frequent spontaneous hemarthrosis and other hemorrhages, requiring clotting factor replacement

Clinical Features

- Clinical severity depends on the level of factor VIII activity and is presented in **Table 9.74**.
- Excessive bleeding: Hemophilia A is characterized by excessive bleeding, but is unusual until the child is about 6 months old.
- Post-traumatic bleeding: Bleeding following trauma is characteristically "delayed."

- Severity of bleeding: Range from mild to severe.
- Petechiae observed in platelet and vascular disorders are not seen in hemophilia.

Bleeding into joints (hemarthrosis)

- Frequent and spontaneous hemorrhages occur into the large joints, especially knees, elbows, ankles, wrists and hips, and are known as hemarthrosis.
- Nature of bleeding: Usually spontaneous or follows minor trauma.
- Acute stage: Affected joint is swollen, hot and tender and movements severely restricted. These changes gradually subside over a period of days.
- Consequences: Recurrent bleeding into the joints will lead to crippling deformities and disuse atrophy of muscles around the joint.

Bleeding into muscles

- Common sites: Calf and psoas muscles.
- Consequences:
    - Psoas hematomas may compress the femoral nerve resulting in sensory disturbances over thigh and weakness of quadriceps.
    - Calf hematomas can result in contraction and shortening of the Achilles tendon.

Other manifestations

- Easy bruising
- Massive bleeding following trauma (from wounds) or operative procedures (e.g., bleeding from sockets after dental extraction)
- Cerebral hemorrhage
- Hematuria and ureteric colic due to passage of blood clots.

Laboratory Investigations

- **Bleeding time is normal.**
- **Clotting time is prolonged.**
- **Platelet count is normal.**
- **PT is normal.**
- **APTT is increased** (normal 35–45 seconds) from 50 seconds to a few minutes.
- **Factor VIII assay** is required for the confirmation of diagnosis and to assess the factor VIII levels and severity of disease.

Antenatal Diagnosis

- **Chorionic villous sampling (CVS):** Done at 8–9 weeks of gestation, sexing the fetus, and using informative factor VIII probes. It is the preferred method.
- **Amniocentesis:** Sexing the fetus at 16 weeks of gestation by amniocentesis and, if the fetus is male, a fetal blood sampling is done at about 19–20 weeks of gestation.

Management

- **Local treatment**
    - **Wounds and bleeding from mucous membrane:** Apply local pressure and pressure bandages or sutures. Immobilize wounds by bandages, splinting, etc.
    - **Hematomas and hemarthrosis:**
        - **During acute stage:** Elevate the affected part and immobilize by splinting and bandages. Pain is relieved by analgesics like acetaminophen or codeine.
        - **During recovery phase:** Physiotherapy.
- **Replacement therapy**
    - Agents used: **Factor VIII concentrate** is available as plasma-derived and recombinant products. Recombinant products are the treatment of choice and are replacing the plasma-derived factor VIII concentrate **(Table 9.75)**.
    - Route of administration: Intravenous infusion to correction of deficiency of factor VIII and to achieve normal levels.
    - **Indications of replacement therapy:**
        - Early treatment of spontaneous bleeding.
        - Severe or prolonged wound and tissue bleeding.
        - Control of bleeding during and after surgery and trauma.

    - Prophylaxis: In all patients with severe hemophilia so as to prevent recurrent bleeding into joints and subsequent joint damage (arthropathy).
  - Calculation of dose: Plasma factor VIII, 1 unit/kg will increase activity by 2% (0.02 IU/mL). The desired factor VIII level is about 50% (presuming the initial level to be 0). The dose is calculated as:
    - Dose of factor VIII = Desired factor level (%) × body weight (in kg) × 0.5.
  - **Complications of replacement with factor VIII concentrate therapy:** Former replacement therapy with clotting factor concentrates prepared from pooled human plasma has led to other diseases in patients receiving such treatment.
    - Viral hepatitis (hepatitis B virus, delta virus and hepatitis C virus).
    - Infection with HIV.
    - Development of factor VIII inhibitors.
- **Non-transfusion therapy in hemophilia**
  - **DDAVP (1-desamino-8-D-arginine-vasopressin)**
    - Desmopressin (DDAVP) is a synthetic vasopressin analog that causes a transient rise in factor VIII activity by 3–5 times. It is given at a dose of 0.3 µg/kg body intravenously over 15 minutes.
    - Indication: Minor bleeding and minor surgery.
  - **Antifibrinolytic drugs**
    - Indications: To control local hemostasis/bleeding in the gums, nasal bleeding, gastrointestinal tract, during oral surgery (e.g., dental extraction) and menstruation.
    - Drugs used: **Epsilon (ε) aminocaproic acid (EACA) and tranexamic acid.**
    - **Action:** Inhibit the proteolytic activity of plasmin and results in inhibition of fibrinolysis.
    - Dose:
      - ❑ Tranexamic acid: 25 mg/kg three to four times a day.
      - ❑ EACA: Requires a loading dose of 200 mg/kg (maximum of 10 g) followed by 100 mg/kg per dose (maximum 30 g/d) every 6 hours.
    - Contraindication:
      - ❑ Not indicated to control hematuria because of the risk of formation of an occlusive clot in the lumen of genitourinary tract structures.
      - ❑ DIC.
      - ❑ Thromboembolic disease.

TABLE 9.75: Doses of factor VIII for treatment of hemorrhage.

Site of hemorrhage	*Desired factor VIII level (% of normal)*	*Factor VIII dose (U/kg body weight)*	*Frequency of dose (every no. of hours)*	*Duration (days)*
Hemarthrosis	30–50	~25	12–24	1–2
Superficial intramuscular hematoma	30–50	~25	12–24	1–2
Gastrointestinal tract	~50	~25	12	7–10
Epistaxis	30–50	~25	12	Until resolved
Oral mucosa	30–50	~25	12	Until resolved
Hematuria	30–100	~25–50	12	Until resolved
Central nervous system	50–100	50	12	At least 7–10 days
Retropharyngeal	50–100	50	12	At least 7–10 days
Retroperitoneal	50–100	50	12	At least 7–10 days

Complications

About 15% of the patients receiving factor VIII therapy develop inhibitory antibodies that bind and inhibit factor VIII.

- **Treatment for patients with factor VIII inhibitors:** Immune tolerance induction (ITI) is the most effective strategy of eradication of inhibitors with steroids or other immunosuppressants. Emicizumab, a bifunctional monoclonal antibody that can substitute for factor VIII is used in these cases.
- **Antibodies to AHG may occur de novo in non hemophiliacs as part of an immunological disorder such as systemic lupus erythematosus.**
- Chronic complications
  - ■ Arthropathy
  - ■ HIV and HCV infection
  - ■ Inhibitor development.

Preventive Therapy for Hemophilia

- Gene therapy
- Concizumab-monoclonal antibody directed against tissue factor pathway inhibitor

Hemophilia B

Q. Write a short essay/note on hemophilia B (Christmas disease) and its management.

- Hemophilia B is caused by a deficiency of factor IX.
- Mode of inheritance: X-linked disorder
- Clinical features: Similar to hemophilia A.
  - Patients with severe disease: Present with muscle hematomas and hemarthrosis which progresses to crippling joint deformities.
- Diagnosis: Factor IX assay shows deficiency of factor.

Management

Management is similar to hemophilia A.

- Replacement therapy:
  - Fresh frozen plasma to treat mild-to-moderate bleeding.
  - Recombinant factor IX: To treat moderate-to-severe bleeding.
    - Gene therapy: It may be effective in managing severe disease.
    - Desmopressin is ineffective.

von Willebrand's Disease

Q. Discuss the etiology, clinical features, investigations, and treatment of von Willebrand's disease.

- von Willebrand's disease (vWD) is characterized by defective platelet function as well as factor VIII deficiency, and both are due to a deficiency or dysfunction of vWF.
- **Major categories:** The vWF gene is located on chromosome 12 and numerous mutations of the gene produce vWD.
  - **Quantitative deficiency in vWF:**
    - Type 1 is an autosomal dominant, relatively mild disorder.
    - Type 3 is an autosomal recessive disorder and is severe.
  - **Qualitative defects (dysfunction) in vWF:** Type 2 von Willebrand disease accounts for 25% of all cases and is usually an autosomal dominant disorder. There are several subtypes.
    - Type 2a is most commonly characterized by defective assembly of multimers.
    - Type 2b is caused by synthesis of an abnormal vWF with increased affinity for platelets which results in thrombocytopenia.

von Willebrand Factor (Fig. 9.49)

- vWF is a protein synthesized by endothelial cells and megakaryocytes.
- **Main functions:**
  - vWF acts as a **carrier protein** which binds to **factor VIII** and forms plasma factor VIII-vWF complex. vWF protects factor VIII and is important for its stability. It has no role in the coagulation cascade, but deficiency of vWF causes a secondary reduction of factor VIII causing coagulation defect.
  - vWF is the most important cofactor for adhesion of platelets to the exposed subendothelial collagen matrix by GpIb/IX. Hence, the deficiency of vWF results in a defect of platelet function.

Clinical Features

- Variable and ranges from mild asymptomatic conditions to a severe hemorrhagic disorder.
- The common symptoms are spontaneous bleeding from mucous membranes (e.g., epistaxis), excessive bleeding from wounds or menorrhagia. In severe cases, manifestations may be similar to hemophilia A.

Acquired causes of vWF deficiency are listed on **Box 9.36**.

Laboratory Findings

- **Platelet count** is **normal.**
- **Bleeding time** is **prolonged** despite a normal platelet count because of defect in platelet function.

FIG. 9.49: Functions of von Willebrand factor (vWF).

Box 9.36: Acquired causes of vWF deficiency.

- Hematologic disorders
  - Lymphoproliferative disorders
- Myeloproliferative neoplasms including essential thrombocytosis (ET), systemic lupus erythematosus (SLE) and other autoimmune disorders, and cardiovascular disease
  - Congenital heart disease
  - Aortic stenosis
  - Left ventricular assist device or extra- corporeal membrane oxygenation
- Wilms tumor hypothyroidism
- Valproic acid and other medications

- **Tourniquet test (Hess test): Positive** due to defect in platelet adhesion.
- **APTT: Prolonged** because vWF stabilizes factor VIII by binding to it. A deficiency of vWF gives rise to a secondary decrease in factor VIII levels.
- **vWF assay:** Plasma level of active vWF is **decreased**.
- **Platelet function test:** Function of vWF is assessed by **ristocetin aggregation test**. Ristocetin induces multivalent vWF multimers to bind platelet glycoprotein Ib-IX and results in bridging of platelets to each other. The resultant clumping (agglutination) of platelets is measured by an aggregometer. The degree of ristocetin-dependent platelet agglutination is a measure of vWF activity. Defective ristocetin induced platelet aggregation is diagnostic of vWF.

Management

Management of bleeding

- Mild bleeding: Managed with desmopressin.
- Severe bleeding: Controlled by intravenous cryoprecipitate or plasma-derived concentrates containing vWF and factor VIII. Recombinant activated factor VII (rFVIIa,) has also been successfully used in vWD patients with severe hemorrhage refractory to vWF replacement therapy.

Vitamin K deficiency

- Clinically, it manifests as ecchymoses, bleeding from injection sites, bruises, gum bleeding, hematemesis, melaena, or hematuria.
- Both the PT and activated partial thromboplastin time are prolonged.
- Administration of vitamin K in a dose of 5–10 mg stops bleeding within 1–2 days.
- If blood loss is severe or response to vitamin K is inadequate, transfusion of fresh blood or fresh frozen plasma is indicated.

Fibrinolysis

Causes of excessive fibrinolysis have been shown in **Table 9.76**.

TABLE 9.76: Causes of excessive fibrinolysis.

- ➢ Obstetric: Abruptio placentae, amniotic fluid embolism
- ➢ Surgical: Gastrectomy, lung resection, nephrectomy, prostatectomy, cardiopulmonary bypass, splenectomy, pancreatectomy
- ➢ Medical:
  - Liver diseases (cirrhosis of liver)
  - Leukemias (acute leukemia, chronic granulocytic leukemia type IV)
  - Anaphylactic shock
  - Autoimmune diseases (systemic lupus erythematosus)

MICROANGIOPATHIC HEMOLYTIC STATES AND THROMBOCYTOPENIAS

Clinical Spectrum

- Hemolytic uremic syndrome
- Thrombotic thrombocytopenic purpura (TTP)
- Systemic sclerosis
- Malignant hypertension
- Preeclampsia–eclampsia
- Systemic lupus erythematosus
- Antiphospholipid antibody syndrome
- Renal transplant associated
- Drug induced
- Radiation therapy associated

Thrombotic Thrombocytopenic Purpura

Q. PA28.15 Describe the etiology, genetics, pathogenesis, pathology, presenting features and progression of thrombotic angiopathies.

Q. Discuss thrombotic thrombocytopenic purpura.

Thrombotic thrombocytopenic purpura (TTP) is a severe microangiopathic hemolytic anemia (MAHA), characterized by systemic platelet aggregation, organ ischemia, profound thrombocytopenia (with increased marrow megakaryocytes), fragmentation of erythrocytes, fever, and renal failure.

Etiology and Pathogenesis

- Normally endothelial cells and megakaryocytes secrete normal vWF multimers into the plasma. These multimers spontaneously develop into unusually large multimers which are most effective in mediating platelet adhesion.
- A plasma protease enzyme called ADAMTS13 ("vWF metalloprotease") regulates the activity of vWF by cleaving the hemostatically active unusually large multimers into normal multimers. Thus, ADAMTS13 regulates the size of vWF multimers and prevents platelet adhesion.
- TTP patients have an inherited or acquired deficiency of ADAMTS13. The deficiency leads to accumulation of unusually large multimers of vWF in plasma.
- These large multimers promote platelet adhesion or promote intravascular platelet aggregation and cause spontaneous activation of the coagulation cascade.
- This results in hyaline thrombi throughout the microcirculation, leading to tissue ischemia, and infarction that are characteristic of TTP.
- Secondary causes of acute TTP: These include pregnancy, oral contraceptives, SLE, infection, and drugs (ticlopidine and clopidogrel). They may or may not have associated antibodies to ADAMTS13.

Clinical Features

The classic five symptoms of TTP are (1) MAHA with schistocytosis (at least 3 cells per 100), (2) severe thrombocytopenia, (3) transient neurologic symptoms secondary to CNS ischemia, (4) fever, and (5) renal abnormalities including hematuria and/or proteinuria.

Laboratory Findings

- **Platelet count markedly reduced** often below 20,000/µL (thrombocytopenia).
- Peripheral blood smear shows fragmented red cells (called **schistocytes**) and numerous reticulocytes.
- PT, PTT, and fibrinogen concentration: Normal, because the coagulation system is not activated.
- Urine shows moderate proteinuria and both gross and microscopic hematuria.
- **Serum LDH: Raised** due to release from ischemic tissues.
- **ADAMTS13 activity: Reduced** below 5–10% of normal.

Diagnosis

Schistocytes and elevated serum LDH (out of proportion to the degree of hemolysis) suggest the diagnosis of TTP.

Treatment

- **Plasma exchange**
  - Daily plasma exchange (removing 40 mL/kg body weight of plasma and replacing it with equal volume of fresh frozen plasma) is the treatment of choice.
  - Provides ADAMTS13 and removes associated autoantibody in acute TTP.
  - Continued for at least 2 days after remission, which is defined as stabilization of clinical symptoms and return to normal of platelet count and LDH levels along with rising hemoglobin level.
  - Cryoprecipitate and fresh frozen plasma (FFP) also contain ADAMTS13 can be used.
- **Corticosteroids:** Pulsed intravenous methylprednisolone is given acutely and is generally added to plasma exchange to suppress formation of antibodies.
- **Rituximab:** It is a monoclonal antibody against CD20, suppresses antibody-producing cells. It is used in those patients who are refractory to plasma exchange and corticosteroids.
- **Splenectomy:** Performed in resistant cases which remove antibody-producing cells.
- **Platelet concentrates are contraindicated**.

Prognosis: Untreated cases have a mortality of up to 90% but with modern management it has been reduced to about 10%.

Hemolytic-Uremic Syndrome

Q. PE29.4 **Discuss the etiopathogenesis, clinical features and management of hemolytic uremic syndrome.**

Hemolytic-uremic syndrome is distinguished from TTP by the absence of fever and neurological symptoms, the prominence of acute renal failure (uremia), frequent affection of children, and different pathogenesis.

Etiology and Pathogenesis

- HUS develops following damage to the endothelium by toxins, drugs or radiation. One main cause of HUS in children and the elderly is infectious gastroenteritis caused by ***Escherichia coli*** **strain 0157:H7**.

- *E. coli* produces a Shiga-like toxin which is absorbed from the inflamed gastrointestinal mucosa.
- The toxin enters circulation and damages endothelial cells of microvasculature, mainly in the renal glomerular capillaries and initiates platelet activation and thrombi formation.
- *Pneumococcus* associated HUS-streptococcal neuraminidase exposes a novel antigen [Thomsen–Friedenreich (T) antigen] on RBCs/platelets/glomeruli
- **"Atypical" HUS**
  - Non-STEC, non-pneumococcal
  - Genetic and acquired factors leading to dysregulation of the alternative complement pathway
    - C3/C4
    - Factor H, factor I, factor B
    - MCP (CD46) expression on PBMCs
    - Factor H autoantibodies
    - Mutations
    - Direct exon sequencing of CFH, MCP, CFI, CFB, C3
    - Copy number variation across CFH-CFHR locus
- Red cells get trapped in the formed thrombi, undergo fragmentation resulting in schistocytes.
- Splenic trapping of the fragmented red cells causes extravascular hemolysis.

Differences between thrombotic thrombocytopenic purpura and hemolytic uremic syndrome are presented on **Table 9.77**.

TABLE 9.77: Differences between thrombotic thrombocytopenic purpura and hemolytic uremic syndrome.

Features	***Thrombotic thrombocytopenic purpura (TTP)***	***Hemolytic uremic syndrome (HUS)***
Age	Adults between 20 and 50 years	Children <5 years
Hemolytic anemia	With RBC fragmentation	With RBC fragmentation
Renal dysfunction	Mild to moderate	Acute renal failure
Thrombocytopenia	Present	Present
CNS symptoms	Severe	Mild
Fever	+	—

Clinical Features

- Age: HUS develops most commonly in children between 1 and 5 years of age a few days after an episode of bloody diarrhea. HUS can also develop in adults following certain drugs and radiation therapy that damage endothelial cells.
- Classical presentation: **Triad of microangiopathic hemolytic anemia, thrombocytopenia and renal failure** (oliguria). Hematuria and hypertension are also common. Despite thrombocytopenia, bleeding manifestations are rare.
- Complications: Fluid overload may result in pulmonary edema and hypertensive encephalopathy.

Investigations

- Hemoglobin levels: Decreased (anemia).
- Platelet count: Markedly reduced often below 20,000/μL (thrombocytopenia).
- Peripheral blood smear shows fragmented red cells (called schistocytes) and numerous reticulocytes.
- LDH: Elevated.
- Blood urea and creatinine: Elevated.
- Urine: May show proteinuria and red blood cells.
- PT and aPTT: Normal
- Stool: Culture for enterohemorrhagic *E. coli*-positive; shiga toxin-positive.

Treatment

- Supportive care: For the renal and hematological complications.
- Antibiotics: If shigellosis is suspected/detected.
- Experimental: Eculizumab, monoclonal antibody to C5.

Prognosis

With appropriate supportive care, they usually recover completely, but in more severe cases renal damage may result in death.

Disseminated Intravascular Coagulation

Q. PA21.4 Define and describe disseminated intravascular coagulation, its laboratory findings and diagnosis of disseminated intravascular coagulation (DIC: defibrination syndrome: consumption coagulopathy).

Disseminated intravascular coagulation is a widespread acute or chronic thrombohemorrhagic disorder in which a **combination of thrombosis and hemorrhage** develops as a secondary complication of a wide variety of disorders **(Table 9.78)**.

TABLE 9.78: Major disorders associated with disseminated intravascular coagulation.

1. Infections
- Gram-negative bacterial sepsis
- Meningococcemia and other bacteria
- Fungi, viruses, Rocky mountain spotted fever, malaria

2. Obstetric complications
- Retained dead fetus
- Septic abortion
- Abruptio placentae
- Amniotic fluid embolism
- Toxemia and preeclampsia

3. Neoplasms
- Carcinomas of pancreas, prostate, lung, and stomach
- Acute promyelocytic leukemia

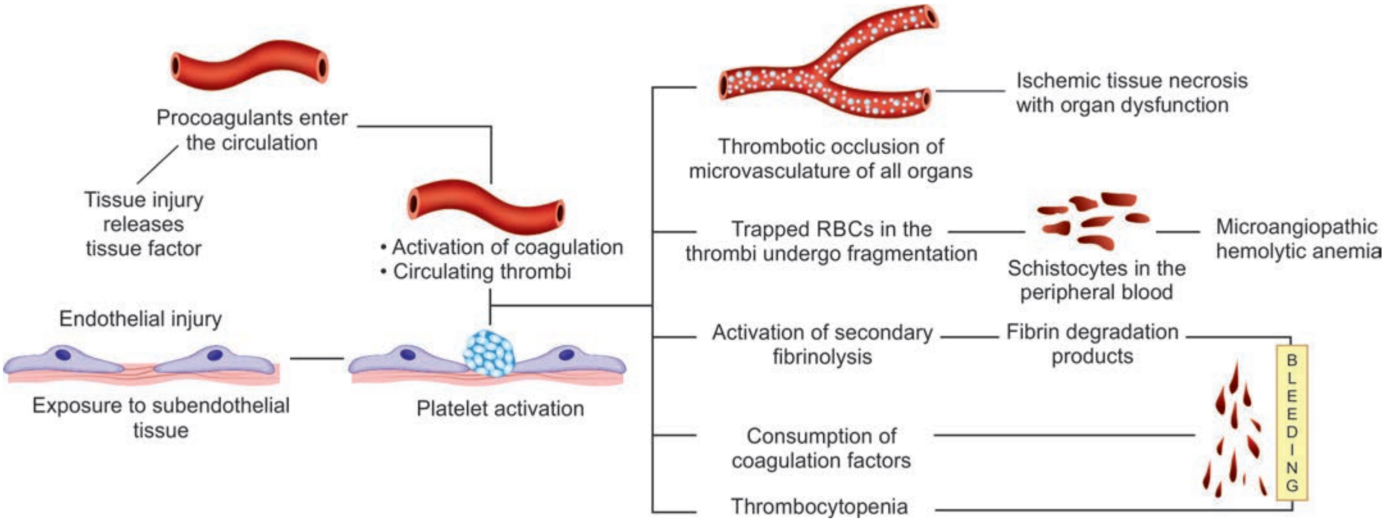
4. Massive tissue injury
- Traumatic
- Burns
- Fat embolism
- Surgery

5. Vascular disorders

Aortic aneurysm, giant hemangioma

6. Miscellaneous

Snakebite, liver disease, acute intravascular hemolysis, shock, heat stroke, hypersensitivity, vasculitis



Procoagulants enter the circulation
Tissue injury releases tissue factor
Endothelial injury
Exposure to subendothelial tissue
• Activation of coagulation
• Circulating thrombi
Platelet activation
Thrombotic occlusion of microvasculature of all organs
Ischemic tissue necrosis with organ dysfunction
Trapped RBCs in the thrombi undergo fragmentation
Schistocytes in the peripheral blood
Microangiopathic hemolytic anemia
Activation of secondary fibrinolysis
Fibrin degradation products
Consumption of coagulation factors
Thrombocytopenia
BLEEDING

FIG. 9.50: Pathogenesis of thrombosis, ischemic tissue necrosis, and bleeding in disseminated intravascular coagulation.

Pathogenesis (Fig. 9.50)

Clinical Features

- DIC is a serious, often fatal, important clinical condition which needs an immediate diagnosis and management. The symptoms of DIC depend on the nature, intensity and duration of the underlying disorder.
- Signs and symptoms are related to the tissue hypoxia and infarction caused by the microvascular thrombosis; or with bleeding diathesis due to the depletion of factors and the activation of fibrinolytic mechanisms; or both **(Table 9.79)**.
- Bleeding is the most common clinical feature in acute **DIC**. It may manifest as ecchymoses, petechiae, or bleeding from mucous membranes or at the sites of venipuncture.
- Microvascular thrombi cause ischemic necrosis of the organ with resultant dysfunction of the involved organ and occur most often with chronic underlying diseases. Organ dysfunction may manifest as hepatic, renal, cardiac, or respiratory failure or neurological disturbances. It may also result in gangrene of extremities and hemorrhagic necrosis of the skin.

TABLE 9.79: Effects and signs of disseminated intravascular coagulation.

Organ/site	*Due to thrombi in microvasculature*	*Due to hemorrhagic diathesis*
Central nervous system	Multifocal, delirium, coma	Intracerebral bleeding
Renal system	Cortical necrosis—oliguria, azotemia	Hematuria
Skin	Focal ischemic necrosis, gangrene	Petechiae, ecchymoses, bleeding at the sites of venipuncture
Gastrointestinal tract	Acute ulceration	Massive bleeding
Respiratory tract	Acute respiratory distress syndrome	
Mucous membranes		Epistaxis, gingival bleeding
Peripheral circulation	Fragmentation of trapped RBCs—microangiopathic hemolytic anemia	

- Waterhouse–Friderichsen syndrome: Occult thrombosis of adrenal vein thrombosis resulting in adrenal hemorrhage.
- Trousseau sign: Migratory venous thrombosis in cancers.
- Multiorgan dysfunction syndrome (MODS): Frequent consequence of DIC and is usually due to bleeding into organs or thrombotic alteration in various organs (hepatic, cardiac, central nervous, renal, and pulmonary systems).

Laboratory Findings (Investigations) in DIC (Table 9.80)

Q. Write a short note on investigations to diagnose DIC.

- ESR: Low
- Peripheral smear: Presence of schistocytes.
- **Screening assays**
  - **Platelet count:** Decreased because of utilization of platelets in microthrombi.
  - **PT:** Increased.
  - **APTT: Increased** because of consumption and inhibition of the function of clotting factors.
  - **Thrombin time (TT):** Increased because of decreased fibrinogen.
  - **Plasma fibrinogen:** Decreased.
  - Presence of schistocytes (fragmented RBCs) in the peripheral smear.
- **Confirmatory tests**
  - **FDP (fibrin degradation/split products):** Secondary fibrinolysis results in generation of FDPs, which can be measured by latex agglutination.
  - **D-dimer test:** D-dimer is formed during fibrinolysis as a result of degradation of cross-linked fibrin by plasmin. D-dimer levels are elevated and are specific for diagnosing DIC.
- Scoring system for DIC
- International Society of Thrombosis and Hemostasis DIC score has been shown in **Table 9.81**.

TABLE 9.80: Routine laboratory value abnormalities in DIC.

Test	*Abnormality*
Platelet count	Decreased
Prothrombin time	Prolonged
aPTT	Prolonged
Fibrin degradation products	Elevated
Protease inhibitors (e.g., protein C, AT, protein S)	Decreased

TABLE 9.81: International Society of Thrombosis and Hemostasis DIC score.

Test	*0 point*	*1 point*	*2 points*	*3 points*
INR	<1.25	1.25–1.5	>1.5	
Fibrinogen	>100 mg/dL	<100 mg/dL		
D-dimer	<400 ng/dL		400–4,000 ng/mL	>4,000 ng/mL
Platelets	>100,000	50,000–100,000	<50,000	

Interpretation of total score:
- ≥5 points: Overt DIC
- <5 points: Patients may still have non-overt DIC, could evolve into overt DIC

Q. Write a short note on management of DIC.

Management

- Control or elimination of the underlying cause (e.g., removal of a dead fetus, placenta, etc.).
- Correction of precipitating factors, e.g., acidosis, dehydration, sepsis and hypoxia.
- Management of hemorrhagic symptoms: It is necessary to maintain blood volume and tissue perfusion. Hemorrhagic symptoms are managed by transfusions of platelet concentrates, FFP, cryoprecipitate and red cell concentrates.
  - Dose:
    - Platelet concentrates: 1–2 units/10 kg.
    - Fresh frozen plasma: 15–20 mL/kg.
    - Cryoprecipitate: 1 unit/10 kg.
- Drugs to control coagulation such as heparin or antifibrinolytic drugs have been tried in DIC.
  - Heparin: Low doses of continuous infusion heparin (5–10 U/kg/h) are often used in patients with thrombotic manifestations. It should be given after the correction of bleeding. Major indications for heparin therapy are:
    - Purpura fulminans during the surgical resection of giant hemangiomas and during removal of a dead fetus.
    - Acute promyelocytic leukemia.
  - Antifibrinolytic drugs: For example, EACA, or tranexamic acid prevent fibrin degradation by plasmin may reduce bleeding episodes. However, they increase the risk of thrombosis and concomitant use of heparin is indicated.
  - **Antithrombin III, protein C concentrate, TFPI** have been tried

TRANSFUSION MEDICINE

Q. IM9.17 Describe the indications for blood transfusion and the appropriate use of blood components.

Q. IM15.12 Enumerate the indications for whole blood, component and platelet transfusion and describe the clinical features and management of a mismatched transfusion.

Transfusion medicine comprises blood and blood component/products transfusion. Blood cannot be synthesized artificially. So the source of blood is from a healthy human donor.

Whole Blood

- One unit of blood collected from a donor contains 450 mL ± 10% of blood and citrate anticoagulant that also contains phosphate and dextrose.
- Whole blood provides both oxygen-carrying capacity and volume expansion. However, it is rarely used because within a few hours or days, some coagulation factors (especially factors V and VIII) and platelets decrease in quantity or lose viability.

Red Cell Concentrates (Packed Red Cells)

- Packed red cells are obtained by centrifugation/sedimentation of the whole blood. All the plasma is removed and is replaced by about 100 mL of an optimal additive solution, such as SAG-M, which contains sodium chloride, adenine, glucose, and mannitol.
- In the packed red cell unit, the hematocrit is between 55 and 65%. Since, the volume is about 330 mL; there is less risk of volume overload.
- One unit of packed red blood cells raises hemoglobin concentration by 1 g/dL.

  General indications for RBC transfusion are mentioned in **Box 9.37**.

Box 9.37: General indications for RBC transfusion.

- Replace acute blood loss due to hemorrhage or during surgery to relieve clinical features caused by insufficient oxygen delivery
- Symptomatic anemia in an euvolemic patient
  - β-thalassemia major
  - Sickle cell anemia
  - Aplastic anemia
  - Severe anemia of any cause

Platelet Concentrate

- Platelet concentrate may be obtained from a single donor or pooled plasma. Platelets can also be obtained from a single donor by platelet apheresis SDP-single donor platelets.
- Platelets have ABO antigens on their surface but do not express Rh antigen. Hence, ABO matching is required. But it is advisable to transfuse Rh negative persons with platelets only from Rh negative persons. One platelet concentrate (PC) should increase the platelet count by 5,000–10,000/μL. Six units of pooled platelets or one apheresis unit should increase the platelet count by approximately 30,000/μL.
- Indications for platelet concentrate transfusion are mentioned in **Box 9.38**.

Box 9.38: Indications for platelet concentrate transfusion.

Bleeding due to:

- Severe thrombocytopenia (when platelet count is less than 20,000/mm^3).
  - Immune mediated: In patients with autoimmune thrombocytopenia, it should be reserved for patients with life-threatening bleeding.
  - Secondary to bone marrow failure
    - Chemotherapy induced
    - Due to leukemia
    - Dilutional
- Abnormal platelet function
- Disseminated intravascular coagulation (DIC)
- Surgical or invasive procedures in thrombocytopenic patients

Contraindication to platelet concentrate transfusion

- Thrombotic thrombocytopenic purpura (TTP)
- Heparin-induced thrombocytopenia (HIT).
- Relative contraindication: Idiopathic thrombocytopenic purpura (ITP) or post-transfusion purpura (PTP) because the survival of transfused platelets is very brief.

Granulocyte Concentrates

- Indications: Severe neutropenia with definite evidence of bacterial infection.
- It is not frequently employed, because it is preferable to administer the growth factors for myelopoiesis like G-CSF/GM-CSF. But it is indicated when granulocyte count is less than 500/mm^3 (agranulocytosis), and to combat infections (in neonatal sepsis and chronic granulomatous disease).

Fresh Frozen Plasma

- The volume is about 200 mL and contains all the coagulation factors (including vWF). Present in fresh plasma. The volume transfused depends on the clinical situation and patient size, and should be guided by laboratory assays of coagulation function. The general guide is 10–15 mL/kg per dose.
- ABO matching is essential before infusion of FFP. Rh compatibility is not required

Cryoprecipitate

- Contains concentrated precipitate of factor VIII, XIII, vWF, and fibrinogen.
- Does not require crossmatching before transfusion.
- **Indications:**
  - DIC and other conditions where the fibrinogen level is very low (hypofibrinogenemia).
  - It was used for hemophilia, factor XIII deficiency, and von Willebrand disease. However, it is no longer used for these disorders because of the greater risk of virus transmission compared with virus-inactivated coagulation factor concentrates.
- Various coagulations factors and their amount in one unit of cryoprecipitate are mentioned in **Table 9.82**.

Indications: For replacement of coagulation factors in acquired coagulation factor deficiencies

- Patients on anticoagulant drug therapy (Coumarin)
- Antithrombin deficiency
- Coagulopathy of liver diseases
- Vitamin K deficiency
- Microangiopathic hemolytic anemia including TTP, hemolytic uremic syndrome, and HELLP syndrome
- DIC

TABLE 9.82: Various coagulations factors and their amount in one unit of cryoprecipitate.

Coagulation factor	*Quantity per unit*
Fibrinogen	150–250 mg
Factor VIII	80–150 units
Von Willebrand factor	100–150 units
Factor XIII	50–75 units

Factor VIII and IX Concentrates

- These are freeze-dried preparations of specific coagulation factors prepared from large pools of plasma from many donors.
- **Indications:** For patients with hemophilia and von Willebrand's disease, where recombinant coagulation factor concentrates are unavailable.

Saline-washed Red Blood Cells

Saline washing of red cells is an effective means of removing leukocytes and plasma (up to 99%). This product is largely restricted to patients with antibodies to IgA or IgE, and those requiring red cells with minimal plasma as in **thalassemia and paroxysmal nocturnal hemoglobinuria.**

Frozen Red Blood Cells

Red blood cells can be freezed and stored up to 3 years by addition of glycerol as an endocellular cryoprotective agent. This procedure is used for storage of rare blood groups. Frozen red cells may be indicated for patients with history of severe allergic reactions to plasma or leukocyte factors, e.g., patients sensitized to IgA.

Irradiated Blood Products

Cellular blood products (red cells, platelets, granulocytes) can be irradiated to a dose of 1,500 rads before transfusion in order to minimize the risk of transfusion-**acquired graft-versus-host disease** in immunocompromised individuals.

Immunoglobulins

Rh Immune Globulin

Indications

- Known or suspected inoculation of Rh– mother with unknown or Rh+ fetal red cells, e.g., abortion, threatened abortion, ectopic pregnancy, amniocentesis, abdominal trauma in 2nd or 3rd trimester, postpartum if new born is Rh+.
- Following transfusion of Rh+ cellular blood products (e.g., platelets) to an Rh– female of child bearing age or younger.
- Acute ITP resistant to steroids.

Safe Transfusion Procedures

Q. IM9.18 Describe the precautions required necessary when performing a blood transfusion.

Pretransfusion Testing

Before transfusion of any blood or its components, it is necessary to know whether they are compatible with the recipient's blood.

- **Donor blood:** The tests routinely carried out on donor's blood include ABO and Rh grouping, tests for HBsAg, anti-HCV, anti-HIV-1 and HIV-2 and serum alanine aminotransferase (ALT), malaria, and syphilis.
- **Recipient blood:** The recipient's ABO and Rh grouping is also carried out.

Compatibility Testing

These are a set of procedures which include: Review of patient's past blood bank history and records (if done earlier), ABO and Rh typing of the recipient and donor, antibody screening test of recipient's and donor's serum followed by crossmatching. It is sometimes referred to as crossmatching. However, crossmatch is only a part of the compatibility test.

Crossmatching: Crossmatching is very important before any blood transfusion. Crossmatching should be carried out to ensure that there are no antibodies in the patient's serum that will react with the donor's cells when transfused. Full crossmatching requires about 45 minutes if no red cell antibodies are present, but may need hours if a patient has multiple antibodies.

- **Importance of cross-matching:**
  - It is the final check of ABO compatibility between donor and recipient.
  - Detects the presence of any clinically significant, unexpected antibodies in the recipient's serum that may react with the donor's cells, thereby preventing any transfusion reaction.
- **Types:** Crossmatching procedure may involve **major and minor** crossmatching. Major crossmatching consists of mixing donor's red cells with recipient's (patient's) serum; whereas minor crossmatching consists of mixing patient's red cells with donor's serum.

Bedside Procedures for Safe Transfusion

- An error of patients receiving the wrong blood is an avoidable cause of mortality and morbidity in transfusion medicine.
- Most incompatible transfusions are due to failure to adhere to standard procedures for taking correctly labeled blood samples and ensuring that the correct pack of blood component is transfused into the intended recipient.
- It is always necessary to monitor the recipient during and after transfusion so that any complications can be dealt with accordingly.

Complications of Blood Transfusion

Q. PA22.6 Describe transfusion reactions and enumerate the steps in the investigation of a transfusion reaction.

Complications of blood transfusion have been shown in **Table 9.83.**

TABLE 9.83: Complications of blood transfusion.

Immunological complications	*Nonimmunological complications*
➢ **Immediate reactions** – Acute hemolytic transfusion reactions – Febrile nonhemolytic reaction – Allergic reaction—urticaria – Anaphylactic reactions – Transfusion-related acute lung injury (TRALI) ➢ **Delayed reactions** – Alloimmunization – Delayed hemolytic transfusion reactions (mostly asymptomatic) – Transfusion associated graft-versus-host disease – Post-transfusion purpura	➢ **Immediate** – Circulatory overload – Air embolism ➢ **Late** – Iron overload: Transfusion hemosiderosis – Thrombophlebitis – Infections: ◆ Hepatitis (HBV, HCV, and HDV) ◆ HIV (AIDS) ◆ Malaria ◆ Cytomegalovirus ◆ Syphilis

Immunological Complications/Reactions

Acute Hemolytic Transfusion Reaction

- Most serious complication of blood transfusion.
- Cause: Occurs due to transfusion of incompatible donor red cells resulting in destruction of donor cells. Usually due to ABO incompatibility.

Clinical features

- The initial symptoms may **occur within a few minutes after starting the transfusion**. Patients typically develop fever with chills, pain in the lumbar region, dyspnea, pruritus, burning sensation at the site of transfusion and centrally along the vein, and chest pain.
- In an unconscious patient, more severe features like hypotension, shock, intravascular hemolysis which results in hemoglobinuria and oliguria with acute renal failure and excessive bleeding due to DIC may develop.

Diagnosis

In the majority of cases, this results from clerical errors like wrong labeling of the crossmatch sample, improper checking or transfusion to the wrong recipient, confirmed by finding evidence of hemolysis (e.g., hemoglobinuria), and incompatibility between donor and recipient.

Management

- Stop the transfusion immediately if there is any suspicion of a serious transfusion reaction.
- Change the blood transfusion set and maintain the venous access using normal saline.
- Perform physical examination such as blood pressure, urine output and evidence of bleeding. Emergency treatment may be needed to maintain the blood pressure and renal function.
- Withdraw new blood samples from the opposite arm of the patient and send it to the blood transfusion laboratory along with the donor units to exclude a hemolytic transfusion reaction.
- Centrifuge one more blood sample from the recipient of transfusion and look for any free hemoglobin in the supernatant.
- Perform coagulation screening tests including partial thromboplastin time, platelet count, fibrinogen levels and fibrin-degradation products to exclude DIC. Laboratory evaluation for hemolysis includes the measurement of serum haptoglobin, lactate dehydrogenase (LDH) and indirect bilirubin levels.
- If hypotension develops, administer intravenous fluids and if required, vasopressors.
- Administer diuretic furosemide to maintain urine output.

Febrile Nonhemolytic Transfusion Reactions (FNHTR)

- Common complication of blood transfusion.
- Cause: Usually develop due to presence of leukocyte antibodies in patients who have previously been transfused or pregnant. Can also occur due to release of cytokines from donor leukocytes in platelet concentrates.
- Time of occurrence: Usually occurs toward the end of infusion or within hours of completing the transfusion.
- Typical signs: Flushing and tachycardia, fever (>38°C), chills, and rigors.

Allergic Reactions—Urticaria

- Common but rarely severe.
- Cause: Urticarial reactions mostly result from plasma-protein incompatibility due to the presence of antibodies in the recipient's blood to infused plasma proteins or infusion of allergens that react with IgE antibodies in the patient.

Treatment: Stop or slow the transfusion and administer 10 mg of chlorpheniramine intravenously.

Anaphylactic Reactions

- These are severe reactions which develop after transfusion of only a few milliliters of the blood component.
- Severe reactions are seen in patients who have antibodies against IgA and are often deficient in IgA. The antibodies react with IgA present in the donor blood.
- Symptoms and signs: Difficulty in breathing, coughing, nausea and vomiting, hypotension, bronchospasm, loss of consciousness, respiratory arrest, and shock.
- Treatment: Stop transfusion and maintain vascular access. Immediately administer 0.5 mg epinephrine (adrenaline) IM, and 10 mg chlorpheniramine, IV glucocorticoids, and endotracheal intubation may be required in severe cases.

Transfusion Related Acute Lung Injury (TRALI)

- Cause: TRALI usually develops from the transfusion of donor plasma that contains high-titer anti-HLA antibodies that bind recipient leukocytes. This produces aggregation of leukocytes in the pulmonary vasculature and releases mediators that increase capillary permeability. Such antibodies are most frequently found in females after pregnancy and are not found in plasma of males unless they have been transfused.
- Patient develops an acute respiratory distress, either during or within 6 hours of transfusing the patient. It is characterized by fever, cough, shortness of breath, and typical bilateral interstitial infiltrates on chest X-ray. The reaction occurs during or soon after transfusion and may be life-threatening.

Treatment: Supportive and patients usually recover without any sequelae.

Delayed Hemolytic Transfusion Reactions (DHTRs)

- These are not completely preventable.
- Cause:
    - May occur in patients previously sensitized to RBC alloantigens (such as Rh, Kidd, Kell, Duffy) by previous transfusions or pregnancies.
    - The antibody level is too low to be detected by pretransfusion compatibility testing.
    - When the patient is transfused with antigen-positive blood, there is early production of alloantibody (usually by IgG antibodies) that binds donor RBCs, resulting in destruction of the transfused donor cells.

- Occurs 3–21 days after transfusion with the incompatible blood.
- Direct Coombs' test (DAT): Positive, if carried out during hemolysis. Later, patients may show only positive indirect Coombs' test.

Treatment: Usually no specific therapy is required.

Transfusion-associated Graft-versus-host Disease (TA-GVHD)

- Rare but potentially fatal complication.
- Develops 8–10 days, and death occurs at 3–4 weeks after transfusion.
- **Mechanism:** Donor blood products contain mature T lymphocytes that recognize host HLA antigens as foreign and mount an immune response and attack upon recipient's tissues. It is observed more commonly in immunocompromised recipients.
- Clinical features include fever, generalized characteristic skin rash, jaundice (with abnormalities of liver function), diarrhea, and features of pancytopenia (due to marrow failure).
- **Prevention:** TA-GVHD can be prevented by transfusing the irradiated blood/components in patients at risk.
- It is highly resistant to treatment with immunosuppressive therapies, including glucocorticoids, cyclosporine, antithymocyte globulin, etc.

Post-transfusion Purpura

- It is an immune-mediated thrombocytopenia that usually occurs predominantly in parous women.
- Antibodies against human platelet antigens (HPAs) are found in the patient's serum.
- It occurs 7–10 days after platelet transfusion.
- Thrombocytopenia is usually severe and may cause bleeding.
- Platelet transfusions are usually ineffective and can worsen the thrombocytopenia and hence should be avoided.

Treatment: Treatment with high-dose (0.4 g/kg/day for 5 days). Intravenous immunoglobulin may neutralize the effector antibodies, or plasmapheresis can be used to remove the antibodies.

Alloimmunization

- Alloimmunization usually does not cause clinical problems with the first transfusion but these may occur with subsequent transfusions. Delayed consequences of alloimmunization, include HDN (hemolytic disease of the newborn) and rejection of tissue transplants.
- Types:
  - Alloantibodies to RBC antigens
    - Detected during pretransfusion testing and may delay finding antigen-negative crossmatch-compatible products for transfusion.
    - Alloimmunization may develop during pregnancy to fetal RBC antigens (i.e., D, c, E, Kell, or Duffy) inherited from the father and not shared by the mother.
  - Alloimmunization to antigens on leukocytes and platelets: It can lead to refractoriness to platelet transfusions.

Nonimmune Complications/Reactions

Q. Write a short note on infections transmitted by blood transfusion.

- **Circulatory overload:** Significant in the elderly, pregnant women, those with reduced cardiac function (e.g., cardiac failure) or renal failure resulting in acute pulmonary edema.
- **Air embolism:** It used to develop in olden days when transfusion was given from the glass bottle.
- **Iron overload (transfusion siderosis)**
  - This is seen in patients who receive multiple transfusions over a period of few years (e.g., thalassemia). The excess iron gets deposited in reticuloendothelial cells of the spleen, bone marrow, liver, heart and endocrine glands.
  - Iron overload can be prevented or reduced by giving iron chelating agents
- **Thrombophlebitis:** Inflammation of vein may develop in patients with indwelling catheters.
- **Infectious complications:** Transfusion of infected blood may transmit a few diseases like AIDS, hepatitis (HBV, HCV and HDV), HTLV-I and II, malaria, and cytomegalovirus infection. This is prevented by screening the donors for these common and ominous infections.

Massive transfusion is defined as transfusion of more than 10 units of red cells or replacement of 1 blood volume in 24 hours. The use of large quantities of stored blood in massive transfusions may lead to a number of complications. Among these are dilutional coagulopathy, circulatory overload, hyperkalemia, hypoglycemia, hypothermia, and rarely, citrate-induced hypocalcemia.

Blood Groups and Diseases

- The first established disease relationship was between carcinoma of the stomach and group A.
- Duodenal ulcer is 1.4 times more common in group O patients.
- It is also reported that group A individuals have greater levels of factor VIII than group O, and hence greater complications of bleeding are seen in group O than A.
- A relationship between the Duffy (Fy) blood group and malaria is well established. It is seen in West Africa where the frequency of Fy a-b- is about 90%; these individuals are resistant to *Plasmodium vivax*. Experimentally, it has been shown that antigens Fya and Fyb act as receptors for the parasite to enter the cell.
- The Kell (K) group is associated with chronic granulomatous diseases and Rh null is implicated in autoimmune hemolytic anemia.

BONE MARROW EXAMINATION

Q. IM9.11, PA17.2 Describe the indications and interpret the results of a bone marrow aspirations and biopsy.

Bone marrow examination is essentially done to confirm or rule out a hematologic disorder. It also helps in evaluation of non hematological disorders (e.g., metastasis).

Bone marrow may be obtained by:

- **Aspiration:** Bone marrow aspiration is a simple, easy, and safe procedure
- **Trephine biopsy** is indicated in conditions where the aspiration either fails to yield marrow or to confirm some of the diseases (where biopsy findings are diagnostic).

Sites for bone marrow aspiration are listed in **Box 9.39**. Indications for bone marrow aspiration **(Table 9.84)**.

Contraindications for bone marrow aspiration: Hemophilia and congenital hemorrhagic disorders. Complications of bone marrow aspiration and biopsy are listed in **Box 9.40**.

Box 9.39: Sites for bone marrow aspiration.

Usual sites for bone marrow aspiration are:

- Sternum
- Posterior superior iliac spine
- Iliac crest
- Anterior superior iliac spine
- Spinous process of lumbar vertebra

In **infants**, upper end of the tibia is the ideal site for marrow aspirate

Box 9.40: Complications of bone marrow aspiration and biopsy.

- Local infection
- Hemorrhage
- Cardiac tamponade or mediastinitis

TABLE 9.84: Indications for bone marrow aspiration.

- ***Diagnostic***
  - **Primary hematolymphoid disorders**
    - **Red cell disorders:** Nutritional anemia (e.g., megaloblastic anemia), pure red cell aplasia
    - **White cell disorders:** Subleukemic/aleukemic leukemia, diagnosis and classification of acute leukemias
    - **Megakaryocytic disorders:** ITP and other thrombocytopenias
    - **Myeloproliferative neoplasms:** Polycythemia vera, chronic myeloid leukemia, idiopathic thrombocythemia
    - **Myelodysplastic syndromes**
    - **Plasma cell neoplasms:** Multiple myeloma, Waldenström macroglobulinemia
  - **Systemic diseases:** Storage disorders (e.g., Gaucher's, Niemann–Pick's disease)
  - **Staging of lymphoid malignancies and solid tumors:** Lymphoma, metastatic deposits (e.g., carcinoma prostate, breast, lung, kidney)
  - **Detection of infection and/or source of PUO**
    - **Parasitic disorders:** Kala-azar
    - **Fungal disorders:** Histoplasma
    - **Mycobacterial infection**
  - **Iron store**
  - **Miscellaneous disorders:** Pancytopenia or unexplained cytopenias
- ***Post-treatment follow-up:*** To know the response to therapy and follow up in cases of leukemia, aplastic anemia, and agranulocytosis
- ***Therapeutic:*** Bone marrow transplant

SPLEEN

The spleen is a hematopoietic organ capable of supporting elements of the erythroid, myeloid, megakaryocytic, lymphoid, and monocyte-macrophage (i.e., reticuloendothelial).

Splenomegaly

Q. PA19.6 Enumerate and differentiate the causes of splenomegaly.

Definition: The "gold-standard" definition of splenomegaly is splenic weight: The normal adult spleen weighs about 50–250 g. The weight can only be established at splenectomy or postmortem examination. The clinical finding of a palpable spleen was considered as splenic enlargement, but up to 16% of palpable spleens have been found to be of normal size on radiological assessment.

On ultrasound examination, “craniocaudal length” is commonly used to measure splenic size. This correlates with splenic volume. However, the upper limit of normal size varies from 11 to 14 cm.

Mechanisms of Splenomegaly

Many of the mechanisms represent exaggerated forms of normal function of spleen **(Table 9.85 and Box 9.41)**.

TABLE 9.85: Mechanisms of splenomegaly.

Mechanism	***Examples***
Immune response work hypertrophy	Subacute bacterial endocarditis, infectious mononucleosis
RBC destruction work hypertrophy	Hereditary spherocytosis, thalassemia major
Congestive	Splenic vein thrombosis, portal hypertension
Myeloproliferative	Chronic myeloid metaplasia
Infiltrative	Sarcoidosis, some neoplasms
Neoplastic	Chronic lymphocytic leukemia, lymphomas
Miscellaneous	Trauma, cysts

Box 9.41: Functions of spleen.

- Clearance of microorganisms and particulate antigens from the blood
- Synthesis of immunoglobulin and properdin factors
- Destruction of senescent or abnormal RBCs
- Embryonic hematopoiesis, which can be reactivated as extramedullary
- hematopoiesis in certain diseases (e.g., primary myelofibrosis)

Diseases Associated with Splenomegaly

Diseases associated with splenomegaly have been shown in **Table 9.86**.

TABLE 9.86: Diseases associated with splenomegaly.

Infection
- **Acute:** Infectious mononucleosis, viral hepatitis, septicemia, typhoid, cytomegalovirus, toxoplasmosis
- **Subacute/chronic:** Miliary tuberculosis, subacute bacterial endocarditis, brucellosis, syphilis, HIV
- **Tropical/parasitic:** Malaria, leishmaniasis/kala-azar, schistosomiasis

Hematological disorders
- **Myeloproliferative disorders:** Myelofibrosis, chronic myeloid leukemia (CML), polycythemia vera, essential thrombocytosis
- **Lymphoma:** NHL, HL
- **Leukemia:** Acute leukemia, chronic lymphocytic leukemia (CLL), hairy cell leukemia, prolymphocytic leukemia
- **RBC disorders**
  - **Congenital:** Hereditary spherocytosis, thalassemia, HbSC disease
  - **Others:** Autoimmune hemolysis, megaloblastic anemia
- **Congestive:** Cirrhosis, splenic/portal/hepatic vein thrombosis or obstruction, congestive cardiac failure

Inflammatory diseases
- **Collagen diseases:** Systemic lupus erythematosus, rheumatoid arthritis (Felty’s)
- **Granulomatous:** Sarcoidosis
- **Neoplastic:** Hemangioma, metastasis (lung/breast carcinoma, melanoma)
- **Infiltrative:** Gaucher’s disease, amyloidosis
- **Miscellaneous:** Cysts

Causes of Asymptomatic Splenomegaly

Causes of asymptomatic splenomegaly have been shown in **Table 9.87**.

TABLE 9.87: Causes of asymptomatic splenomegaly.

- Liver disease with portal hypertension
- Splenic vein thrombosis
- Agnogenic myeloid metaplasia
- Gaucher’s disease
- Splenic cysts
- Sarcoidosis
- Amyloidosis
- Mild hereditary spherocytosis
- Early stages of polycythemia vera

Causes of Massively Enlarged Spleen (Table 9.88 and Fig. 9.51)

Causes of massively enlarged spleen have been shown in **Table 9.88**.

TABLE 9.88: Causes of massively enlarged spleen.

- Chronic myeloid leukemia
- Myelofibrosis (primary or secondary to polycythemia vera or essential thrombocytosis)
- Hyper-reactive malarial splenomegaly syndrome (tropical splenomegaly syndrome)
- Gaucher's disease
- Lymphoma (mantle cell lymphoma, marginal B cell lymphoma), hairy cell leukemia
- Kala-azar (visceral leishmaniasis)
- Beta thalassemia major
- AIDS with *Mycobacterium avium* complex
- Splenic cysts

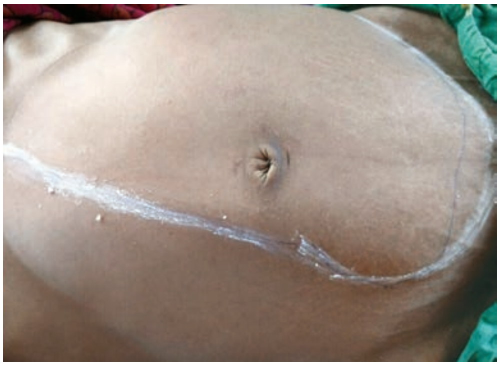


FIG. 9.51: Massively enlarged spleen.

Q. Write a short essay/note on causes of massive splenomegaly.

A spleen is considered as massively enlarged when its lower pole is within the pelvis or which has crossed the midline into the right lower or right upper abdominal quadrants.

Indications for Splenectomy

Indications for splenectomy have been shown in **Box 9.42**.

Hypersplenism

Splenomegaly is often accompanied by hypersplenism. This is a complication of splenomegaly and not a diagnosis. The specific cause of the splenomegaly must be determined. Classical features of hypersplenism are listed in **Box 9.43**.

Causes of Splenic Rupture

Causes of splenic rupture have been shown in **Box 9.44**.

DISORDERS OF HEME SYNTHESIS: THE PORPHYRIAS

- The porphyrias are caused by deficiencies of enzymes involved in heme synthesis, which lead to blockade of the porphyrin pathway and subsequent accumulation of porphyrins and their precursors.
- **Cause:** Most of the porphyria is due to partial enzyme deficiencies. These enzyme deficiencies may be inherited as autosomal dominant, autosomal recessive, or X-linked traits, with the exception of porphyria cutanea tarda (PCT), which usually is sporadic.

Classification

Due to deficiency of an enzyme involved in the synthesis of heme, there is build-up of porphyrins and metabolites in various tissues. It is classified depending on the site of overproduction and accumulation of porphyrin but overlapping features are common. It may be classified as follows:

- Depending on the major primary site of excess production and accumulation of their respective porphyrin precursors or porphyrins: (1) **Hepatic** (in the liver) or (2) **erythropoietic** (in the red cell).
- Based on the clinical manifestations **as acute or cutaneous**.

Box 9.42: Indications for splenectomy.

- **Hematological:** Isolated thrombocytopenia, immune thrombocytopenic purpura (ITP), hemolytic anemia, autoimmune hemolytic anemia, warm type (AIHA), hereditary spherocytosis, thalassemia major or intermedia, neutropenia, primary myelofibrosis
- Hairy cell leukemia, splenic marginal zone lymphoma, chronic lymphocytic leukemia
- Painfully enlarged spleen
- Traumatic or atraumatic splenic rupture, blunt abdominal trauma with splenic contusion or rupture
- Splenic artery aneurysm
- Hypersplenism
- Primary treatment of an isolated splenic vascular or parenchymal lesion
- Splenic abscess, acute splenic torsion with infarction due (e.g., "wandering spleen syndrome") splenic infarction
- Splenic vein thrombosis with bleeding esophageal varices
- Splenorenal shunting for portal hypertension

Box 9.43: Classical features of hypersplenism.

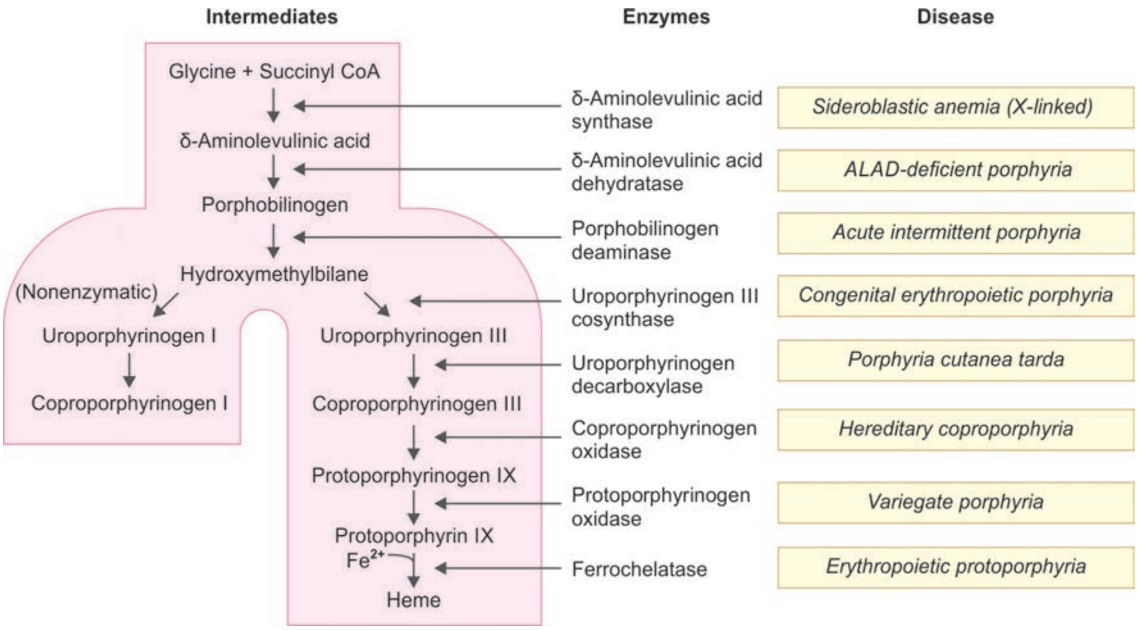
- Splenomegaly
- Any combination of anemia, leukopenia, and/or thrombocytopenia
- Compensatory bone marrow hyperplasia
- Improvement after splenectomy

Box 9.44: Causes of splenic rupture.

Traumatic splenic rupture: Blunt abdominal trauma

Atraumatic splenic rupture:

- Neoplasm, e.g., leukemia, lymphoma
- Infection, e.g., infectious mononucleosis, CMV, HIV, endocarditis, malaria
- Inflammatory disease/noninfectious disorders, e.g., acute and chronic pancreatitis, primary amyloidosis
- Drug and treatment related, e.g., anticoagulation, G-CSF, thrombolytic therapy, dialysis
- Mechanical causes, e.g., pregnancy-related, congestive splenomegaly
- Idiopathic (normal spleen)



Intermediates
Enzymes

(Nonenzymatic)
Uroporphyrinogen I
Coproporphyrinogen I
Uroporphyrinogen III
Coproporphyrinogen III
Protoporphyrinogen IX
Protoporphyrin IX
Fe2+
Heme
δ-Aminolevulinic acid synthase
δ-Aminolevulinic acid dehydratase
Porphobilinogen deaminase
Uroporphyrinogen III cosynthase
Uroporphyrinogen decarboxylase
Coproporphyrinogen oxidase
Protoporphyrinogen oxidase
Ferrochelatase
Sideroblastic anemia (X-linked)
ALAD-deficient porphyria
Acute intermittent porphyria
Congenital erythropoietic porphyria
Porphyria cutanea tarda
Hereditary coproporphyria
Variegate porphyria
Erythropoietic protoporphyria

FIG. 9.52: Intermediates accumulated and deficient enzymes in various porphyrias.

Structure of porphyrins: It consists of four pyrrole rings. Two molecules of δALA condense to form a pyrrole ring. Depending on the structure of the side chain, porphyrins can be divided into uroporphyrins, coproporphyrins, or protoporphyrins.

Intermediates accumulated and deficient enzymes in various porphyrias are depicted in **Figure 9.52**.

The three most common porphyrias are PCT, acute intermittent porphyria (AIP), and erythropoietic protoporphyria (EPP).

Clinical Features

Two broad patterns of symptoms occur in the various types of porphyria **(Table 9.89)**: (1) Cutaneous photosensitivity, and (2) acute neurovisceral syndrome.

Cutaneous Photosensitivity

- These are due to excess production and accumulation of porphyrins in the skin and occur predominantly on areas of the skin that are exposed to sunlight.

TABLE 9.89: Major porphyrias and their laboratory findings.

Porphyria	***Deficient enzyme***	***Principal symptoms***	***Elevated porphyrins and precursors***		
			RBCs	***Urine***	***Stool***
Hepatic porphyrias					
5-ALA dehydratase-deficient porphyria (ADP)	ALA-dehydratase	Neurovisceral	Zn-Protoporphyrin	ALA, Coproporphyrin III	
Acute intermittent porphyria (AIP)	HMB (hydroxymethylbilane)-synthase	Neurovisceral		ALA, PBG, Uroporphyrin	
Porphyria cutanea tarda (PCT)	Urodecarboxylase	Cutaneous photosensitivity		Uroporphyrin, 7-carboxylate porphyrin	Isocoproporphyrin
Hereditary coproporphyria (HCP)	Copro-oxidase	Neurovisceral and cutaneous photosensitivity		ALA, PBG, Coproporphyrin III	Coproporphyrin III
Variegate porphyria (VP)	Proto-oxidase	Neurovisceral and cutaneous photosensitivity			Coproporphyrin III Protoporphyrin
Erythropoietic porphyrias					
Congenital erythropoietic porphyria (CEP)	Urosynthase	Cutaneous photosensitivity	Uroporphyrin I Coproporphyrin I	Uroporphyrin Ib Coproporphyrin Ib	Coproporphyrin I
Erythropoietic protoporphyria (EPP)	Ferrochelatase	Cutaneous photosensitivity			
X-linked protoporphyria (XLP)	ALA-synthase 2	Cutaneous photosensitivity	Protoporphyrin	—	Protoporphyrin

- Two main patterns of skin damage are seen in the porphyrias:
  1. Due to accumulation of water soluble uro- and coproporphyrins leads to blistering.
  2. Due to accumulation of the lipophilic protoporphyrins leads to burning sensations in the exposed skin.
- They produce pain, erythema, bullae, skin erosions, hirsutism and hyperpigmentation. Skin also becomes sensitive to damage from minimal trauma.

Acute Neurovisceral Syndrome

This presents with acute abdominal pain and features of autonomic dysfunction (e.g., tachycardia, hypertension, and constipation). Acute motor polyneuropathy may cause quadriparesis mimicking GB syndrome. Neuropsychiatric manifestations include insomnia, anxiety, restlessness, agitation, hallucinations, hysteria, disorientation, delirium, apathy, depression, and phobias.

Triggering factors: Porphyria can relapse and remit or follow a prolonged and unremitting course. Sometimes, it may be triggered by alcohol, fasting, or drugs such as anticonvulsants, sulphonamides, estrogen, and progesterone.

Diagnosis

- Diagnosis and classification depends on the pattern of the porphyrins and porphyrin precursors found in blood, urine, and stool **(Table 9.89)**. Urine gets colored on exposure to sunlight **(Fig. 9.53)**.
- Measurement of the deficient enzymes.
- Genetic testing

Prevention

- Avoid sunlight (sun exposure) and skin trauma.
- Use of barrier sun creams containing zinc or titanium oxide and protective clothing.
- Oral β-carotene prevents formation of free radicals and provides effective protection against solar sensitivity.
- **Afamelanotide**, a synthetic analogue of alpha-melanocyte-stimulating hormone (α-MSH) is useful in EPP.

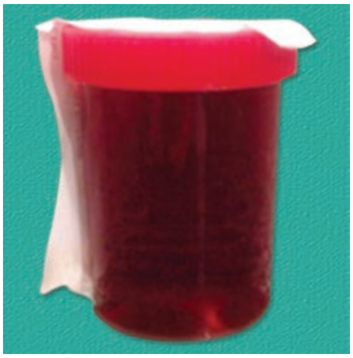

FIG. 9.53: High colored urine on exposure to sun-light in porphyria.

Management

Neurovisceral

Acute: The management of acute episodes is largely supportive.

- Analgesics to be given and avoid drugs that may aggravate an attack.
- **Specific management:**
  - **Intravenous glucose** inhibits ALA synthase activity leading to reduced ALA synthesis. In some cases, it can terminate acute attacks.
  - **Intravenous heme** (in various forms such as human hematin or heme arginate) infusion reduces ALA and PBG excretion by having a negative effect on ALA synthase N activity. It relieves pain and accelerates recovery and decreases the duration of an attack and is useful in a severe attack.
  - Maintain calorie and fluid intake.
  - Cyclical acute attacks in females may respond to suppression of the menstrual cycle using gonadotropin-releasing hormone analogs.

Cutaneous Photosensitivity Episodes

Acute attack

- Treated symptomatically.
- Venesection (reduces urinary porphyria) can be used for PCT in both acute and remission phases. A prolonged course of low-dose chloroquine is effective as it helps in excretion by forming a water-soluble complex with uroporphyrins.
- Liver transplantation may be useful for severe cases.

Pseudoporphyria

- In certain settings, the patient develops blistering and skin fragility identical to PCT with the histological features but with normal urine and serum porphyrins. Hypertrichosis, dyspigmentation, and cutaneous sclerosis do not occur. This condition is called pseudoporphyria.
- Most commonly due to medications especially NSAIDs, usually naproxen other NSAIDs and tetracycline can cause a similar picture.
- Some patients on hemodialysis develop a similar PCT-like picture.

CHAPTER

10

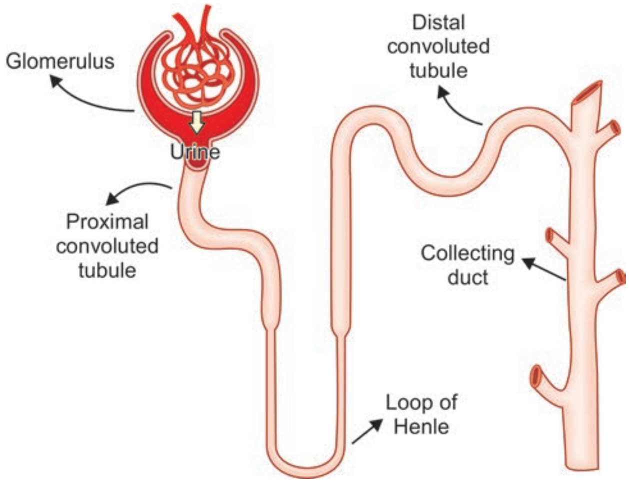
Kidney

FUNCTIONAL ANATOMY OF KIDNEY

Q. Describe the nephron with the help of a diagram. What are the functions of the kidney?

Unit of Kidney

The nephron is the structural and functional unit of the kidney. It consists of the glomerulus and its tubule, and the common collecting system. Each kidney consists of about 1 million nephrons. Different components of a nephron are shown in **Figure 10.1**.



Glomerulus
Distal convoluted tubule
Urine
Proximal convoluted tubule
Collecting duct
Loop of Henle

FIG. 10.1: Different components of the nephron.

Functions of Kidney

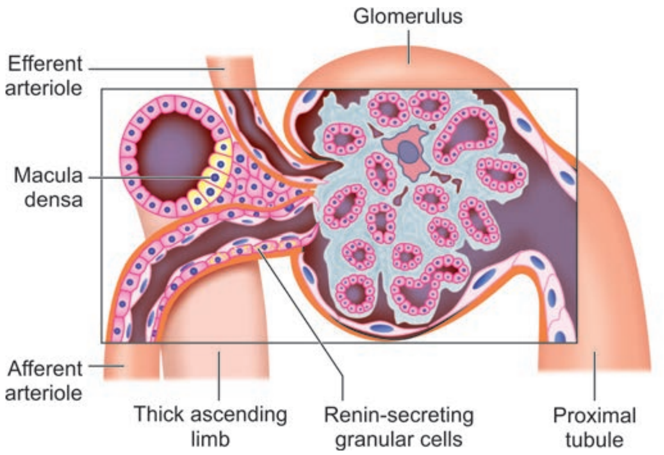
- **Excretion** of many metabolic breakdown products (including ammonia, urea and creatinine from protein, and uric acid from nucleic acids), drugs and toxins
- Regulation of **water and electrolyte balance**
- Maintenance of **acid-base balance**
- **Reabsorption** of essential substances
- Secretion of hormones such as **erythropoietin and renin**
- Metabolism of **vitamin D**
- **Regulation of blood pressure**

Juxtaglomerular Apparatus

Q. Write a short note on the juxtaglomerular apparatus.

Components of juxtaglomerular apparatus (Fig. 10.2): It consists of (1) macula densa, (2) the extraglomerular mesangium, (3) the terminal portion of the afferent glomerular arteriole (contains renin-producing granular cells), and (4) the proximal portion of the efferent arteriole.

1. **Macula densa:** The afferent arterioles and the thick ascending limb of loop of Henle are in contact for a short distance. The macula densa is a plaque of tall and columnar cells within this thick ascending limb of the loop of Henle and contains large, tightly packed cell nuclei (hence termed macula densa). This anatomical arrangement allows changes in the renal tubule to influence the behavior of the adjacent glomerulus (tubuloglomerular feedback).
2. **Extraglomerular mesangium.**



Glomerulus
Efferent arteriole
Macula densa
Afferent arteriole
Thick ascending limb
Renin-secreting granular cells
Proximal tubule

FIG. 10.2: Diagrammatic representation of glomerulus and juxtaglomerular apparatus.

3. **Terminal portion of the afferent glomerular arteriole:** Shows thickening due to specialized myoepithelioid cells (juxtaglomerular cells) that contain large secretory granules of renin.
4. **Proximal portion of the efferent arteriole.**

Renin angiotensin aldosterone system (RAAS)

Renin is **secreted and stored in the juxtaglomerular cells.**

Factors controlling release of renin

- Pressure changes in the afferent arteriole
- Sympathetic tone
- Sodium, chloride, and osmotic concentration of the fluid in the distal convoluted tubule at the macula densa
- Local prostaglandin and nitric oxide release.

Mechanism of action of renin

- **Renin** acts on angiotensinogen in the blood and **converts angiotensinogen to angiotensin I.**
- **Angiotensin I** (decapeptide) is **converted to angiotensin II** (octapeptide) **by angiotensin-converting enzyme (ACE)**, which is present in the lung, luminal border of endothelial cells, glomeruli and other organs.
- **Angiotensin II** has **two major systemic effects: Systemic vasoconstriction** and **sodium and water retention** by release of aldosterone from the adrenal cortex.
- Aldosterone acts in the distal tubule by reabsorbing sodium and secreting potassium via mineralocorticoid receptor produces constriction of the efferent arteriole of the glomerulus and thereby increases glomerular filtration pressure in severe hypotension.

Consequences of renin action

- By above mentioned mechanisms, the kidneys **"defend" circulating blood volume**, **blood pressure, and glomerular filtration during circulatory shock**.
- However, the same mechanisms can lead to systemic hypertension in renal ischemia.

Renin-angiotensin-aldosterone system (RAAS) is presented in **Figure 10.3**.

APPROACH TO RENAL DISEASES

Azotemia

Definition: It is a **biochemical abnormality** characterized by an **elevation of the blood urea nitrogen (BUN) and creatinine** levels. It is mainly due to a decreased glomerular filtration rate (GFR).

Causes: Azotemia can be divided into prerenal, renal, and postrenal (discussed later under AKI section).

Glomerular Filtration Rate (GFR)

- Measurement of the GFR is required to know the exact level of renal function. It is necessary to calculate GFR when the serum (plasma) urea or creatinine is within the normal range.
- Glomerular filtration rate for an average adult is about 125 mL/minute. Formula for calculation of GFR is presented in **Table 10.1**.
- The most common methods utilized to estimate the GFR are—measurement of the creatinine clearance and estimation equations based upon serum creatinine such as the Cockcroft–Gault equation, the Modification of Diet in Renal Disease (MDRD) study equations.

Measurement

$$\text{Renal clearance (C)} = \frac{UV}{P}$$

C = renal clearance, U = urinary concentration of any substance, P = plasma concentration of the same substance, V = minute volume of urine.

Inulin Clearance

- It is the **gold standard but is not practical**.
- Inulin is a polysaccharide that **passes freely through the glomerular capillary wall**. It is **neither absorbed nor excreted by the tubules** and hence, the quantity of inulin excreted in urine (UV) is identical to the amount filtered by the glomeruli. Therefore, the **renal clearance of inulin can be used to measure GFR.**

Creatinine Clearance

Q. Write short note on creatinine clearance and mention the formula for its calculation.

- The measurement of creatinine clearance, which approximates to that of inulin is the **most commonly used for measurement of GFR**. Other substances that are used are iohexol, iothalamate, ^{51}*Cr-EDTA*
- **Principle:** Creatinine clearance is based on the fact that **daily production of creatinine** (mainly from muscle cells) is **remarkably constant** and little affected by protein intake. Thus, serum creatinine and urinary output vary very little throughout the day and renal creatinine clearance given an estimate of the glomerular function of the kidney.
- **Creatinine clearance overestimates GFR**
- **Cockroft–Gault equation:** If serum creatinine level is stable, creatinine clearance (hence GFR) is estimated by using the Cockroft–Gault formula **(Table 10.1)**.

TABLE 10.1: Formulas used to estimate eGFR/creatinine clearance (CrCl).

MDRD		GFR in mL/min per 1.73 $m^2 = 175 \times SCr^{-1.154} \times age^{-0.203} \times 1.212$ (if patient is black) × 0.742 (if female)
Cockroft–Gault		CrCl = [(140 – age) × TBW]/(SCr × 72) (× 0.85 for females)
The Schwartz equation: It is a simple bedside formula to estimate glomerular filtration rate (GFR) in children $\text{GFR (mL/min/1.73 m}^2) = \frac{\text{Height (cm)} \times 55}{\text{SCr (mg/dL)}}$		
CKD-EPI	Male	141 × min (SCr/0.9,1) – 0.411 × max (SCr/0.9,1) – 1.209 × 0.993 Age × (1.159 if black)
	Female	141 × min (SCr/0.7,1) – 0.329 × max (SCr/0.7,1) – 1.209 × 0.993 Age × (1.159 if black) × 1.018

(CKD-EPI: Chronic kidney disease epidemiology collaboration; eGFR: Estimated glomerular filtration rate; MDRD: Modification of diet in renal disease; SCr: serum creatinine)

Cystatin C

Serum cystatin C is reabsorbed totally at the level of proximal tubule and is catabolized at the level of proximal tubule. Hence serum cystatin C can be used for estimation of glomerular filtration rate. It has been theoretically deemed better than creatinine because like creatinine, it is not affected by muscle mass, age, gender, exercise, diet, etc. The serum cystatin C concentration may correlate more closely with the GFR than the serum creatinine concentration.

Renal Function Tests (Table 10.2)

TABLE 10.2: Renal function tests.

Functional integrity	*Test/s performed*
Glomerular function	GFR: Inulin clearance, creatinine clearance, serum urea and creatinine, serum electrolytes, uric acid, and serum osmolality
Renal blood flow	Proteinuria (albumin), para-aminohippuric acid excretion test
Tubular function	Urine osmolality, concentration, and dilution test
	Urine electrolytes, e.g., Na, K, Ca, phosphate, uric acid
	Urine HCO_3, ammonia, pH after acid loading
Structural integrity	
➢ Plain X-ray KUB (kidney, ureter, bladder) ➢ Antegrade and retrograde pyelography ➢ Ultrasound ➢ Renal arteriography	➢ IVP (intravenous pyelogram) ➢ CT scan, CT urogram, MRI ➢ Kidney biopsy

Examination of the Urine

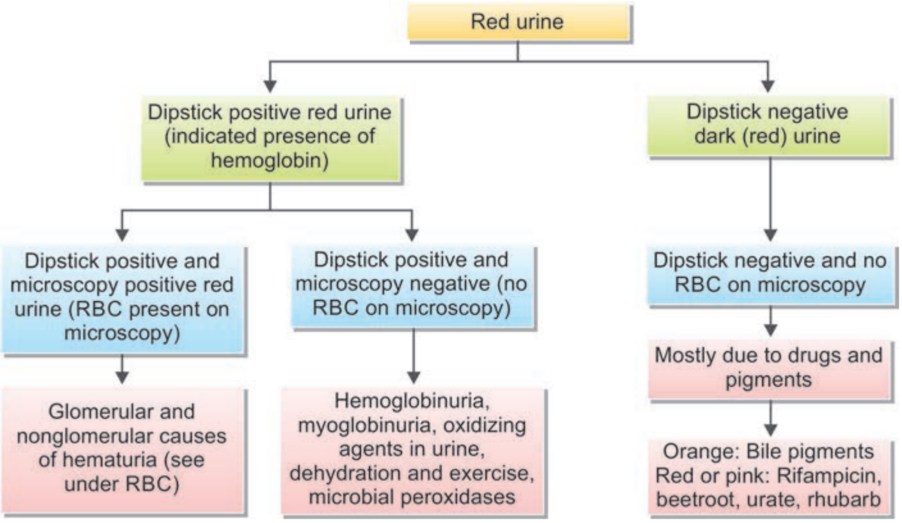
Q. Write short essay on routine examination of urine.

Physical Examination

Appearance: Color and clarity

- **Normal** urine is **straw to amber colored** due to the presence of urochrome pigment, excretion of which is generally proportional to the metabolic rate.
- Urine color interpretation **(Table 10.3)**.
- Approach to red urine **(Flowchart 10.1)**
- Clarity
- Cloudy or turbid urine is most commonly associated with urinary tract infections (UTIs). Turbid white urine is sometimes called as albinuria **(Box 10.1)**.

FLOWCHART 10.1: Approach to red color or dark urine.



Red urine
Dipstick positive red urine (indicated presence of hemoglobin)
Dipstick negative dark (red) urine
Dipstick positive and microscopy positive red urine (RBC present on microscopy)
Dipstick positive and microscopy negative (no RBC on microscopy)
Dipstick negative and no RBC on microscopy
Glomerular and nonglomerular causes of hematuria (see under RBC)
Hemoglobinuria, myoglobinuria, oxidizing agents in urine, dehydration and exercise, microbial peroxidases
Mostly due to drugs and pigments
Orange: Bile pigments
Red or pink: Rifampicin, beetroot, urate, rhubarb

TABLE 10.3: Characteristic urine color.

Color	*Pathological cause*	*Food or drug or dye causing similar discoloration*
Yellow	Normal: Straw yellow Deep yellow: Concentrated urine	Carrots
Red/ orange	Hematuria Hemoglobinuria Myoglobinuria Porphyria	Beetroot ingestion Drugs such as rifampicin, pyridium
Purple	Porphyria	
Black or brown	Melanin Methemoglobin	Chloroquine Levodopa Nitrofurantoin Fava beans
Dark on standing	Porphyria Alkaptonuria (due to homogentisic acid)	

Box 10.1: Causes of turbid urine or albinuria.

- Chyluria
- Filariasis
- Schistosomiasis
- Postsurgery
- Malignancy
- Hyperuricosuria
- Phosphaturia
- Hyperoxaluria
- Proteinuria
- Pyuria
- Lipiduria
- Caseous material from renal tuberculosis
- Congenital malformations of the lymphatic vessels

TABLE 10.4: Characteristic urine odor and condition.

Characteristic urine odor	*Condition*
Musty odor	Phenylketonuria
Sweet or fruity odor	Diabetes, ketosis, maple syrup urine disease
Sweaty foot or acrid odor	Isovaleric acidemia, glutaric acidemia
Rancid/fishy odor	Hypermethionemia
Swimming pool odor	Hawkinsinuria
Cat urine odor	3-hydroxyl 3-methyl glutaric aciduria
Maple syrup	Maple syrup urine disease
Boiled cabbage	Hypermethionemia
Tomcat urine	Multiple carboxylase deficiency
Hops-like urine	Oasthouse urine disease
Rotting fish	Trimethylaminuria

Odor

The characteristic urine odor and condition has been shown in **Table 10.4**.

TABLE 10.5: Causes of oliguria.

Nonrenal conditions	*Renal diseases*
➢ Excess loss of fluid ➢ Hypovolemia ➢ Shock ➢ Congestive heart failure ➢ Cirrhosis ➢ Pancreatitis, sepsis ➢ Peritonitis	➢ Acute glomerulonephritis ➢ Acute tubular necrosis (ATN) ➢ Acute interstitial nephritis ➢ Obstructive nephropathy

Box 10.2: Causes of anuria.

- Obstruction:
  - Bilateral ureteric obstruction
  - Prostatic or urethral obstruction
  - Renal stones
  - Tumors
- **Renal ischemia:** Bilateral renal arterial or venous occlusion
- *All causes of oliguria can lead to anuria.*

Urine Volume

A healthy adult excretes about 600–2,000 mL of urine in 24 hours. Volume is measured by collecting 24-hour urine samples in a measuring cylinder.

Q. Define oliguria, anuria, and polyuria. List the causes.

- **Oliguria:** Decreased production of **urine usually <400 mL** of urine **per day or less than 17 mL/hour.** On an average diet, about 300–500 mL urine/day is required to excrete the solute load at maximum concentration.
  - **Causes of oliguria (Table 10.5)**
- **Anuria:** Anuria is defined as urine output that is less than 100 mL/24 h or 0 mL/12 h. Anuria more commonly suggests reduced production of urine or obstruction to urine flow from both kidneys (until proved otherwise). Bladder outflow obstruction must always be considered first.
  - **Causes of anuria (Box 10.2)**
- **Polyuria:** Polyuria is defined as **persistent large increase in urine volume of >3 L/day and 2 L/m^2 in children.** This term should exclude normal individuals who take large amount of fluid and therefore, form large volumes of urine. Polyuria may be either due to increased urinary solute excretion (osmotic/solute diuresis) or pure water diuresis.
  - **Causes of polyuria (Box 10.3)**

Box 10.3: Causes of polyuria.

- Pathological polyuria:
  - Increased excretion of solute (osmotic diuresis): Glucosuria—hyperglycemia, administration of mannitol, and hypercalcemia. Urea diuresis and sodium diuresis.
  - Defective renal concentrating ability: Diabetes insipidus, papillary necrosis, and diuretic phase of ATN
  - Failure of production of ADH: Idiopathic (50%), mass lesion, trauma, and infection
  - Drugs/toxins: Diuretics, lithium, and alcohol
- Primary (or psychogenic) polydipsia: Excess fluid intake

(ADH: Antidiuretic hormone; ATN: Acute tubular necrosis)

Specific Gravity and Osmolality

Urine specific gravity is used as a measure of the concentrating power of the kidney. It is a measure of the weight of dissolved particles in urine. Urine osmolality reflects the number of dissolved particles.

Normal specific gravity of a 24-hour urine sample is **1.003–1.035**, average being 1.016.

Uses:

- Specific gravity provides information about the renal status and hydration.
- It is used only in the differential diagnosis of oliguric renal failure or the investigation of polyuria or inappropriate ADH secretion.
- **Fixed specific gravity:** When **specific gravity is fixed** at 1.010, this is known as **isosthenuria**. It is indicative of severe renal damage [chronic renal failure (CRF)/chronic kidney disease (CKD)] or acute tubular necrosis (ATN) with disturbance of both the concentrating and diluting abilities of the kidney.

Urinary pH

Normal urine is usually acidic with pH varying from 4.6 to 8. Measurement of urinary pH is not necessary except in the investigation and treatment of renal tubular acidosis (RTA).

Chemical Examination

Urine should be examined for the presence of protein, blood and sugar in all patients suspected of having renal disease.

Q. Write short note on proteinuria and microalbuminuria and their causes.

Proteinuria

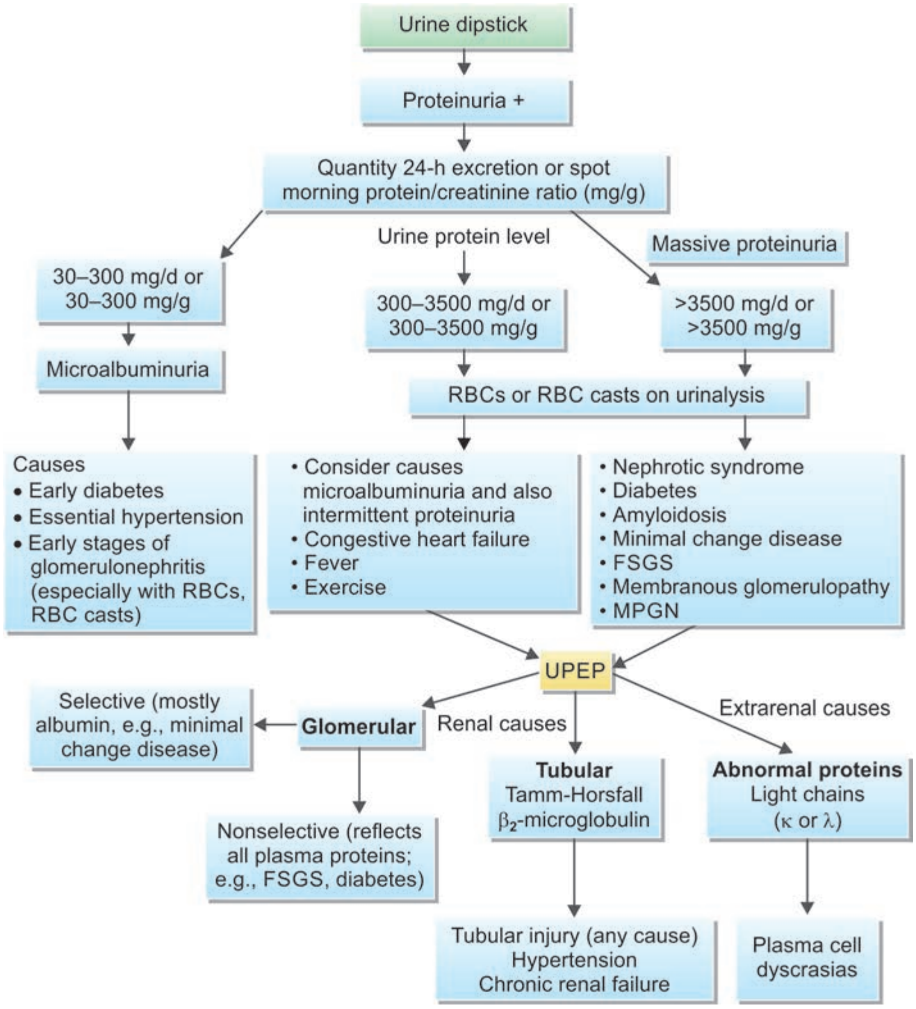
- Healthy adults may daily excrete <150 mg of total proteins and <30 mg of albumin.
- Proteinuria is defined as the **urinary excretion of >150 mg of protein/day.** It is one of the most common signs of renal disease. Pyrexia, exercise, and adoption of the upright posture (*postural proteinuria*) may also increase urinary protein output.

The types of proteinuria and causes are described in **Table 10.6**.

Algorithm approach to proteinuria is presented in **Flowchart 10.2**.

Amount of pathological proteinuria: It may be "mild" (<1.0 g/day), "moderate" (1.0–3.5 g/day) or "massive"/"heavy" (>3.5 g/day). It can be classified as nephrotic range (3.5 g/24 hours) and subnephrotic range (<3.5 g/24 hours, but greater than 500 mg/24 hours).

FLOWCHART 10.2: Algorithm approach to proteinuria.



Urine dipstick
Proteinuria +
Quantity 24-h excretion or spot morning protein/creatinine ratio (mg/g)
Urine protein level
Massive proteinuria
30–300 mg/d or 30–300 mg/g
300–3500 mg/d or 300–3500 mg/g
>3500 mg/d or >3500 mg/g
Microalbuminuria
RBCs or RBC casts on urinalysis
Causes
• Early diabetes
• Essential hypertension
• Early stages of glomerulonephritis (especially with RBCs, RBC casts)
• Consider causes microalbuminuria and also intermittent proteinuria
• Congestive heart failure
• Fever
• Exercise
• Nephrotic syndrome
• Diabetes
• Amyloidosis
• Minimal change disease
• FSGS
• Membranous glomerulopathy
• MPGN
UPEP
Selective (mostly albumin, e.g., minimal change disease)
Glomerular
Renal causes
Extrarenal causes
Nonselective (reflects all plasma proteins; e.g., FSGS, diabetes)
Tubular Tamm-Horsfall β_2-microglobulin
Abnormal proteins Light chains (κ or λ)
Tubular injury (any cause) Hypertension Chronic renal failure
Plasma cell dyscrasias

(FSGS: Focal segmental glomerulosclerosis; MPGN: Membranoproliferative glomerulonephritis; UPEP: Urine protein electrophoresis)

TABLE 10.6: Types of proteinuria and causes.

Types of proteinuria	*Causes*
Transient proteinuria	Fever, heavy exercise, noradrenaline/albumin infusion
Orthostatic proteinuria	Usually in 2–5% of adolescents, rare above age of 30 years
Overflow proteinuria	Myeloma, hemoglobinuria, myoglobinuria
Glomerular proteinuria	Primary glomerular diseases, secondary glomerular diseases, diabetic nephropathy, hypertensive nephrosclerosis
Tubulointerstitial proteinuria	Heavy metal intoxications, autoimmune or allergic interstitial inflammation, drug-induced interstitial injury
Postrenal proteinuria	Urinary tract infections, nephrolithiasis, tumor

Microalbuminuria

- Normal urine contains <30 mg of albumin/day (<20 µg of albumin per minute).
- **Definition:** Microalbuminuria is the **presence of albumin (small amounts) in urine about >30 to <300 mg/day.** It is defined as the persistent elevation of the urinary albumin excretion of 30–200 mg/L (or 20–200 mg/min) in an early morning urine sample. It indicates early and possibly reversible glomerular damage.
- It is so named because conventional dipsticks cannot detect albumin levels of 30–300 mg/day (if urine volume is normal). An increase in albumin excretion between these two levels so-called microalbuminuria.
- **Significance:** The presence of albumin in the urine is a sign of glomerular abnormality.
    - **Diabetes mellitus:**
        - Microalbuminuria is an **early indicator of diabetic glomerular disease**. It is widely used as a predictor of the development of nephropathy in diabetics (raised fractional excretion of magnesium is a more sensitive marker than microalbuminuria in detecting early diabetic nephropathy).
        - In diabetic patients' presence of microalbuminuria is associated with **increased cardiovascular mortality**.
    - Essential hypertension: **In hypertensive patients, microalbuminuria predicts cardiovascular morbidity and mortality.**
    - **Normotensive individuals:**
        - **Risk marker for the presence of cardiovascular disease predicts progression of nephropathy** when it increases to frank albuminuria (>300 mg/day).
        - **Atherosclerosis:** Persistent microalbuminuria is also associated with an increased risk of atherosclerosis and cardiovascular mortality.

Treatment

- Microalbuminuria can be reduced, and its progress to overt proteinuria can be prevented or retarded by **aggressive reduction of blood pressure (especially with ACE inhibitors or angiotensin receptor blockers), and control of diabetes mellitus**.
- **Blood pressure should be maintained at or below 130/80 mm Hg in patients with diabetes or kidney disease.**

Albumin-Creatinine Ratio

Measurement of 24-hour urinary excretion rates provides the most precise measure of microalbuminuria. However, it is often difficult to obtain 24-hour urine, it is more convenient to measure urinary albumin: creatinine ratio in a random urine sample and generally **albumin-creatinine ratio (ACR)** of 2.5–20 corresponds to albuminuria of 30–300 mg daily respectively **(Table 10.7)**. The adequacy of the collection can be estimated by quantifying the 24-hour urine creatinine and comparing this value to the expected urine creatinine.

TABLE 10.7: Classification of proteinuria.

	Dipstick (not accurate)	*Albumin-creatinine ratio (in mg/g)*	*Protein-creatinine ratio (in mg/g)*
Normal to mildly increased *KDIGO A1*	Negative to trace	<30	<150
Moderately increased *KDIGO A2* (Previously microalbuminuria)	Trace to +	30–300	150–500
Severely increased *KDIGO A31* (Previously macroalbuminuria)	+ or greater	>300	>500
Nephrotic-range proteinuria	+++ or ++++	>2,200	>3,500

Tamm–Horsfall Mucoprotein (Uromodulin)

Q. Write short note on Tamm–Horsfall mucoprotein.

- It is a **protein present in normal urine** produced in the thick ascending limb of the loop of Henle. It is excreted at a rate of 25 mg/day.
- Function is not known. Probably it may have some immunomodulatory activity and may protect against UTI.

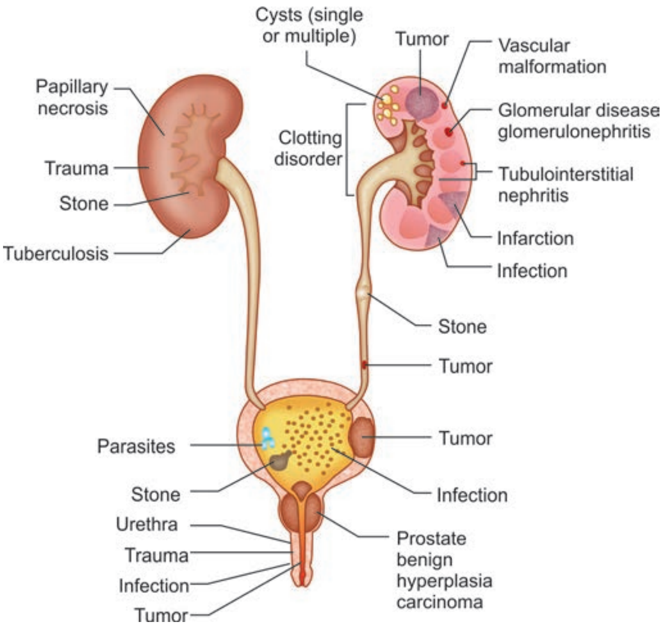
It is a **constituent of all types of urinary casts**. It is involved **in the pathogenesis of cast nephropathy** (observed in renal failure associated with multiple myeloma) in which intratubular casts occlude the flow or urine.

Hematuria

Q. Enumerate the common causes of hematuria/the causes of painless hematuria. How will you clinically localize and evaluate the site of bleeding?

- Hematuria may be visible on gross examination and reported by the patient as bloody urine (**macroscopic**/overt hematuria), or invisible and detected on dipstick/chemical testing of urine [**microscopic** hematuria—three or more red blood cells (RBCs) per high-power field].

- **Site of bleeding:** Bleeding may occur at any site within the urinary tract and common causes of hematuria are illustrated in **Figure 10.4**. Features that may help to localize the site of bleeding in the urinary tract are mentioned in **Table 10.8**.



Cysts (single or multiple)
Tumor
Vascular malformation
Papillary necrosis
Clotting disorder
Glomerular disease glomerulonephritis
Trauma
Tubulointerstitial nephritis
Stone
Tuberculosis
Infarction
Infection
Stone
Tumor
Parasites
Tumor
Stone
Infection
Urethra
Trauma
Prostate benign hyperplasia carcinoma
Infection
Tumor

FIG. 10.4: Sites and common causes of bleeding from the urinary tract.

TABLE 10.8: Probable site of bleeding and its features.

Probable site of bleeding	***Suggestive features***
Urethra	Blood is seen at the start of voiding and then the urine becomes clear
Urinary bladder or above	Blood diffusely present throughout the urine
Glomerular origin	➢ Cola-colored urine ➢ Red-cell casts (glomerulonephritis) ➢ Dysmorphic erythrocytes (irregular outer cell membrane) ➢ Acanthocytes (erythrocytes with one or more membrane protrusions of variable size and shape)
Renal pelvis and lower urinary tract	Pink or red colored urine
Prostate or bladder base	Blood only at the end of micturition
Lower urinary tract origin	➢ Isomorphic erythrocytes in urine ➢ Microscopic clots of clumped erythrocytes in urine

Causes of Painless Hematuria

See **Table 10.9**

TABLE 10.9: Causes of painless hematuria.

Site of hematuria	***Causes***
Kidney	➢ Glomerulonephritis, IgA nephropathy ➢ Pyelonephritis: Severe acute pyelonephritis, papillary necrosis (more common in diabetes mellitus and sickle cell trait or disease) ➢ Tumors: Renal cell carcinoma ➢ Others: Infective endocarditis, renal tuberculosis, benign familial hematuria, microscopic polyangiitis, Wegener's granulomatosis
Ureter	Neoplasms
Bladder	Neoplasms, trauma, schistosomiasis
Prostate	Prostatitis, neoplasms
Urethra	Trauma

Glycosuria

- Blood glucose level varies between 70 and 120 mg/dL. This may increase to 120–160 mg/dL after a meal. Normally, all the glucose in the blood is filtered through the glomerulus and reabsorbed at the proximal tubules.
- If the renal threshold (the lowest blood glucose level that will result in glycosuria) is exceeded (usually >180–200 mg/dL), the excess glucose will not be reabsorbed into the blood and will be eliminated in the urine as in cases of diabetes mellitus. The presence of detectable amounts of **glucose in urine** is termed **glycosuria**.
- Drugs such as sodium-glucose transport protein 2 (SGLT2) inhibitors, uncontrolled diabetes, focal segmental glomerulosclerosis (FSGS), tubular dysfunction [proximal renal tubular acidosis (RTA)] can cause glycosuria.

Bacteriuria

Dipstick tests used for detection of bacteriuria detect nitrite produced from the reduction of urinary nitrate by bacteria. It is also for the detection of leukocyte esterase, an enzyme specific for neutrophils. *Enterobacteriaceae* species elaborate the enzyme nitrate reductase, which confers the ability to convert urinary nitrate to nitrite. So, nitrite-positive urine may indicate bacteriuria.

Microscopy

Microscopic examination of urine should be done in all patients suspected of having renal disease, on a "clean" midstream sample.

Cells

They are expressed as number of cells per low power or high power field.

- **Red blood cells:** Presence of RBCs (more than 3/hpf) in the urine indicates bleeding at any point in the urinary system from the glomerulus to the urethra. In glomerular diseases, the urine show red cells with cellular protrusions or fragmentation and are named as **dysmorphic** (distorted morphology) RBCs.
- **White blood cells:** Increased number of WBCs (mainly neutrophils more than 5/hpf) in urine is known as **pyuria**. It is indicative of an inflammatory reaction within urinary tract such as UTI, stones, tubulointerstitial nephritis (TIN), papillary necrosis, tuberculosis, and interstitial cystitis. The causative organism of infection may be identified by bacteriological examination. When accompanied by **leukocyte casts** or mixed leukocyte–epithelial cell casts, increased urinary leukocytes are considered to be of **renal origin.**

Patient's Evaluation of Hematuria

Investigations

- **Urine examination:**
  - ■ **Proteinuria**
  - ■ **Culture of urine for acid-fast bacilli**
  - ■ **Microscopy:**
    - ♦ **Morphology of RBC** (assessed by phase contrast microscopy of fresh urine)
    - ♦ **Urine cytology:** For malignant cells especially in patients with risk factors such as smoking, analgesic abuse, industrial toxin exposure (e.g., aniline, benzidine, aromatic amines), age >50 years, irradiation, urinary schistosomiasis
- **Renal function tests**
- **Blood:**
  - ■ Platelet count
  - ■ Coagulation studies
  - ■ Autoantibodies (antinuclear antibody, antineutrophil cytoplasmic antibody)
- **Radiological investigations:**
  - ■ **Ultrasound for kidneys, ureters, bladder and prostate, CT, MRI**
  - ■ Intravenous pyelography
- **Cystourethroscopy**

Casts

Casts are one of the organized elements which are **formed only in the kidney** and are **indicative of a renal disease.** They are cylindrical bodies, molded in the shape of the distal tubular lumen formed by solidification of **Tamm–Horsfall protein**, a glycoprotein secreted in the distal convoluted tubules and collecting tubules. These proteins form a fibrillar meshwork (basic matrix) and can trap any elements including cells, cell fragments or granular material.

Types of urinary casts and their significance

See **Figure 10.5.**

Cast and its appearance	Significance
Hyaline cast 	• Nonspecific. Present in normal urine • Acute glomerulonephritis (AGN) • Chronic glomerulonephritis (CGN) • Fever • Congestive heart failure
Waxy cast 	• End stage kidney • Chronic/advanced renal failure • Amyloidosis
Cellular casts	
1. Red blood cell (RBC) cast 	• Always indicates renal disease • AGN • Lupus nephritis • Goodpasture syndrome • Subacute bacterial endocarditis • Renal infarction
2. Leukocyte (WBC) cast 	• Acute pyelonephritis • AGN (proliferative glomerulonephritis) • Interstitial nephritis
3. Epithelial cast 	• Acute tubular necrosis/injury • Viral disease (e.g. cytomegalovirus disease) • Drug • Interstitial nephritis • Transplant rejection
Granular cast (finely or coarsely granular)	
Coarsely granular 	• Tubular damage • CGN • Nephritis with tubular injury • Renal failure
Finely granular 	
Fatty cast 	• Nephrotic syndrome • Fabry's disease • Other nephritidis
Telescoped (mixed) sediment 	• Proliferative GN (systemic lupus erythematosus, polyarteritis nodosa) • Hypersensitivity reaction • Subacute bacterial endocarditis
Bacterial cast 	• Diagnostic of acute bacterial pyelonephritis • Intrinsic renal infections
Broad cast (renal failure casts) 	• Progressive renal failure with compensatory hypertrophy of nephron (poor prognosis)

FIG. 10.5: Urinary casts and their significance.

Crystals (Figs. 10.6A to C)

They may be found in patients with renal calculi. Calcium oxalate and urate crystals can be found in normal urine that has been left to stand.

Crystal in normal acidic urine	Condition
Amorphous urates 	• Normal acidic urine • Concentrated urine as in fever and dehydration
Crystalline urates (sodium, potassium and ammonium) 	Normal acidic urine
Crystalline uric acid 	• Normal acidic urine • Post-chemotherapy for lymphoma and leukemia
Calcium oxalate 	• Normal acidic urine • Large numbers in severe chronic renal disease or ethylene glycol or methoxyflurane toxicity/ poisoning • Nephrolithiasis

FIG. 10.6A: Normal crystals found in acidic urine.

Crystal in normal alkaline urine	
Amorphous phosphates 	Calcium carbonate Ammonium biurate crystals 	Crystalline phosphates-triple phosphates 
Crystalline phosphates-triple phosphates: It may be found in normal alkaline urine
- Struvite stones (magnesium, ammonium, phosphate) due to urease positive bacteria
- Urinary tract infection

FIG. 10.6B: Normal crystals found in alkaline urine.

Abnormal crystal	Condition
Cystine 	• Cystinuria and may be associated with cystine calculi
Tyrosine 	• Tyrosinuria • Occasionally with severe liver disease
Leucine 	• Leucine and tyrosine crystals may occur together and are associated with severe liver disease

Other crystals	
Cholesterol 	Hemosiderin Bilirubin 	Sulphonamide 
FIG. 10.6C: Abnormal crystals found in urine.

ACUTE KIDNEY INJURY (ACUTE RENAL FAILURE)

Q. IM10.2 Classify, describe and differentiate the pathophysiologic causes of acute renal failure.

Renal failure is the failure of renal excretory function due to reduced GFR. Acute kidney injury (AKI) was previously known as acute renal failure (ARF). The other term used for this is **azotemia**.

Definition

Acute kidney injury is a clinical syndrome, defined as an **abrupt, deterioration of kidney function**, which is usually, but not invariably, reversible over a period of days or rarely over a few weeks. The deterioration in renal function is sufficiently severe to result in retention of nitrogenous wastes in the body (uremia) and other waste products normally cleared by the kidneys.

- It is **usually** but not invariably accompanied by **oliguria**.
- Conventionally the term ARF is often used in reference to the subset of patients with a need for acute dialysis support.

Classification of Acute Kidney Injury

Acute kidney injury is a medical emergency. It may produce sudden, life-threatening biochemical disturbances. ***AKI includes an increase in serum creatinine by ≥0.3 mg/dL (27 μmol/L) within 48 hours or an increase to ≥1.5 times the presumed baseline value that is known or presumed to have occurred within the prior 7 days, or a decrease in urine volume to <3 mL/kg over 6 hours*** [Kidney Disease: Improving Global Outcomes (KDIGO)-AKI].

RIFLE Criteria (Table 10.10)

- The distinction between acute and CKD or acute on chronic kidney disease, cannot easily be done in case of uremia. Acute Dialysis Quality Initiative group proposed the **RIFLE** (**R**isk, **I**njury, **F**ailure, **L**oss, **E**nd-stage renal disease) **criteria** to classify AKI.
- These criteria indicate an increasing degree of renal damage are of predictive value for mortality.

TABLE 10.10: RIFLE criteria for classification of acute kidney injury.

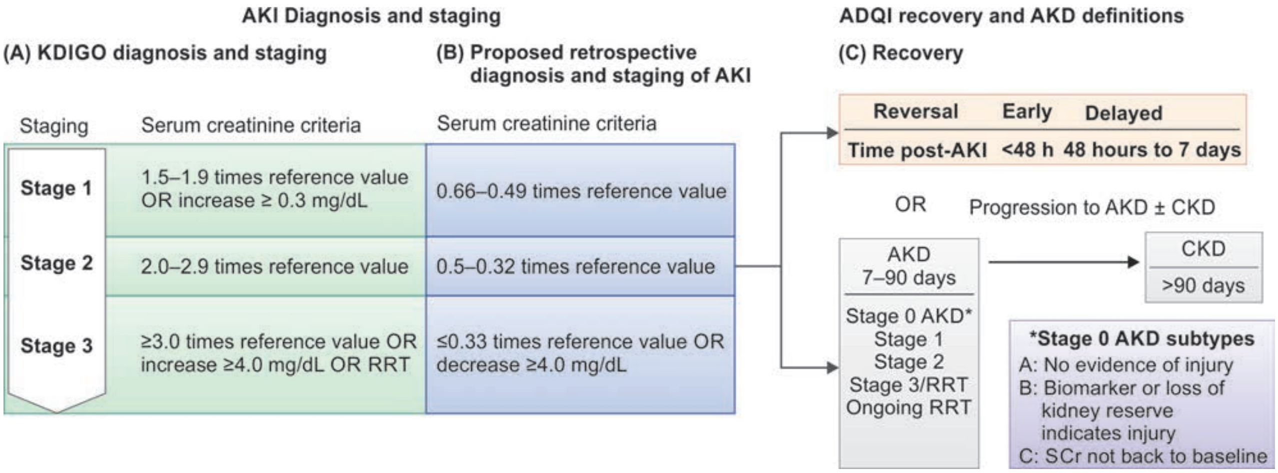
Grade	*GFR criteria*	*Urine output criteria*
Risk (Stage 1)	Increased serum creatinine × 1.5 times within 48 hours	Urine output <0.5 mL/kg/hour × 6 hours
Injury (Stage 2)	Increased serum creatinine × 2–3 times	Urine output <0.5 mL/kg/hour × 12 hours
Failure (Stage 3)	Increased serum creatinine × 3 times or serum creatinine (acute rise of = 0.5 mg/dL)	Urine output <0.3 mL/kg/hour × 24 hours OR Anuria for 12 hours OR Initiation of renal replacement therapy
Loss	Persistent AKI = Complete loss of renal function >4 weeks	
End-stage kidney disease	Persistent renal failure >3 months	

(GFR: Glomerular filtration rate)

Acute Kidney Injury Network Classification

Acute kidney injury network **(AKIN)** has proposed a modification of the RIFLE criteria. It includes less severe AKI, a time constraint of 48 hours, and gives a correction for volume status before classification. According to this, AKI is classified into **three stages:**

- **Stage 1** is same as risk category of RIFLE with **addition of increase in serum creatinine by 0.3 mg/dL** within 48 hours.
- **Stages 2 and 3 are same as** injury and failure categories of **RIFLE**.



AKI Diagnosis and staging
(A) KDIGO diagnosis and staging
(B) Proposed retrospective diagnosis and staging of AKI
Staging
Serum creatinine criteria
Serum creatinine criteria
Stage 1
1.5–1.9 times reference value OR increase ≥ 0.3 mg/dL
0.66–0.49 times reference value
Stage 2
2.0–2.9 times reference value
0.5–0.32 times reference value
Stage 3
≥3.0 times reference value OR increase ≥4.0 mg/dL OR RRT
≤0.33 times reference value OR decrease ≥4.0 mg/dL

Etiopathogenesis

Causes

Q. Write short essay/note on causes of acute renal failure/acute kidney injury.

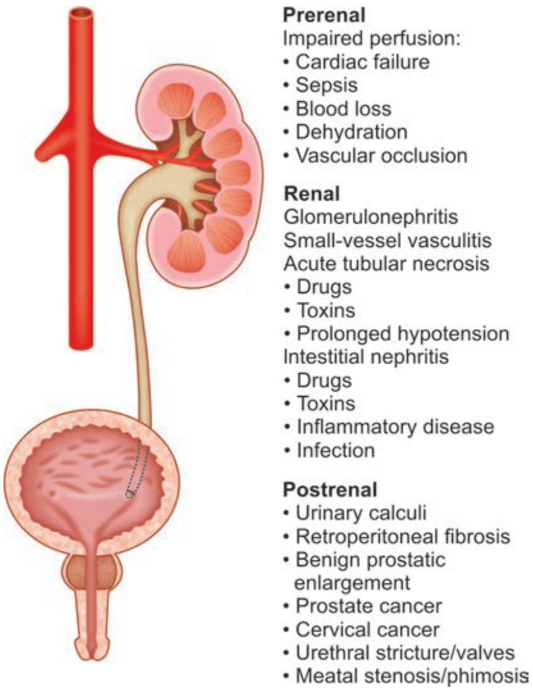
At rest normal kidney receives about 25% of the cardiac output. The etiology of AKI is diverse.

Classification (Table 10.11 and Fig. 10.7)

Q. IM10.3 Describe the pathophysiology and causes of prerenal ARF, renal and postrenal ARF.

Causes of AKI are traditionally divided into three broad anatomical categories: Prerenal, intrarenal (intrinsic renal parenchymal disease), and postrenal causes. Most common cause is **ATN followed by prerenal causes.**

- **Prerenal causes:**
  - Precipitating event is **renal hypoperfusion** which may be due to **reduction in the volume of extracellular fluid** or disease states associated with decreased effective arterial volume or other causes.
  - Kidneys are inadequately perfused and the GFR is markedly reduced and produces oliguria (urine output <400 mL/day).
- **Renal causes:**
  - **Intrinsic diseases of kidney** causing AKI are classified according to the primary histologic site of injury: **Tubules, interstitium, vasculature or glomerulus**.
  - **Renal tubular epithelial (RTE) cell injury**, commonly known as **acute tubular necrosis** (ATN) and occurs more commonly due to ischemia of any cause, but can also be damaged by specific renal toxins. ATN results in ischemia and necrosis of the tubular epithelial cells. However, when the causative factors are removed the tubular cells can regenerate.
- **Postrenal causes:** These include obstruction of the urinary tract at any point in its course from the tubule to the urethra.



Prerenal
Impaired perfusion:
• Cardiac failure
• Sepsis
• Blood loss
• Dehydration
• Vascular occlusion
Renal
Glomerulonephritis
Small-vessel vasculitis
Acute tubular necrosis
• Drugs
• Toxins
• Prolonged hypotension
Intestitial nephritis
• Drugs
• Toxins
• Inflammatory disease
• Infection
Postrenal
• Urinary calculi
• Retroperitoneal fibrosis
• Benign prostatic enlargement
• Prostate cancer
• Cervical cancer
• Urethral stricture/valves
• Meatal stenosis/phimosis

FIG. 10.7: Causes of acute kidney injury.

TABLE 10.11: Classification of causes of acute kidney injury.

Category	*Abnormality*	*Possible causes*
Prerenal	Hypovolemia	➢ Hemorrhage ➢ Volume depletion ➢ Renal fluid loss (over-diuresis) ➢ Third space (burns, peritonitis, muscle trauma)
	Impaired cardiac function	➢ Congestive heart failure ➢ Acute myocardial infarction ➢ Massive pulmonary embolism
	Systemic vasodilatation	➢ Antihypertensive medications ➢ Gram-negative bacteremia ➢ Cirrhosis ➢ Anaphylaxis
	Increased vascular resistance	➢ Anesthesia ➢ Surgery ➢ Hepatorenal syndrome ➢ NSAID medications ➢ Drugs that cause renal vasoconstriction (i.e., cyclosporine)
Intrinsic	Tubular	➢ Renal ischemia (*shock, complications of surgery, hemorrhage, trauma, bacteremia, pancreatitis, pregnancy*) ➢ Nephrotoxic drugs (*antibiotics, antineoplastic drugs, contrast media, organic solvents, anesthetic drugs, heavy metals*) ➢ Endogenous toxins (*myoglobin, hemoglobin, uric acid*)
	Glomerular	➢ Acute postinfectious glomerulonephritis ➢ Lupus nephritis ➢ IgA glomerulonephritis ➢ Infective endocarditis ➢ Goodpasture syndrome ➢ Wegener disease
	Interstitium	➢ Infections (*bacterial, viral*) ➢ Medications (*antibiotics, diuretics, NSAIDs, and many more drugs*)

Contd...

Contd...

Category	*Abnormality*	*Possible causes*
	Vascular	➢ Large vessels (*bilateral renal artery stenosis, bilateral renal vein thrombosis*) ➢ Small vessels (*vasculitis, malignant hypertension, atherosclerotic or thrombotic emboli, hemolytic uremic syndrome, thrombotic thrombocytopenic purpura*)
Postrenal	Extrarenal obstruction	➢ Benign prostate hypertrophy ➢ Improperly placed catheter ➢ Bladder, prostate or cervical cancer ➢ Retroperitoneal fibrosis
	Intrarenal obstruction	➢ Nephrolithiasis ➢ Blood clots ➢ Papillary necrosis

(IgA: Immunoglobulin A; NSAIDs: Nonsteroidal anti-inflammatory drugs).

Clinical Features (Table 10.12)

General Symptoms

- Irrespective of the cause ARF present with symptoms related to uremia. These include **anorexia, nausea, vomiting, intellectual clouding, drowsiness, fits, coma, pruritus, hemorrhagic episodes** (e.g., epistaxis and gastrointestinal hemorrhage), and **dyspnea** due to fluid overload.
- **Physical findings** include asterixis, myoclonus, pericardial rub, and evidence of fluid overload in the form of edema, elevated jugular venous pressure (JVP), and crepitation.

TABLE 10.12: Clinical features of acute kidney injury.

Type of acute kidney injury	*History findings*	*Physical examination findings*
Prerenal	➢ Volume loss (e.g., history of vomiting, diarrhea, diuretic overuse, hemorrhage, burns) ➢ Reduced fluid intake ➢ Cardiac disease ➢ Liver disease	➢ Orthostatic hypotension and tachycardia ➢ Poor skin turgor ➢ Dilated neck veins, S3 heart sound, pulmonary rales, peripheral edema ➢ Ascites, caput medusae, spider angiomas
Intrinsic renal		
Acute tubular necrosis	History of receiving nephrotoxic medications (including over-the-counter, illicit, and herbal), hypotension, trauma or myalgias suggesting rhabdomyolysis, recent exposure to radiographic contrast agents	Muscle tenderness, compartment syndrome, assessment of volume status
Glomerular	Lupus, systemic sclerosis, rash, arthritis, uveitis, weight loss, fatigue, hepatitis C virus infection, human immunodeficiency virus infection, hematuria, foamy urine, cough, sinusitis, hemoptysis	Periorbital, sacral, and lower-extremity edema, rash, oral/nasal ulcers, hypertension
Interstitial	Medication use (e.g., antibiotics, proton pump inhibitors), rash, arthralgias, fever, infectious illness	Fever, drug-related rash (skin) eosinophilia
Vascular	Nephrotic syndrome, trauma, flank pain, anticoagulation (atheroembolic disease), vessel catheterization or vascular surgery	Skin changes, livedo reticularis, fundoscopic examination (showing malignant hypertension), abdominal bruits
Postrenal	Urinary urgency or hesitancy, gross hematuria, polyuria, stones, medications, cancer	Bladder distention, pelvic mass, prostate enlargement

Q. Describe clinical and laboratory differences between prerenal and renal azotemia.

AKI Due to a Prerenal Disorder

- Most common form of AKI
- Rise in serum creatinine/BUN due to inadequate renal plasma flow and intraglomerular hydrostatic pressure to support normal glomerular filtration.
- Usually no or reversible parenchymal injury, but may be associated with ATN.
- Renin-angiotensin-aldosterone system responds to decreased effective circulating volume, but renal autoregulation fails once systolic blood pressure falls below 80 mm Hg.
- Nonsteroidal anti-inflammatory drugs—prevent renal afferent vasodilatation.
- Angiotensin-converting enzyme inhibitors/angiotensin receptor blockers (ACEIs/ARBs)—prevent renal efferent vasoconstriction.

Q. IM10.4 Describe the evolution, natural history and treatment of ARF.

ARF Due to Renal Causes

Most common causes—sepsis, ischemia, and nephrotoxins. Prerenal AKI can lead to ATN in some cases.

Acute tubular necrosis is the most important cause of ARF due to intrinsic renal diseases. The clinical course in ATN/ARF is divided into three phases:

1. **Oliguric (initiation) phase:**
    - Clinical features depend on the initiating event that caused the ischemic form of AKI. Patients develop symptoms due to fluid overload and azotemia. Fluid overload results in raised JVP, pedal edema, ascites, and pulmonary edema.
    - Mild reduction of urine output and increase in BUN. Hyperkalemia occurs commonly during this phase. This phase usually **lasts for about 10–14 days**. About 40% of the patients may have normal urine output and is called nonoliguric renal failure. The electrolyte disturbances are less in these patients.
2. **Maintenance phase***:* During this phase, there is sustained decrease in urine output in the range of 40–400 mL/day (**oliguria**), **salt and water overload, rising BUN level, hyperkalemia, metabolic acidosis, and other features of uremia**. This phase lasts for days to weeks.
3. **Diuretic (recovery) phase:** During this phase there is a **steady increase in urine output** and in a few days the patient develops **polyuria with a urine output that may reach up to 3 L/day**. During this phase the tubular concentrating capacity is defective, and there is uncontrolled loss of large amounts of water, sodium, and potassium (leading to **hypokalemia**) in the urine. Once the renal tubular function returns to normal, BUN, creatinine levels, and urine volume also return to normal.
    - ARF due to glomerulonephritis (GN) presents with hypertension, proteinuria, and hematuria.
    - Drug-induced acute tubule-interstitial nephritis patients may present with fever, skin rash, and arthralgia.

Ischemia—associated AKI

- Kidneys receive 20% of cardiac output, account for 10% of oxygen consumption although they constitute only 0.5% of human body mass.
- Renal outer medulla is one of the most hypoxic regions in the body—due to the architecture of blood vessels that supply tubules.
- Enhanced leukocyte-endothelial interactions in small vessels causing inflammation
- This causes:
    - Reduced blood flow to metabolically active S3 segment of proximal tubule
    - Mitochondrial dysfunction and release of reactive oxygen species (ROS) leading to tubular injury

Exogenous toxins—contrast agents

- Iodinated contrast agents (CT):
    - Risk of contrast nephropathy increased in presence of CKD, diabetic nephropathy, multiple myeloma, congestive cardiac failure (CCF).
    - Diagnosis: Rise in serum creatinine within 24–48 hours following exposure, peak at 3–5 days, resolving within 1 week.
    - Severe dialysis requiring AKI only occurs in the setting of other coexisting conditions mentioned above.
- Others: High-dose gadolinium (MRI), oral sodium phosphate solutions (bowel purgatives), drugs

Endogenous toxins

- **Rhabdomyolysis**—traumatic crush injuries, muscle ischemia during vascular/orthopedic surgery, compression during come/immobilization, prolonged seizure activity, excessive exercise, heat stroke, malignant hyperthermia, infections, metabolic disorders such as hypophosphatemia and severe hypothyroidism, myopathies—release of **myoglobin**.
- Massive hemolysis—release of **hemoglobin**.
- **Tumor lysis syndrome**—after initiation of cytotoxic therapy (lymphoma, ALL, myeloma)

AKI Due to Postrenal Causes

- Partial or total obstruction to unidirectional flow of urine—leading to increased hydrostatic pressure and interference with glomerular filtration
- Obstruction can be anywhere from renal pelvis to tip of urethra
- Bilateral renal obstruction or unilateral obstruction of a single functioning kidney, setting of CKD, reflex vasospasm of contralateral kidney.
- Causes:
    - Bladder neck obstruction—prostate disease, neurogenic bladder, and therapy with anticholinergic drugs.
    - Obstructed Foley's catheter

  - Ureteric obstruction—intraluminal obstruction—calculi, blood clots, sloughed renal papillae; infiltration of ureteric wall—neoplasia; external compression—retroperitoneal fibrosis, neoplasia, abscess, and surgical damage.
- If untreated, obstructive nephropathy leads to irreversible tubulointerstitial fibrosis (i.e., intrinsic disease).

Investigations

Serum Creatinine and Urea

- The rate of rise in serum creatinine and urea is determined by the rate of protein catabolism (tissue breakdown).
- **Raised serum creatinine and urea** levels are the most consistent findings. In ARF due to prerenal causes, there is a disproportionate elevation of serum urea in relation to serum creatinine.

Q. List the causes of raised serum creatinine (Box 10.4).

Box 10.4: Causes of raised serum creatinine.

- Azotemia: Prerenal, renal, and postrenal
- Large amount of consumption of meat
- Hypothyroidism, acromegaly, and gigantism
- Rhabdomyolysis
- Drugs: Statins, fibrates

Drawbacks: Rise in creatinine is an unreliable indicator of early renal injury because:

- Normal **serum creatinine level is an influenced by several nonrenal factors** (age, gender, muscle mass, medications, hydration and nutrition status, and tubular secretion).
- **More than 50% loss of renal function must be lost before serum creatinine rises.**

Newer Novel Biomarkers for AKI

These markers can diagnose early AKI and include (1) neutrophil gelatinase-associated lipocalin (NGAL), (2) kidney injury molecule-1 (KIM-1), (3) interleukin-18 (IL-18), and (4) cystatin C.

- **Serum creatinine does not reflect true GFR**. This is because several hours to days must elapse before a new equilibrium between presumably steady state production and decreased excretion of creatinine is established.

Other Investigations

- **Other biochemical findings:** Include **hyperkalemia, hypocalcemia, hyperphosphatemia, and hyperuricemia**.
- **Urine analysis (Tables 10.13 and 10.14)**
  - RBCs/RBC casts: Glomerulonephritis, vasculitis, malignant hypertension, and thrombotic microangiopathy
  - WBCs/WBC casts: Interstitial nephritis, GN, pyelonephritis, allograft rejection, and malignant infiltration of kidney
  - Renal tubular epithelial cells/RTE casts/pigmented casts: ATN, TIN, acute cellular allograft rejection, myoglobinuria, hemoglobinuria
  - Granular casts: ATN, GN, TIN, and vasculitis
  - Eosinophiluria: Allergic interstitial nephritis, atheroembolic disease, pyelonephritis, cystitis, GN
  - Crystalluria: Acute uric acid nephropathy, calcium oxalate (ethylene glycol intoxication), drugs/toxins (acyclovir, indinavir, sulfadiazine, and amoxicillin)

TABLE 10.13: Urine finding in different types of acute kidney injury.

Type of acute kidney injury	*Urine findings*
Prerenal	Normal or hyaline casts
Intrarenal Tubular cell injury	Muddy-brown, granular, epithelial casts
Interstitial nephritis	Pyuria, hematuria, mild proteinuria, granular, and epithelial casts, eosinophils
Glomerulonephritis	Hematuria, marked proteinuria, red blood cell casts, granular casts
Vascular disorders	Normal or hematuria, mild proteinuria
Postrenal	Normal or hematuria, granular casts, pyuria

TABLE 10.14: Urinary abnormalities in ARF.

	Prerenal	*Renal*	*Postrenal*
Specific gravity	>1.020	1.010	—
Urine osmolality (mOsm/kg)	>500	250–300	400
Urine/plasma osmolality	>1.1	1–1.1	1–1.1
Urinary sodium (mEq/L)	<20	>40	<30
FENa	<1%	>1%	Variable
Urine/plasma creatinine	>40	<20	<20
Renal failure index	<1	>2	>2
Urinary sediment	Scanty	Active	Scanty
Urinary proteins	Minimal	Moderate to severe	Minimal

(FENa: Fractional excretion of sodium)

- **Proteinuria:**
  - Mild—<1 g/day—ischemia or nephrotoxin associated AKI
  - Moderate—multiple myeloma, atheroemboli
  - Severe (nephrotic range) >3.5 g/day—GN, vasculitis, toxins that affect both glomerulus and tubulointerstitium such as NSAIDs, minimal change disease

- **Electrocardiogram:** May show features of hyperkalemia.
- **Chest radiograph:** May show pulmonary edema and pleural effusion.
- **Others:**
  - **In rapidly progressive glomerulonephritis (RPGN):** Systemic causes (e.g., Wegener's granulomatosis) must be excluded by appropriate investigations (e.g., cAN-CA). A **kidney biopsy may be necessary**.
  - **In postrenal ARF:** Renal imaging by plain abdominal X-ray and ultrasonography may be useful.
  - Kidney injury molecule 1 (KIM 1): Ischemia or nephrotoxin associated AKI
  - Neutrophil gelatinase-associated lipocalin (NGAL): Cardiopulmonary bypass-associated AKI
  - Insulin-like growth factor-binding protein 7 (IGFBP7): Marker of development of severe AKI
  - Tissue inhibitor of metalloproteinase-2 (TIMP-2): Marker of development of severe AKI
  - **Fractional excretion of sodium (Table 10.15): The** ratio of sodium clearance to creatinine clearance, increases the reliability of this index. However, it may remain low in some renal diseases. Fraction of filtered sodium load that is reabsorbed by the tubules—measure of kidney's ability to reabsorb sodium as well as endogenously and exogenously administered factors that affect tubular reabsorption.

  Helps in differentiating between prerenal azotemia and ATN, but has limited role.

TABLE 10.15: Values of FENa (fractional excretion of sodium) and BUN-to-serum creatinine ratio in various causes of acute kidney injury.

Etiology of acute kidney injury	***FENa***	***BUN-to-serum creatinine ratio***
Prerenal	<1%	>20
Intrarenal		<10–15
➤ Tubular necrosis	≥1%	
➤ Interstitial nephritis	≥1%	
➤ Glomerulonephritis (early)	<1%	
➤ Vascular disorders (early)	<1%	
Postrenal	≥1%	>20

(BUN: Blood urea nitrogen)

Complications of Acute Kidney Injury (Box 10.5)

Q. Mention the complications of acute kidney injury (acute renal failure).

Box 10.5: Complications of acute kidney injury.

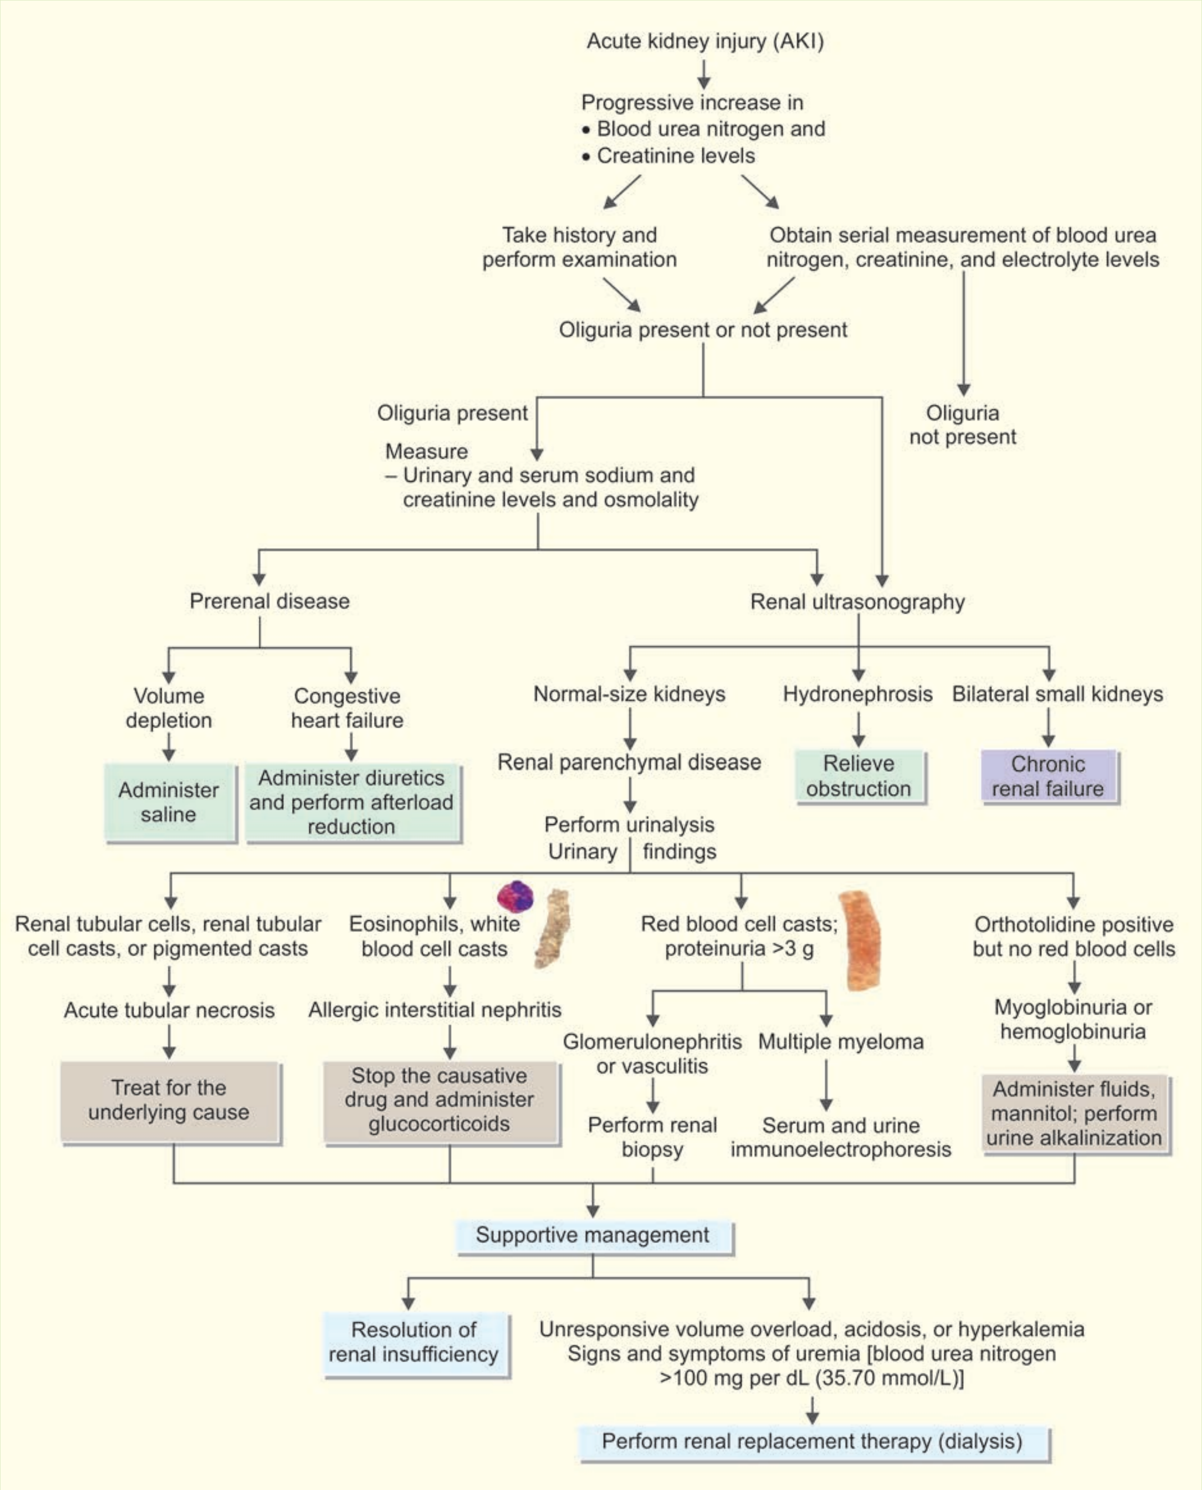
- **Metabolic:** Hyperkalemia, hypocalcemia, hyperphosphatemia, hypermagnesemia, hyperuricemia, metabolic acidosis (increased anion gap)
- **Cardiovascular:** Cardiac arrhythmias, pulmonary edema, pericarditis/pericardial effusion
- **Gastrointestinal:** Gastrointestinal hemorrhage
- **Neurologic:** Encephalopathy, neuropathy, seizures
- **Hematologic:** Anemia, bleeding—platelet dysfunction
- **Miscellaneous:** Infections (pneumonia, urinary tract infection, septicemia)

Management (Flowchart 10.3)

General measures and management of complications:

- **Fluid balance:** Advisable to **restrict fluid intake**.
  - Amount of fluid to be given **depends upon** the **degree of edema**, **and fluid loss** through urine, gastrointestinal tract and skin.
  - Usually intake restricted to about **400 mL/day** in addition to the abovementioned fluid losses.
- **Sodium balance: Sodium is restricted** to avoid volume expansion and overhydration
  - **Hyponatremia** is common and is usually **due to excessive fluid administration**.
  - Hypernatremia may occur occasionally, due to excessive administration of sodium bicarbonate for correction of acidosis.
- **Potassium balance: Hyperkalemia is the leading cause of death** in ARF. Treatment is discussed in Chapter 11.
- **Acid-base balance:** In most patients **acidosis** is of moderate degree and does not require treatment. However, in **advanced cases intravenous sodium bicarbonate** may be necessary. Acidosis if accompanied by severe hyperkalemia and fluid overload is best treated with dialysis.
- **Calcium-phosphorus balance:** Both **hypocalcemia and hypercalcemia** are observed **in the maintenance phase** of ARF and are not serious clinical problems. **Phosphate retention** occurs in patients can be **controlled with aluminum hydroxide, lanthanum carbonate, sevelamer, calcium acetate or calcium carbonate** [bind phosphate within the gastrointestinal tract (GIT) and eliminated in stool].
- **Diet:**
  - **Restrict dietary proteins** to about 40 g/day. Suppress endogenous protein catabolism to a minimum level by giving as much energy as possible in the form of carbohydrates and fats. Patients treated by blood purification techniques are given 70 g or more protein/day.
  - **Hypercatabolic patients** may **need higher nitrogen intake** to prevent negative nitrogen balance.
  - **Restrict the salt intake**.
  - **Vitamin supplements** are usually necessary.

FLOWCHART 10.3: Approach to acute kidney injury.



Acute kidney injury (AKI)
Progressive increase in
• Blood urea nitrogen and
• Creatinine levels
Take history and perform examination
Obtain serial measurement of blood urea nitrogen, creatinine, and electrolyte levels
Oliguria present or not present
Oliguria present
Measure
– Urinary and serum sodium and creatinine levels and osmolality
Oliguria not present
Prerenal disease
Renal ultrasonography
Volume depletion
Congestive heart failure
Administer saline
Administer diuretics and perform afterload reduction
Normal-size kidneys
Hydronephrosis
Bilateral small kidneys
Renal parenchymal disease
Relieve obstruction
Chronic renal failure
Perform urinalysis
Urinary findings
Renal tubular cells, renal tubular cell casts, or pigmented casts
Eosinophils, white blood cell casts
Red blood cell casts; proteinuria >3 g
Orthotolidine positive but no red blood cells
Acute tubular necrosis
Allergic interstitial nephritis
Glomerulonephritis or vasculitis
Multiple myeloma
Myoglobinuria or hemoglobinuria
Treat for the underlying cause
Stop the causative drug and administer glucocorticoids
Perform renal biopsy
Serum and urine immunoelectrophoresis
Administer fluids, mannitol; perform urine alkalinization
Supportive management
Resolution of renal insufficiency
Unresponsive volume overload, acidosis, or hyperkalemia
Signs and symptoms of uremia [blood urea nitrogen >100 mg per dL (35.70 mmol/L)]
Perform renal replacement therapy (dialysis)

- **Systemic complications of ARF: Infections** and **gastrointestinal bleeding** are two important complications.
  - **Infectious complications** [very high (80%)] includes pulmonary, urinary, and wound infections (in post-traumatic and postoperative patients). Infections should be treated promptly by **appropriate antibiotics**.
  - **Gastrointestinal bleeding** (in 40% of patients) may prove fatal and treated by proton pump inhibitors and gastroprotective agents. Qualitative platelet dysfunction, which results in a hemorrhagic diathesis.

- **Use of drugs: Great care is necessary** in the use of drugs and nephrotoxic drugs should be avoided.

Treatment of the underlying cause of the AKI:

- **Identify the cause** (by simple initial investigations such as ultrasound or may require additional investigations, including renal biopsy) and **correct it, if possible.**

Specific therapy:

- **No specific treatment** for ATN, other than restoring renal perfusion.
- **Intrinsic kidney disease may require specific therapy** (e.g., immunosuppressive drugs such as corticosteroids and cyclophosphamide in some causes of **rapidly progressive glomerulonephritis**).
- **"Postrenal" obstruction** requires **urgent relief of obstruction**. Once the blood chemistry returns to normal, the underlying cause should be treated whenever possible.
- **Drug-induced** acute tubule-interstitial nephritis usually recovers after stopping the offending drug, but sometimes, short course of steroids may be helpful.
- **If conservative measures fail, dialysis and hemofiltration** may be necessary. These techniques purify blood and/or remove excess fluid. Main indications of dialysis and hemofiltration in ARF are listed in **Table 10.16. Table 10.17** lists the preventive strategies for conditions with high risk of acute kidney injury.

Q. Write short note on indications for dialysis in acute renal failure.

TABLE 10.16: Indications of dialysis or hemofiltration in acute renal failure (ARF).

1. Fluid overload refractory to diuretics and refractory pulmonary edema 2. Severe metabolic acidosis (pH < 7.1) 3. Resistant hyperkalemia 4. Complications of uremia (e.g., pericarditis, encephalopathy, neuropathy) 5. Increased plasma urea (>180 mg/dL) and creatinine (>6.8 mg/dL) 6. ESRD (end-stage renal disease)	7. Severe biochemical derangement in the absence of symptoms (especially in an oliguric and hypercatabolic patients) 8. Removal of drugs causing the acute renal failure (e.g., gentamicin, lithium, severe aspirin overdose) 9. Severe hyperphosphatemia (defined as >12 mg/dL) 10. Tumor lysis syndrome 11. Anuria for >12 hours

Indications for urgent renal replacement therapy:

- Pulmonary edema
- Hyperkalemia:
  - >6.5 mEq/L
  - Signs and symptoms of hyperkalemia such as cardiac conduction defects, muscle weakness
  - >5.5 mEq/L with ongoing muscle breakdown (rhabdomyolysis) or ongoing potassium absorption [gastrointestinal (GI) bleed]
- Signs of uremia (pericarditis, seizures, severe declining mental status)
- Severe metabolic acidosis (pH < 7.1), unless it is easily reversible such as diabetic ketoacidosis
- Acute poisonings

TABLE 10.17: Preventive strategies for conditions with high risk of acute kidney injury.

Risk factors	***Preventive strategies***
Cancer chemotherapy (risk of tumor lysis syndrome)	Hydration and allopurinol administration a few days before chemotherapy initiation
Exposure to nephrotoxic medications	➢ Avoid nephrotoxic medications if possible. Use appropriate dosing, intervals, and duration of therapy
Exposure to radiographic contrast agents	➢ Avoid use of intravenous contrast media when risks outweigh benefits ➢ If use of contrast media is essential, use iso-osmolar or low-osmolar contrast agent with lowest volume possible ➢ Use of N-acetylcysteine may be considered
Hemodynamic instability	➢ Optimal fluid resuscitation, a mean arterial pressure goal of >65 mm Hg is widely used; isotonic solutions (e.g., normal saline) ➢ Vasopressors are recommended for persistent hypotension (mean arterial pressure <65 mm Hg) despite fluid resuscitation ➢ Dopamine is not recommended
Hepatic failure	➢ Avoid hypotension and gastrointestinal bleeding ➢ Early recognition and treatment of spontaneous bacterial peritonitis; use albumin, 1.5 g/kg at diagnosis and 1 g/kg at 48 hours ➢ Albumin infusion during large volume paracentesis ➢ Avoid nephrotoxic medications
Rhabdomyolysis	➢ Maintain adequate hydration ➢ Alkalinization of the urine with intravenous sodium bicarbonate in select patients
Undergoing surgery	➢ Adequate volume resuscitation/prevention of hypotension, sepsis, optimizing cardiac function ➢ Consider holding renin-angiotensin system antagonists preoperatively

Cause of death: Most common causes of death in ARF (in the absence of dialysis) are hyperkalemia and pulmonary edema, followed by infection and uremia.

GLOMERULAR DISEASES

Q. PA28.5 Define and classify glomerular diseases. Enumerate and describe the etiology, pathogenesis, mechanisms of glomerular injury, pathology, distinguishing features and clinical manifestations of glomerulonephritis.

The syndromes of glomerular disease are mentioned in **Box 10.6.**

Box 10.6: Syndromes of glomerular disease.

- Acute nephritic syndrome
- Rapidly progressive glomerulonephritis
- Nephrotic syndrome
- Chronic nephritis
- Asymptomatic urinary abnormalities (hematuria, proteinuria or both)

GLOMERULONEPHRITIS

- Glomerulonephritis: Inflammation of glomeruli **and most are** due to an **immunologically mediated injury**.
- **Glomerulopathy:** Glomerular diseases **without apparent inflammation.** There is an overlap between these terms.

Causes of Glomerulonephritis (Box 10.7)

Box 10.7: Causes of glomerular diseases.

Primary glomerulonephritis/glomerulopathies
- Acute proliferative glomerulonephritis: Postinfectious, others
- Rapidly progressive (crescentic) glomerulonephritis
- Minimal-change disease
- Membranous glomerulopathy
- Membranoproliferative glomerulonephritis
- Focal segmental glomerulosclerosis
- Immunoglobulin A nephropathy
- Chronic glomerulonephritis

Systemic diseases with glomerular involvement
- Systemic immunological diseases: Systemic lupus erythematosus
- Metabolic diseases: Diabetes mellitus
- Vasculitis: Microscopic polyarteritis/polyangiitis, Wegener granulomatosis, Henoch–Schönlein purpura
- Amyloidosis
- Goodpasture syndrome
- Bacterial endocarditis

Hereditary disorders
- Alport syndrome
- Thin basement membrane disease
- Fabry disease

Pathogenesis

Main mechanism is antibody-mediated glomerular injury.

1. **Immune complex-mediated:**
   - Glomerular injury develops due to deposition of **circulating antigen-antibody complexes** (immune complexes) in the glomerulus. There is trapping of circulating antigen-antibody complexes within glomeruli which results in glomerular damage. The antibodies are not against any of glomerular constituents, and the immune complexes localize within the glomeruli.
   - The antigen may be exogenous [e.g., bacteria as in poststreptococcal glomerulonephritis (PSGN) or endogenous (e.g., antibodies to host DNA in patients with systemic lupus erythematosus (SLE)].

2. **Anti-GBM antibody-induced glomerulonephritis:** It develops due to injury by antibodies to the insoluble fixed (intrinsic) glomerular basement antigens. Anti-GBM antibody-induced GN is responsible for <5% of cases of GN. This type of injury is caused due to antibodies which are produced against intrinsic fixed antigens (that are normal components) of the GBM proper.

Terms used in glomerular diseases

- **Focal:** Some glomeruli, but not all show the lesion.
- **Diffuse (global):** Most of the glomeruli (>75%) show the lesion.
- **Segmental:** Only a part of the glomerulus is affected (most focal lesions are also segmental, e.g., focal segmental glomerulosclerosis).
- **Proliferative:** Increase in cell numbers due to hyperplasia of one or more of the resident glomerular cells with or without inflammation.
- **Membranous:** Capillary wall thickening due to deposition of immune deposits or alterations in basement membrane.
- **Crescent formation:** Proliferation of parietal epithelial cell with mononuclear cell infiltration in Bowman's space.

Box 10.8: Characteristics of acute nephritic syndrome.

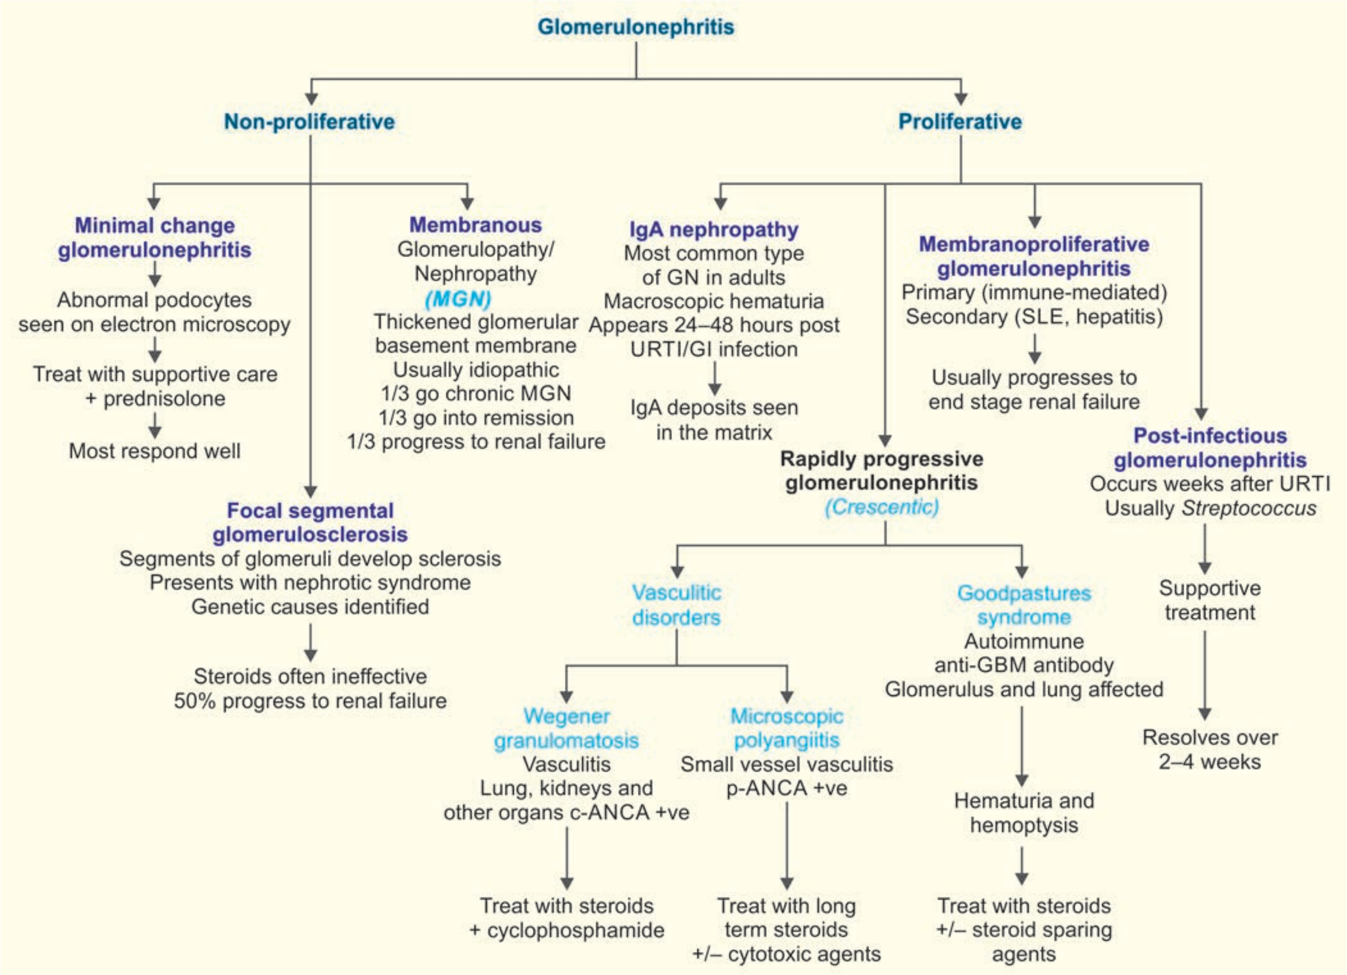
- **Hematuria** (gross or microscopic)
- **Red cell casts in the urine**
- **Azotemia** (temporary)
- **Temporary oliguria** (due to decreased glomerular filtration rate)
- **Hypertension**
- Proteinuria*
- **Edema*** (periorbital, leg or sacral)

*Not as severe as in nephrotic syndrome.

Characteristics of acute nephritic syndrome are presented in **Box 10.8.**

Spectrum of glomerular diseases are presented in **Flowchart 10.4** and various causes of proliferative and nonproliferative GN are shown in **Figure 10.8**.

FLOWCHART 10.4: Spectrum of glomerular diseases.



Glomerulonephritis
Non-proliferative
Proliferative
Minimal change glomerulonephritis
Abnormal podocytes seen on electron microscopy
Treat with supportive care + prednisolone
Most respond well
Membranous Glomerulopathy/ Nephropathy (MGN)
Thickened glomerular basement membrane
Usually idiopathic
1/3 go chronic MGN
1/3 go into remission
1/3 progress to renal failure
Focal segmental glomerulosclerosis
Segments of glomeruli develop sclerosis
Presents with nephrotic syndrome
Genetic causes identified
Steroids often ineffective
50% progress to renal failure
IgA nephropathy
Most common type of GN in adults
Macroscopic hematuria
Appears 24–48 hours post URTI/GI infection
IgA deposits seen in the matrix
Membranoproliferative glomerulonephritis
Primary (immune-mediated)
Secondary (SLE, hepatitis)
Usually progresses to end stage renal failure
Rapidly progressive glomerulonephritis (Crescentic)
Post-infectious glomerulonephritis
Occurs weeks after URTI
Usually Streptococcus
Supportive treatment
Resolves over 2–4 weeks
Vasculitic disorders
Goodpastures syndrome
Autoimmune
anti-GBM antibody

Membranous nephropathy
Amyloidosis
Post-streptococcal glomerulonephritis
Nephritic
Mechanism
• Inflammation
• Reactive cell proliferation
• Breaks in GBM
• Crescent formation
Hematuria
Proteinuria

FIG. 10.8: Various causes of proliferative and nonproliferative glomerulonephritis.
(FSGS: Focal segmental glomerulosclerosis; IgA: Immunoglobulin A; MPGN: Membranoproliferative glomerulonephritis; SLE: Systemic lupus erythematosus; GBM: Glomerular basement membrane)

Acute Proliferative Glomerulonephritis

These are immune complexes mediated diseases. The inciting antigen may be:

- **Exogenous,** e.g., postinfectious GN which commonly follows streptococcal infection, but may also associated with other infections
- **Endogenous,** e.g., nephritis of SLE
- It is characterized histologically by cellular proliferation (mesangial and endothelial) associated with infiltration by leukocytes (neutrophils, macrophages).

Poststreptococcal (Postinfectious) Glomerulonephritis

Q. Write short essay/note on acute glomerulonephritis or acute nephritic syndrome and its causes and clinical features.

Q. PE21.2 Enumerate the etiopathogenesis, clinical features, complications and management of acute poststreptococcal glomerular nephritis in children.

Poststreptococcal glomerulonephritis is specific subtype of postinfectious glomerulonephritis. It is common in developing countries and one of the common causes of **acute nephritic syndrome.**

Age group: Most frequently seen in **children between 6 and 10 years** of age, but may develop in adults.

Etiology and Pathogenesis

- The **primary streptococcal infection** usually involves the **pharynx** (pharyngitis) or the **skin** (impetigo/pyoderma). Skin infections are usually associated with overcrowding and poor hygiene.
- Only certain strains of **group A β-hemolytic streptococci** are nephritogenic. More than 90% are due to **types 12, 4, and 1**.
- Commonly associated with poor personal hygiene, overcrowding and skin diseases such as scabies.
- It is an immunologically mediated disease **and** evidences to support **this are:**
  - **Latent period:** It manifests usually after a latent period of **1–4 weeks** following primary streptococcal infection. Cutaneous infections are associated with longer latent period. This latent period is compatible with the time required for the production of antibodies and the immune complex formation.
  - **Antibodies against streptococcal antigens:** Majority of patients show increased titers of antibodies against one or more streptococcal antigens. These antibodies include: antistreptolysin O (ASO), antideoxyribonuclease B (anti-DNase B), antistrepokinase, antihyaluronidase, and antinicotinyl adenine dinucleotidase.
  - **Hypocomplementemia:** Immune complexes activate and utilize complement components and more than 90% of patients reveal decreased complement (C3 and C4) levels in the blood (hypocomplementemia).
  - **Immune complex deposits:** Electron microscopy shows glomeruli with electron dense deposits of immune complexes. Immunofluorescence shows granular fluorescence to the immune deposits.

- **Streptococcal antigens in the glomeruli:** Many *cationic antigens* unique to nephritogenic strains of streptococci can be demonstrated in the glomeruli. Example, nephritis-associated streptococcal plasmin receptor (NAPlr), streptococcal pyrogenic exotoxin B (SpeB) and its zymogen precursor (zSpeB).

Clinical Features

- Onset is often abrupt.
- Usually the affected child suddenly develops **malaise, fever, nausea, oliguria, and hematuria** (characteristically, urine appears **smoky or** red or **cola-colored urine**) 1–4 weeks after recovery from a sore throat.
- **Periorbital edema** (causes puffiness of face), and **mild to moderate hypertension** is usually observed. Edema initially appears in areas of low tissue pressure (periorbital areas), followed by involvement of dependent portions of the body, and may be associated with ascites and/or pleural effusion.
- In adults clinical features are atypical. They may present with the sudden appearance of **hypertension or edema, and elevation of BUN.**

Investigations (Table 10.18)

TABLE 10.18: Various laboratory findings in acute poststreptococcal glomerulonephritis (PSGN).

Blood findings	*Urinary findings*
➢ Raised **antistreptococcal antibody,** titers, e.g., antistreptolysin O (ASO) titer ➢ Significant **reduction in serum concentration of complement** (C3) components ➢ Urea and creatinine: May be elevated and indicates renal impairment	➢ **Oliguria** ➢ **Mild (variable degree) proteinuria** (usually less than 1 g/day) ➢ **Hematuria** (**smoky or cola-colored urine**) ➢ Urine microscopy: – Red cells (particularly dysmorphic, i.e., distorted and fragmented red cells) – Red cell casts
Renal biopsy: Diffuse acute inflammation in the glomerulus with neutrophils and deposition of immunoglobulin G (IgG) and complement. Electron microscopy shows electron-dense deposits in the subepithelial aspects of the capillary walls.	

Management/Treatment

- **Supportive treatment during acute PSGN:** These include **rest, salt restriction, diuretics and antihypertensives**.
- **Dialysis is necessary when there is severe oliguria, fluid overload, and hyperkalemia.**
- Steroids and cytotoxic drugs are of no value. However, if recovery is slow or if RPGN develops, corticosteroids (methylprednisolone) may be of some help.

Complications

Q. List the complications of acute poststreptococcal glomerulonephritis/nephritic syndrome.

(1) Rapidly progressive glomerulonephritis, (2) pulmonary edema, (3) hypertensive encephalopathy, and (4) renal failure.

Prognosis

Majority of patients with the epidemic form of PSGN have an **excellent prognosis.**

- **Children: Prognosis is good** and more than 95% totally recover. Minority may develop a RPGN.
- **Adults: Less benign**. They may recover promptly or develop RPGN or progress to chronic glomerulonephritis (hypertension and/or renal impairment).

Prevention: Pharyngitis caused by streptococci should be treated promptly by antibiotics which protects against development of GN.

Rapidly Progressive Glomerulonephritis/Crescentic Glomerulonephritis

Q. Write short essay/note on the causes, clinical features, investigations, and treatment of rapidly progressive glomerulonephritis.

Q. Write short essay/note on crescentic glomerulonephritis.

Definition: Rapidly progressive glomerulonephritis is a **syndrome**, characterized by **rapid and progressive loss of renal function** (usually a 50% reduction in the GFR within 3 months) associated with **severe oliguria and signs of nephritic syndrome**. If not treated death occurs due to renal failure within weeks to months. Histologically, it is characterized by **extensive crescents** (usually >50%).

Crescent

Crescents are formed by the **proliferation of the parietal epithelial cells** lining Bowman capsule along with the **infiltration of monocytes and macrophages**.

Classification

Rapidly progressive glomerulonephritis classified into three types based on immunological findings **(Table 10.19)**. Each type may be idiopathic or associated with a known disorder.

Clinical Features (Table 10.20)

Investigations

- **Blood**
  - Leukocytosis and anemia
  - **Blood urea and serum creatinine** levels: Usually **raised.**

TABLE 10.19: Classification of rapidly progressive glomerulonephritis (GN).

Type of RPGN
Type I (anti-GBM antibody) (linear deposits of IgG and C3 on IF)
➢ Goodpasture syndrome
Type II (immune complex) (granular deposits of immune complex)
➢ Idiopathic immune complex-mediated RPGN
➢ IgA nephropathy
➢ Membranous glomerulopathy
➢ Mesangiocapillary GN
➢ Associated with secondary GN
➢ Post-infectious glomerulonephritis (poststreptococcal GN)
➢ Lupus nephritis
➢ Henoch–Schönlein purpura
➢ Mixed cryoglobulinemia
Type III (pauci-immune) (no deposits on IF)
➢ Idiopathic
➢ Wegener granulomatosis
➢ ANCA-associated
➢ Microscopic polyangiitis
➢ Renal-limited necrotizing crescentic glomerulonephritis
➢ Churg–Strauss syndrome

(ANCA: Antineutrophil cytoplasmic antibodies; GBM: Glomerular basement membrane; IF: Immunofluorescent; IgA: Immunoglobulin A; IgG: Immunoglobulin G; RPGN: Rapidly progressive glomerulonephritis)

TABLE 10.20: Usual clinical features of RPGN.

➢ **Hematuria with RBC casts** in the urine	➢ **Variable hypertension** and edema
➢ **Moderate proteinuria**	➢ **Oliguria and uremia**
In **Goodpasture syndrome** patient may present with recurrent hemoptysis or life-threatening pulmonary hemorrhage	

(RPGN: Rapidly progressive glomerulonephritis)

TABLE 10.21: Complement levels in nephritic syndrome.

Low complement	*Normal complement*
➢ Postinfectious glomerulonephritis	➢ IgA nephropathy
➢ Mesangiocapillary glomerulonephritis	➢ Idiopathic crescentic glomerulonephritis
➢ Systemic lupus erythematosus	➢ Anti-GBM disease
➢ Infective endocarditis	➢ Vasculitides: Henoch–Schönlein purpura, Wegener's granulomatosis, microscopic polyangiitis
➢ Essential mixed cryoglobulinemia	

(IgA: Immunoglobulin A)

- **Urinalysis**
  - **Moderate proteinuria** (1–4 g/day)
  - Microscopic hematuria
  - **RBC and WBC casts.**
- **Others**
  - **Complement levels** (C3 and C4): **May be decreased** in immune-complex mediated RPGN.
  - **Circulating anti-GBM antibodies:** In Goodpasture syndrome.
  - Antineutrophil cytoplasmic antibody: In pauci-immune RPGN.
  - Serum cryoglobulin levels: May be raised in cryoglobulinemia.
- **Abdominal ultrasound:** Normal sized kidneys.
- **Chest X-ray:** Patients with Goodpasture syndrome and vasculitides may show **diffuse opacities** if associated with pulmonary hemorrhage.
- **Renal biopsy:** Shows **crescents**.

Treatment

It depends on the factors involved in the pathogenesis.

- **Supportive therapy:**
  - **Control of infection**
  - **Control of volume status** (dialysis may be needed)
- **Specific therapy:**
  - **Plasma exchange** to remove circulating antibodies and in patients presenting with life-threatening pulmonary hemorrhage.
  - **Steroids methylprednisolone—500–1,000 mg/day for 3 days to suppress inflammation** from antibody already deposited in the tissue.
  - **Immunosuppressive therapy** (e.g., cyclophosphamide, azathioprine, mycophenolate) such as cyclophosphamide to suppress further antibody synthesis.
  - **Infliximab and rituximab.**

Complement Levels in Nephritic Syndrome (Table 10.21)

Algorithm of approach to the patient presenting with acute glomerulonephritis/nephritic syndrome is presented in **Flowchart 10.5**.

NEPHROTIC SYNDROME

Q. Discuss the etiology, pathogenesis, clinical features, diagnosis, and management of nephrotic syndrome.

Q. Define nephrotic syndrome. Discuss the differential diagnosis in a 30-year-old male presenting with anasarca.

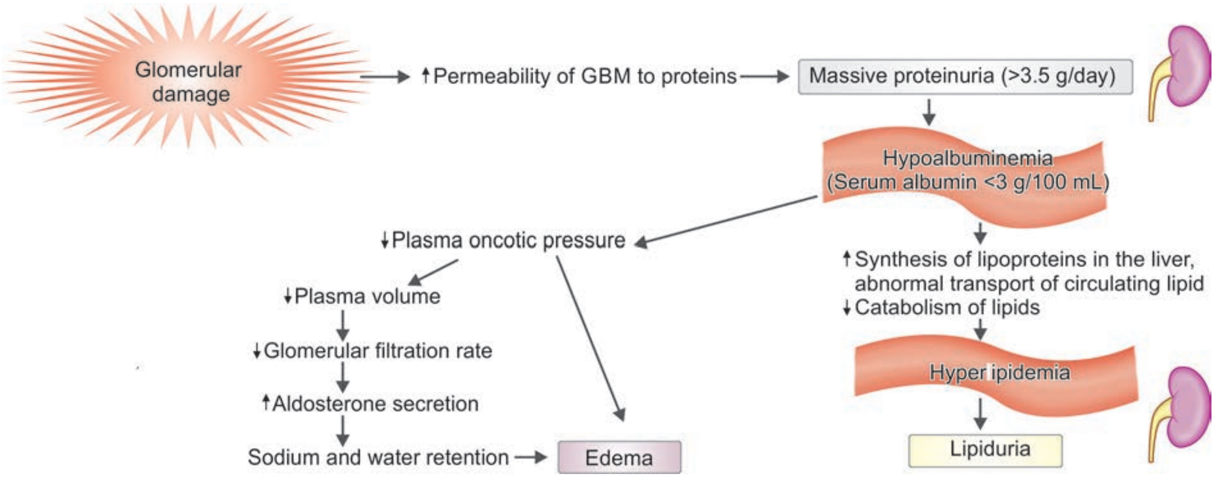
Features of nephrotic syndrome are mentioned in **Box 10.9**.

Pathophysiology (Fig. 10.9)

- **Massive proteinuria** is characterized by **daily loss of 3.5 g or more** of **protein** (less in children) in the **urine**.
    - Normally, the glomerular capillary wall acts as a size and charge dependent barrier for the plasma filtrate.
    - Proteinuria in nephrotic syndrome is due to **increased permeability of glomerular capillary wall to plasma proteins.** This increased permeability is due to glomerular inflammation, change in the surface electrical charge, and an alteration in the pore size.
    - The **major proportion of protein** lost in the urine is **albumin**, and rarely globulins. Consequences of protein loss are listed in **Table 10.22**.

Box 10.9: Characteristics of nephrotic syndrome.

- Massive/heavy proteinuria (>3.5 g of protein/24 hours)
- Hypoalbuminemia
- Generalized edema
- Hyperlipidemia and lipiduria



Glomerular damage
↑Permeability of GBM to proteins
Massive proteinuria (>3.5 g/day)
Hypoalbuminemia (Serum albumin <3 g/100 mL)
↓Plasma oncotic pressure
↓Plasma volume
↓Glomerular filtration rate
↑Aldosterone secretion
Sodium and water retention
Edema
↑Synthesis of lipoproteins in the liver, abnormal transport of circulating lipid
↓Catabolism of lipids
Hyperlipidemia
Lipiduria

FIG. 10.9: Various characteristic features of nephrotic syndrome and its mechanism.
(GBM: Glomerular basement membrane)

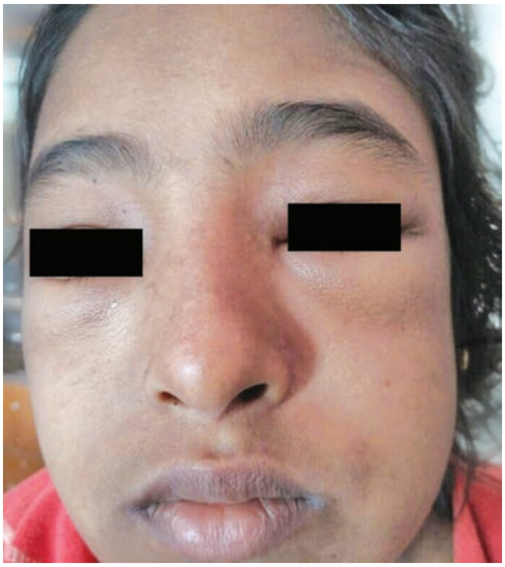


FIG. 10.10: Facial and periorbital puffiness in nephrotic syndrome.

TABLE 10.22: Consequences of protein loss/complications of nephrotic syndrome.

Nature of protein loss	***Consequences***
Hypoalbuminemia	Edema and may also produce pleural effusion and ascites. Subungual edema may manifest as parallel white lines in the fingernail beds Increased susceptibility to infections
Urinary losses of plasma proteins such as thyroxine-binding globulin	Abnormalities in thyroid function tests, hypothyroidism
Deficiency of antithrombin III (due to urine loss)	Hypercoagulable state (consequences include DVT, pulmonary embolism, myocardial infarction, and stroke) and renal vein thrombosis
Loss of globulins in urine	Severe IgG deficiency leading to infections such as spontaneous bacterial peritonitis
Loss of cholecalciferol-binding protein	Vitamin D deficiency state
Loss of transferrin	Microcytic hypochromic anemia
Loss of metal-binding proteins	Metal deficiency, e.g., zinc, copper
Loss of drug-binding proteins	Altered drug pharmacokinetics

(DVT: Deep venous thrombosis; IgG: Immunoglobulin G)

- Hypoalbuminemia
  - Massive proteinuria decreases the serum albumin levels (hypoalbuminemia).
  - **Hypoalbuminemia decreases the colloid osmotic pressure** of the blood resulting in a disturbance in the Starling forces acting across peripheral capillaries.
  - The **hypovolemia also triggers the RAA** system. This causes **increased reabsorption of sodium and water** by the kidney, resulting in edema.
    - Generalized edema
      - Soft and pitting
  - **Most marked in the periorbital regions** (**Fig. 10.10**) and dependent portions of the body.
  - Associated with pleural effusions and ascites.
- Hyperlipidemia and lipiduria
  - ***Hyperlipidemia:*** Most patients with nephrotic syndrome have raised blood levels of cholesterol, triglyceride, very-low-density lipoprotein, low-density lipoprotein, Lp(a) lipoprotein, and apoprotein. It **increases risk of atherosclerosis** and **cardiovascular disease.**
  - **Causes** of hyperlipidemia: **Increased synthesis** of lipoproteins in the liver due to low plasma colloid oncotic pressure. **Abnormal transport** of circulating lipid. **Decreased catabolism** of lipids.

- ***Lipiduria:*** Hyperlipidemia is followed by leakage of lipoproteins across the glomerular capillary wall → leaked lipoprotein is reabsorbed by tubular epithelial cells then shed along with the degenerated cells → appears in urine either as free fat or as oval fat bodies.

Causes of Nephrotic Syndrome (Box 10.10 and Fig. 10.11)

Q. **Write short essay on causes/etiology, pathogenesis, clinical features, investigations, and treatment of minimal change disease.**

Box 10.10: Causes of nephrotic syndrome.

A. Primary (idiopathic) glomerular disease
- Membranous glomerulopathy (~30% in adults)
- Minimal-change disease (~65% in children)
- Focal segmental glomerulosclerosis (FSGS ~35% in adults)
- Membranoproliferative glomerulonephritis
- Immunoglobulin A (IgA) nephropathy
- Mesangial proliferative

B. Infection-related
- Malaria (quartan malaria)
- Infective endocarditis
- Hepatitis B and C
- HIV
- Syphilis

C. Systemic diseases
- Diabetes mellitus
- Amyloidosis
- Systemic lupus erythematosus
- Polyarteritis nodosa
- Wegener's granulomatosis

D. Drug and toxins: Penicillamine, gold, street heroin, captopril

E. Malignancy
- Carcinoma
- Melanoma
- Hodgkin's disease, chronic lymphatic leukemia

F. Others: Bee-sting allergy, hereditary nephritis

- **Minimal change disease (MCD)**
  - Minimal change disease is named so because the **glomerular changes** are **absent or minimal and glomeruli appear normal under light microscopy.** But under electron microscopy, it shows **diffuse effacement (loss) of foot processes** of visceral epithelial cells (podocytes).
  - **Minimal change disease is the** major cause of nephrotic syndrome in children (80%), but it is less common in adults (20%).
  - **Age:** Peak incidence between 2 and 6 years of age.

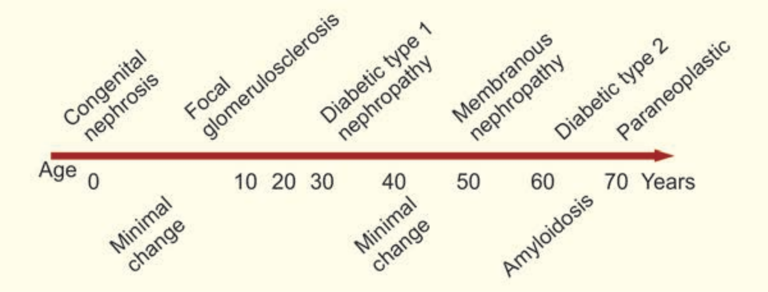

FIG. 10.11: Etiology of nephrotic syndrome by age.

- **Focal and segmental glomerulosclerosis (FSGS)**
  - FSGS is characterized by the **sclerosis** that **involves only part of the capillary tuft** (i.e., segmental) **of some glomeruli** (i.e., focal).
  - Accounts for about **one-third of cases of nephrotic syndrome in adults**.
  - Usually manifest as nephrotic syndrome or heavy proteinuria, hypertension, renal insufficiency, and occasionally hematuria.
  - **Causes (Box 10.11)**

Box 10.11: Causes of focal and segmental glomerulosclerosis.

Primary (idiopathic)

Secondary
- Viruses: HIV infection
- Drugs: Heroin addiction
- Sickle-cell disease
- Massive obesity
- Congenital (e.g., unilateral agenesis) and acquired (e.g., reflux nephropathy) reductions in renal mass
- ***Hereditary forms:*** Inherited mutations in genes that encode podocyte proteins, e.g., podocin, α-actinin 4

- **Membranous nephropathy**
  - Characterized by **uniform diffuse thickening of the glomerular capillary wall.** This is due to the accumulation of **electron-dense deposits along the subepithelial side** of the glomerular basement membrane.
  - **Common cause (~30%) of the nephrotic syndrome in adults.**
  - **Gender and age:** Male predominance and high incidence between 30 to 50 years of age.

  - **Causes (Box 10.12)**
  - About 75% of patients present with nephrotic-range proteinuria and 50% present with microscopic hematuria.

Box 10.12: Causes of membranous nephropathy.

Primary/idiopathic: No identifiable cause in about 85% of patients

Secondary (20–30% cases): In association with:

- **Therapeutic drugs:** Penicillamine, captopril, nonsteroidal anti-inflammatory drugs (NSAIDs), gold
- **Malignant neoplasms**, e.g., carcinomas of the lung and colon, lymphomas and melanoma
- **Autoimmune disease**, e.g., systemic lupus erythematosus (SLE), thyroiditis
- **Infections:** Chronic hepatitis B, hepatitis C, quartan malaria, syphilis, schistosomiasis

Investigations in Nephrotic Syndrome

Q. Write a short note on urinary findings in nephrotic syndrome.

- **Urine examination**
  - **Proteinuria:** Twenty-four hour urinary protein estimation.
  - **Microscopy:** Red cells and red cell casts and waxy casts may be present. However, in minimal change disease, RBCs and red cell casts are not seen. Shows lipiduria
- **Serum albumin: Reduced**
- **Serum cholesterol: Raised**
- **Renal biopsy: May be necessary** for histological diagnosis.
- **Other investigations:** Depending on the suspected secondary causes appropriate investigations are to be performed.

Management

A. General measures

Measures to reduce proteinuria: These measures are necessary if immunosuppressive drugs and other specific measures against the underlying cause do not benefit.

- **Angiotensin-converting enzyme inhibitors and/or angiotensin II receptor antagonists:** They **reduce proteinuria** in all types of GN and also slow **the rate of progression of renal failure** by lowering glomerular capillary filtration pressure. Blood pressure and renal function should be monitored regularly during their administration.

Measures to control complications

- **Treatment of edema:**
  - Initially, it is treated by **dietary salt (sodium) restriction, rest and a thiazide diuretic** (e.g., chlorthalidone, bendroflumethiazide). The weight loss should not be more than 1 kg/day. Aggressive diuretic therapy may precipitate ARF due to reduction in intravascular volume.
  - **If not responsive, furosemide 40–120 mg daily** with the **addition of amiloride** (5 mg daily), and serum potassium concentration should be monitored.
  - **Gut mucosal edema** in nephrotic syndrome may **cause malabsorption of diuretics** (as well as other drugs). Thus, if there is **resistance to oral diuretic treatment, parenteral administration is required.**
  - In diuretic-resistant patients and those with oliguria and uremia in the absence of severe glomerular damage (e.g., in minimal-change nephropathy) edema may be treated by **infusion of salt-poor albumin as a temporary measure combined with diuretic therapy**. However, most of infused albumin will be excreted by the kidneys within 1–2 days.
  - **Dietary proteins:** It is advisable to **take normal protein** and should be about 0.8–1.0 g/kg. A high-protein diet(Approximately 80–90 g protein daily) increases proteinuria and may be harmful in the long-term. However, malnutrition should be prevented.
- **Hypercoagulable state:** Develops due to loss of coagulation factors (e.g., antithrombin) in the urine and an increase in production of fibrinogen by liver. It predisposes to venous thrombosis and thromboembolism. Therefore, avoid prolonged bed rest. Long-term prophylactic anticoagulant therapy is desirable and it is indicated in patients who have already developed deep venous thrombosis or arterial thrombosis.
- **Lipid abnormalities:** They **increase in the risk of myocardial infarction or peripheral vascular disease.** Hypercholesterolemia is treated with an **HMG-CoA reductase inhibitor and dietary restrictions of lipids.**
- **Vitamin D supplementation:** To be given if there is biochemical evidence of vitamin D deficiency.
- **Sepsis:** It is a **major cause of death** in nephrotic syndrome. The increased susceptibility to infection is partly due to loss of immunoglobulin in the urine. They are particularly **susceptible to pneumococcal infections** and pneumococcal vaccine should be given to these patients. Early detection and aggressive treatment of infections should be done. Vaccinations prophylactically is advisable.

B. Treatment of underlying cause

Minimal change disease

- **In children:**
  - **Initial treatment** by **high-dose corticosteroid** therapy with prednisolone 60 mg/m^2 daily (up to a maximum of 80 mg/day) for a maximum of 4–6 weeks.
  - Followed by alternate day prednisolone at a dose of 40 mg/m^2 (1 mg/kg in adults) for further 4–6 weeks.

  - **More than 95% of children respond** to the above therapy. Children who respond within the first 4 weeks of corticosteroid therapy are termed "steroid responsive." Those who relapse on withdrawal of corticosteroid therapy are termed "steroid dependent."
  - **Relapse:**
    - One-third of patients relapse on steroid withdrawal, and remission is once more induced with **steroid therapy**.
    - In patients who have frequent relapses or develop unacceptable corticosteroid side effects, long-term remission can be achieved by a course of **cyclophosphamide** 1.5–2.0 mg/kg daily is given for 8–12 weeks **with concomitant prednisolone** 7.5–15 mg/day. Steroid unresponsive patients may also benefit by cyclophosphamide. Not more than two courses of cyclophosphamide should be given because of the risk of side-effects (e.g., azoospermia).
    - An alternative to cyclophosphamide is **ciclosporin** 3–5 mg/kg/day (ciclosporin is potentially nephrotoxic).
- **Adults: Response rates are significantly lower** and response may occur late (12 weeks with daily steroid therapy and 12 weeks of maintenance with alternate-day therapy).
- **Prognosis: Excellent,** although it may show remission and relapses.

Focal and segmental glomerulosclerosis

- **Steroids:** It is **beneficial in only 20–30% patients** and usually prednisolone is given in the dose of 0.5–2 mg/kg/day.
- **Cyclosporine** may be effective in reducing or stopping urinary protein excretion.
- **Cyclophosphamide, chlorambucil or azathioprine** may be used **as second-line therapy in adults.**
- About **50% progress to end-stage renal failure**.

Membranous glomerulonephritis

- **Oral high-dose corticosteroids are not useful for** producing either a sustained remission of nephrotic syndrome or preserving renal function.
- **Alkylating agents: Cyclophosphamide and chlorambucil** are effective. However, because of long-term toxicity, these drugs should be reserved for patients who have severe or prolonged nephrosis (i.e., proteinuria >6 g/day for >6 months), renal insufficiency, and hypertension. **Cyclophosphamide, cyclosporine and chlorambucil** in combination with steroids may be helpful.
- **Anti-B lymphocyte therapy is more effective** against T lymphocytes than broad-spectrum immunosuppressive agents. Anti-CD20 antibodies (rituximab, which ablates B lymphocytes) improve renal function, reduce proteinuria and increase the serum albumin.
- **Prognosis:** Spontaneous remission may occur in 40%, 3–40% may develop repeated remissions and relapses and 10–20% patients may develop progressive renal failure.

Immunoglobulin A Nephropathy (Berger's Disease)

Q. Write short essay/note on IgA nephropathy.

- Characterized by **focal and segmental proliferative GN** with **predominant IgA deposition in the glomerular mesangium**.
- **Clinical features:**
  - Occurs in **children and young males**.
  - **Presents with** asymptomatic/painless microscopic hematuria or recurrent macroscopic hematuria **generally within** 1–2 days after an upper respiratory or gastrointestinal viral infection (synpharyngitic nephritis).
  - Proteinuria occurs and in 5% it can be in the nephrotic range.
  - Occasionally, it may present as ARF or nephritic syndrome.
- **Diagnosis by renal biopsy:** Immunofluorescence microscopy shows prominent **IgA deposits** in the mesangial regions.
- **Prognosis:**
  - **Usually good**, especially in patients with normal blood pressure, normal renal function, and absence of proteinuria at presentation.
  - Complete remission uncommon.
  - **Risk of development of end-stage renal failure** in about 25% of patients with proteinuria of more than 1 g/day, elevated serum creatinine, hypertension, ACE gene polymorphism and presence of tubule-interstitial fibrosis on renal biopsy.

Management

- **Steroids:** Used for patients with proteinuria of 1–3 g/day, mild glomerular changes only, and preserved renal function. They reduce proteinuria and stabilize renal function. Oral budesonide has been tried.
- **Use of immunosuppressive therapy is controversial**.
- **Combination therapy:** In patients with progressive disease (creatinine clearance <70 mL/min), **prednisolone with cyclophosphamide** can be used for 3 months followed by maintenance with prednisolone and azathioprine.
- **Tonsillectomy: May reduce proteinuria and hematuria** in patients with recurrent tonsillitis.
- **Combination of ACE inhibitor and angiotensin II receptor antagonist:** Can be given to all patients, with or without hypertension and proteinuria. This combination therapy reduces proteinuria and preserves renal function.

Hereditary Nephritis or Alport's Syndrome

- Most common familial nephropathies, characterized by familial occurrence of **progressive hematuria, nephritis, and sensorineural loss of hearing.**
- Common in females. Male patients develop severe renal disease with progressive renal failure occurring before the fourth decade. Most females have a normal life-span.
- **Pathology:** Electron microscopy—shows irregular thickening of GBM, splitting and splintering of the lamina densa and small, round, electron-dense granulations are present within the lucent zones. GBM lesions are the hallmark but not specific of Alport's syndrome.
- **Clinical presentation**
  - Major presentation: Macroscopic or microscopic hematuria and may be observed at birth.
  - Other presenting features: Proteinuria, edema, hypertension, renal failure, and deafness.
    - Microscopic or recurrent episodes of macroscopic hematuria following upper respiratory infection (or physical exertion) may resemble postinfective glomerulonephritis.
    - Incidental leukocyturia and pyuria may lead to erroneous diagnosis of UTI.
    - Nephrotic syndrome can occur with increasing proteinuria. Hypertension develops with progressive renal insufficiency.
    - Deafness is more frequent in males and progression of hearing loss usually indicates poor prognosis.
    - Ocular changes include anterior lenticonus (most common) and associated posterior or anterior cataract.

Treatment: No specific measure to prevent progression of renal disease. Treatment includes renal replacement therapy, by long-term hemodialysis or renal transplant. Hearing defect can be temporarily compensated by the use of hearing aid.

TUBULOINTERSTITIAL DISEASES

- **Tubulointerstitial nephropathy** is an **inflammatory condition affecting primarily the renal tubules (Fig. 10.12) and interstitium**.
- **Structural changes in the glomeruli develop later** and results in progressive decline in GFR, glomerular proteinuria and volume-dependent hypertension.
- It accounts for **20–40% of cases of CRF** and **10–25% of cases of ARF.**

FIG. 10.12: Structure of renal tubules.
(ANP: Atrial natriuretic peptide; AVP: Arginine vasopressin)

Acute Tubulointerstitial Nephropathy

Tubulointerstitial nephritis is a frequent cause of AKI that can lead to CKD.

- Affects renal tubules and interstitial components of the renal parenchyma
- *Characterized*: Tubular dysfunction with electrolytes abnormalities (moderate proteinuria, varying degrees of renal impairment)

Two most common causes of acute TIN are **drugs or toxins and infections**.

Etiology (Box 10.13)

Box 10.13: Etiology of acute tubulointerstitial nephropathy.

Drugs

- Antimicrobials
- Analgesics/NSAIDs
- Diuretics
- Anticonvulsants
- Metabolic salts
- Indigenous medication

Infections

- Viral: Cytomegalovirus, hepatitis, HIV, Epstein–Barr virus, hantavirus, polyomavirus
- Bacterial: *Salmonella*, *Streptococcus*, *Yersinia*, *Brucella*, *leptospirosis*
- Fungal: Histoplasmosis
- Parasitic: Leishmania, Toxoplasma

Immunological

- Transplant rejection
- Systemic lupus erythematosus (SLE), Sjögren's syndrome, sarcoidosis

Metabolic

- Hypercalcemia, cystinosis, potassium depletion, hyperoxaluria

Hemopoietic

- Myeloproliferative diseases, plasma cell dyscrasias

Miscellaneous

- Irradiation, heat stroke

Idiopathic

Drug-induced acute TIN

- After exposure to a causative drug, **renal dysfunction may occur within a few hours** but can occur after weeks or months.
- Preceded or accompanied by the triad of **fever** (70–100%), **skin rash** (30–50%) and **eosinophilia (transient).** Skin rash and eosinophilia are not found in TIN caused by NSAIDs.
- **Microscopic hematuria, pyuria, and proteinuria** are present in almost all cases. **Eosinophiluria (>50% of WBC) is a sensitive marker of drug-induced TIN.**
- Patients may need steroids (methylprednisolone 500–1000 mg/day for 3 days).

Analgesic Nephropathy

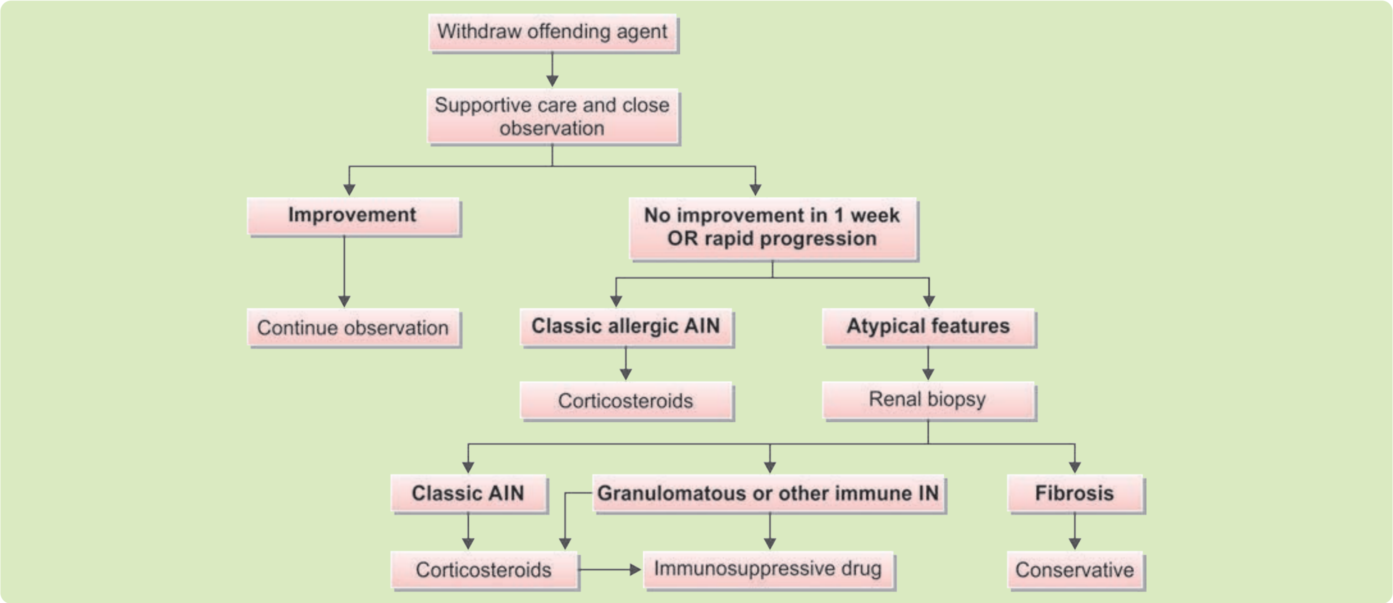
- **Prolonged analgesic abuse** leads to a nephropathic process characterized by **capillary sclerosis, chronic tubulointerstitial diseases and papillary necrosis**.
- Imaging reveals shrunken kidneys with calcification of renal papillae.
- Risk of developing renal disease is **dependent upon** the **frequency and duration of analgesic consumption,** the cumulative amount of individual analgesic exceeding 3 kg (phenacetin, acetaminophen, or aspirin).

Tubulointerstitial Nephritis and Uveitis Syndrome

- Combination of TIN and uveitis
- Abnormal renal function, abnormal urinalysis
- Anterior uveitis—photophobia, eye pain and redness, eyelid edema, rapidly progressive loss of vision, as well as symptoms of systemic illness, including weight loss, fever, and fatigue
- Seen in adolescent girls
- Has good prognosis

Treatment of Interstitial Nephritis (*See* below Flowchart)

- Stop the offending agent
- Prednisone at a dose of 1 mg/kg/day (to a maximum of 40–60 mg) for a minimum of 1–2 weeks, beginning a gradual taper after the serum creatinine has returned to or near baseline.
- Cyclophosphamide (2 mg/kg/d)
- Mycophenolate
- Plasmapheresis.



Withdraw offending agent
Supportive care and close observation
Improvement
No improvement in 1 week OR rapid progression
Continue observation
Classic allergic AIN
Atypical features
Corticosteroids
Renal biopsy
Classic AIN
Granulomatous or other immune IN
Fibrosis
Corticosteroids
Immunosuppressive drug
Conservative

RENAL TUBULAR ACIDOSIS

Q. Write short essay/note on renal tubular acidosis.

- Renal tubular acidosis refers to hyperchloremic (normal anion gap) metabolic acidosis in the presence of normal or almost normal renal function.
- Renal tubular acidosis arises as a result of defects in the tubular transport of HCO_3^- and/or H^+.
- Most forms of RTA are usually asymptomatic; rarely, life-threatening electrolyte imbalances may occur.

Mechanism

Renal tubular acidosis can be due to a defect in one of three processes:

1. **Impaired acid secretion in the late distal tubule** or cortical collecting duct intercalated cells (classical distal RTA).
2. **Impaired bicarbonate reabsorption in the proximal tubule** (proximal RTA).
3. **Impaired sodium reabsorption in the late distal tubule** or cortical collecting duct. It is associated with reduced secretion of both potassium and H^+ ions (hyperkalemia distal RTA).

Box 10.14: Lists types of renal tubular acidosis (RTA).

- Type 1 RTA or distal tubular RTA
- Type 2 RTA or proximal RTA
- Type 3 RTA or mixed RTA
- Type 4 RTA or hypoaldosteronism hyperkalemia RTA

Overview of various forms of renal tubular acidosis

Type of renal tubular acidosis	*Type 1 RTA (distal RTA)*	*Type 2 RTA (proximal RTA)*	*Type 4 RTA (hyperkalemic RTA)*
Incidence	Rare	Very rare	**Common**
Pathophysiology	Inability of intercalated cells of the distal tubule to secrete H^+	Inability of the proximal convoluted tubule cells to reabsorb HCO_3	**Aldosterone** deficiency and/or resistance
Serum potassium levels	**Hypokalemia**	**Hypokalemia**	**Hyperkalemia**
Urine pH	>5.5	<5.5	<5.5
Urine anion gap	Positive	Negative	Positive
Calcium excretion	↑	Normal	Normal or ↓
Bone involvement	Bone demineralization without overt **rickets** or **osteomalacia**	**Vitamin D**-resistant **rickets/ osteomalacia**	Bone demineralization without overt **rickets** or **osteomalacia**
Nephrolithiasis	**Usually present**	Absent	Absent
Treatment	Alkali therapy with **sodium bicarbonate** or sodium citrate (Shohl's solution)	Alkali therapy with orally administered **potassium citrate**	**Furosemide** Mineralocorticoid replacement (fludrocortisone) Low-potassium diet

Types

Type 1 ("Distal" Renal Tubular Acidosis)

- Most common type of RTA.
- **Causes (Box 10.15)**: It occurs due to a failure of H^+ (hydrogen ion) excretion in the distal tubule.

Consequences

- Acidosis
- Hypokalemia (few exceptions)
- Failure to lower the urine pH below 5.3 despite systemic acidosis
- Low urinary ammonium production
- **Renal calculus** formation due to hypercalciuria, hypocitraturia (citrate inhibits calcium phosphate precipitation), and alkaline urine (which favors precipitation of calcium phosphate). Calculus produces hematuria, pain, and recurrent urinary infections.
- Nephrocalcinosis **(Fig. 10.13)**: Deposition of calcium in the kidney parenchyma.
- Depletion/mobilization of calcium (demineralization) from bones causing rickets in children and osteomalacia in adults.

Diagnosis

- Urinary pH >5.3 in presence of systemic acidosis
- Plasma bicarbonate (HCO_3^-) <20 mEq/L
- **Acid load test:**
    - Give ammonium chloride by mouth (100 mg/kg) and check pH of urine hourly and plasma HCO_3^- at 3 hours.
    - Plasma HCO^- should drop below 21 mmol/L.
    - Diagnosis is confirmed if urine pH remains >5.3 despite a plasma HCO_3^- of 21 mmol/L.

Box 10.15: Causes of type 1 renal tubular acidosis (RTA).

- Primary/hereditary
- Nephrocalcinosis (producing damage of cortical collecting duct)
- Chronic urinary tract obstruction
- Hypergammaglobulinemic states
- Drugs and toxins, e.g., ifosfamide, amphotericin B, lithium, and toluene
- Renal transplant rejection
- Autoimmune disease, e.g., Sjögren's syndrome
- Cirrhosis of liver
- Sickle cell anemia

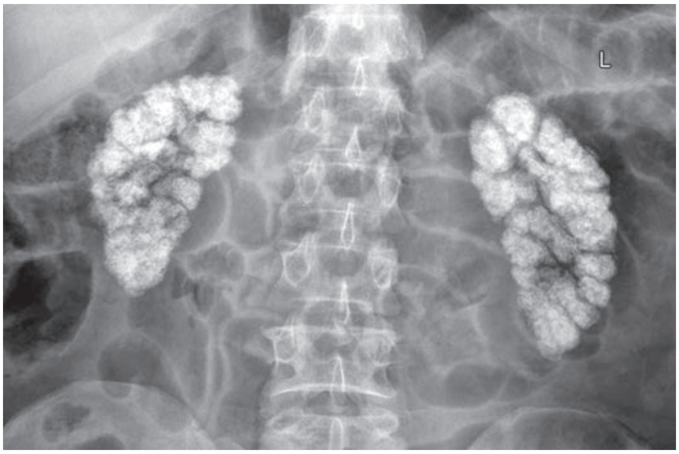


FIG. 10.13: Nephrocalcinosis in type 1 renal tubular acidosis (RTA).

Treatment

- **Correction of the acidosis:** Oral sodium bicarbonate or sodium citrate reverses bone demineralization.
- **Potassium supplements:** Potassium citrate in case of hypokalemia, stone formation, and nephrocalcinosis.
- **Thiazide diuretics:** They cause volume contraction and increased proximal sodium bicarbonate reabsorption.

Type 2 ("Proximal") Renal Tubular Acidosis

- Very rare and is due to **failure of filtered sodium bicarbonate reabsorption** in **the proximal tubule.** It leads to appearance of bicarbonate in urine and subsequent acidosis.
- **Causes of type 2 RTA (Box 10.16)**: Inherited forms of isolated type 2 RTA may show both autosomal dominant and recessive patterns of inheritance.

Consequences: Type 2 RTA usually occurs as part of a generalized tubular defect, together with urinary wasting of amino acids, phosphate, and glucose (Fanconi's syndrome), as well as bicarbonate and potassium.

- Acidosis less severe than type 1 RTA
- Hypokalemia
- Inability to lower the urine pH below 5.5 despite systemic acidosis
- Appearance of bicarbonate in the urine despite a subnormal plasma bicarbonate
- Bone demineralization due to phosphate wasting.

Box 10.16: Causes of type 2 renal tubular acidosis (RTA).

- Inherited
- Paraproteinemia
- Amyloidosis
- Hyperparathyroidism
- Heavy metal toxicity
- Drugs and toxins such as antiretroviral drugs, ifosfamide, lead, and cadmium
- Wilson's disease

Type 3 Renal Tubular Acidosis

- It represents a combination of type 1 and type 2.

Treatment

- **Large/**massive **doses of sodium bicarbonate:** May be required to overcome the renal "leak" of bicarbonate.
- **Potassium supplementation:** Often necessary because loss of bicarbonate in urine potentiates hypokalemia.

- **Inherited type 3 RTA:** It is caused by mutations resulting in carbonic anhydrase type II deficiency. It is characterized by osteopetrosis, cerebral calcification, and mental retardation.

Type 4 Renal Tubular Acidosis

It is also known as "hyporeninemic hypoaldosteronism." Its features are listed in **Box 10.17**.
Causes of type 4 RTA is presented in **Table 10.23**.
Algorithm approach to RTA is presented in **Figure 10.14**.

Box 10.17: Features of type 4 renal tubular acidosis.

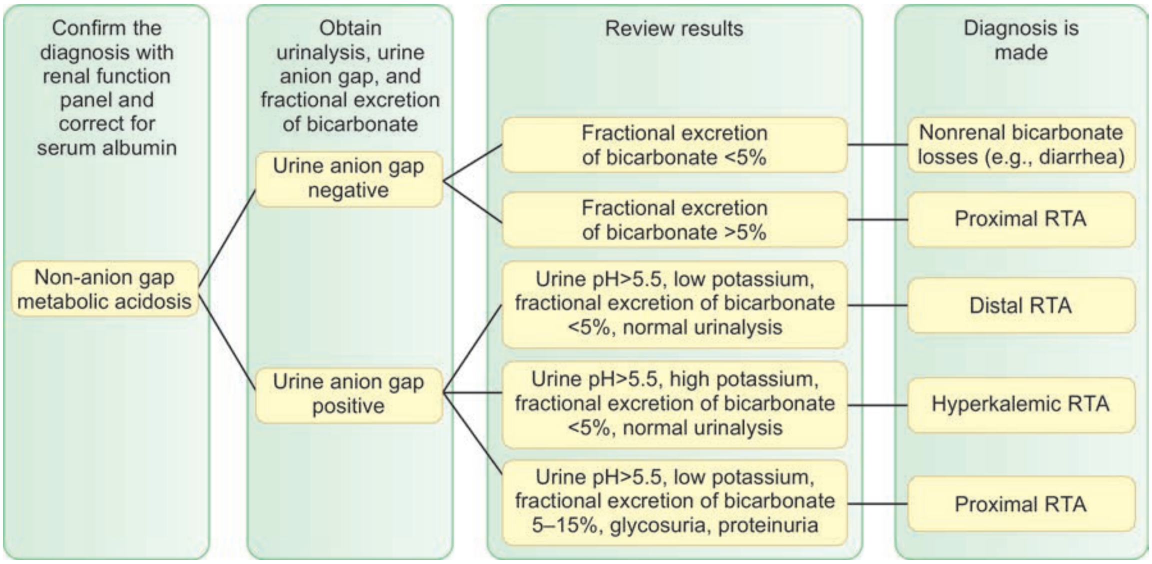
- Hyperkalemia
- Reduced plasma bicarbonate and hyperchloremia
- Normal ACTH stimulation test
- Low basal 24 hours urinary aldosterone
- Reduced response of plasma renin and plasma aldosterone to stimulation
- Correction of hyperkalemia by fludrocortisone

Treatment of type 4 RTA

- Treatment of aldosterone deficiency: With a mineralocorticoid (e.g., fludrocortisones) and glucocorticoid for cortisol deficiency (if present).
- Hyporeninemic hypoaldosteronism by fludrocortisones and accompanying hypertension and edema are treated by thiazide or loop diuretic. Diuretics are also necessary for the control of hyperkalemia.

TABLE 10.23: Causes of type 4 RTA.

Primary aldosterone deficiency	*Hyporeninemic hypoaldosteronism*	*Aldosterone resistance*
➢ Primary adrenal insufficiency ➢ Congenital adrenal hyperplasia ➢ Deficiency of aldosterone synthase ➢ Potassium sparing diuretics	➢ Renal dysfunction (e.g., diabetic nephropathy) ➢ Angiotensin-converting enzyme (ACE) inhibitors ➢ HIV ➢ Nonsteroidal anti-inflammatory drugs ➢ Cyclosporine	➢ Drugs (e.g., amiloride, spironolactone, trimethoprim, pentamidine) ➢ Pseudohypoaldosteronism



Confirm the diagnosis with renal function panel and correct for serum albumin
Obtain urinalysis, urine anion gap, and fractional excretion of bicarbonate
Review results
Diagnosis is made
Non-anion gap metabolic acidosis
Urine anion gap negative
Urine anion gap positive
Fractional excretion of bicarbonate <5%
Fractional excretion of bicarbonate >5%
Urine pH>5.5, low potassium, fractional excretion of bicarbonate <5%, normal urinalysis
Urine pH>5.5, high potassium, fractional excretion of bicarbonate <5%, normal urinalysis
Urine pH>5.5, low potassium, fractional excretion of bicarbonate 5–15%, glycosuria, proteinuria
Nonrenal bicarbonate losses (e.g., diarrhea)
Proximal RTA
Distal RTA
Hyperkalemic RTA
Proximal RTA

FIG. 10.14: Algorithm approach to renal tubular acidosis (RTA).

CHRONIC KIDNEY DISEASE (TABLE 10.24)

Chronic kidney disease previously termed CRF or insufficiency.

Chronic kidney disease refers to a spectrum of **long-standing** (more than 3 months), usually **progressive** processes associated with **irreversible worsening of renal function** and decline in GFR. **CKD spectrum ranges from abnormalities detectable only by laboratory testing to uremia.**

IM10.6 Stages of Chronic Kidney Disease

Revised CKD classification based upon GFR and albuminuria KDIGO 2013 is presented in **Figure 10.15**.

TABLE 10.24: Classification of CKD (The National Kidney Foundation-Kidney Disease Outcomes Quality Initiative NKF-KDOQI) working group.

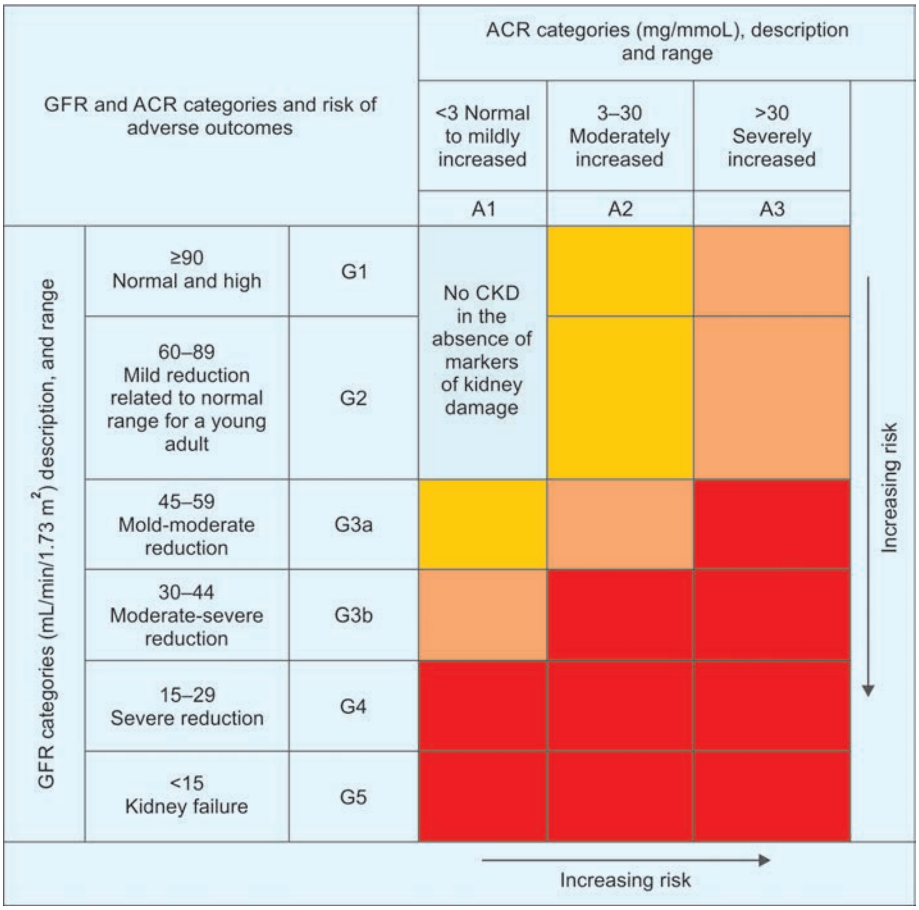
Stage	*Description*	*GFR (mL/minute/1.73 m^2)*
1	Chronic kidney damage with normal or increased GFR	>90
2	Mild GFR loss	60–89
3	Moderate GFR loss *stage 3A (GFR: 45–59 mL/min) and stage 3B (GFR: 30–44 mL/min)*	30–59
4	Severe GFR loss	15–29
5	Kidney failure requiring dialysis *(5D)* or transplantation *(5T)*	<15

Definition (Box 10.18)

Q. Discuss the clinical and biochemical features of chronic kidney disease (CKD).

Box 10.18: Definition of chronic kidney disease (CKD).

- Glomerular filtration rate (GFR) of <60 mL/minute/1.73 m^2 for 3 months or more, with or without kidney damage or a urinary albumin to creatinine ratio >65 mg/mmol or protein creatinine ratio of 100 mg/mmol.
  OR
- Kidney damage for 3 or more months with or without decreased GFR, as evidenced by any of the following:
  - **Microalbuminuria:** Albumin excretion rate 30–300 mg/day in urine or urinary albumin >30 mg/day excretion of creatinine.
  - **Macroalbuminuria:** Albumin excretion rate in urine 300 mg/day.
  - **Pathologic abnormalities** such as abnormal findings on renal biopsy.
  - **Radiologic abnormalities** such as scarring or polycystic kidneys on renal ultrasound scan.



GFR and ACR categories and risk of adverse outcomes			ACR categories (mg/mmoL), description and range		
			<3 Normal to mildly increased	3–30 Moderately increased	>30 Severely increased
			A1	A2	A3
GFR categories (mL/min/1.73 m^2) description, and range	≥90 Normal and high	G1	No CKD in the absence of markers of kidney damage	🟨	🟧
	60–89 Mild reduction related to normal range for a young adult	G2		🟨	🟧
	45–59 Mold-moderate reduction	G3a	🟨	🟧	🟥
	30–44 Moderate-severe reduction	G3b	🟧	🟥	🟥
	15–29 Severe reduction	G4	🟥	🟥	🟥
	<15 Kidney failure	G5	🟥	🟥	🟥

FIG. 10.15: Revised chronic kidney disease classification based upon glomerular filtration rate (GFR) and albuminuria (KDIGO). (ACR: Albumin-to-creatinine ratio)

Causes of Chronic Kidney Disease

See **Table 10.25.**

Q. IM10.5 Describe and discuss the etiology of CRF.

Clinical Approach to Chronic Kidney Disease

History

- Duration of symptoms
- Drug intake: These include nonsteroidal anti-inflammatory agents, analgesic, and other medications (e.g., herbal medicines).
- Previous medical and surgical history, e.g., chemotherapy, SLE, malaria.
- Previous urinalysis or urea and creatinine values if performed.
- Family history of renal disease.

TABLE 10.25: Important causes of chronic kidney disease.

I. **Glomerulopathies*** Proliferative glomerulonephritis (GN), crescentic GN, membranoproliferative GN, mesangiocapillary GN	IV. **Obstructive*** Calculus tumors, retroperitoneal fibrosis, prostatic enlargement
II. **Systemic and metabolic diseases** Diabetes* Systemic lupus erythematosus (SLE), polyarteritis nodosa (PAN), amyloidosis Gout	V. **Vascular** Essential hypertension (accelerated)*, renovascular vasculitis (SLE, PAN, scleroderma)
III. **Interstitial** Chronic interstitial nephritis*, chronic pyelonephritis*, analgesic Tuberculosis, nephrocalcinosis	VI. **Congenital** Polycystic kidney*, medullary cystic disease, Alport's syndrome

*Common causes of chronic renal failure.

Symptoms

- Unfortunately, **early stages** of CKD **may be asymptomatic**, despite the progressive loss of kidney function and accumulation of numerous metabolites.
- Usually there is a rough correlation between serum urea and creatinine levels and symptoms. Symptoms are common when the serum urea level exceeds 40 mmol/L.

Clinical Features (Table 10.26 and Fig. 10.16)

Q. M10.7 Describe and discuss the pathophysiology and clinical findings of uremia.

TABLE 10.26: Clinical features of chronic kidney disease (CKD).

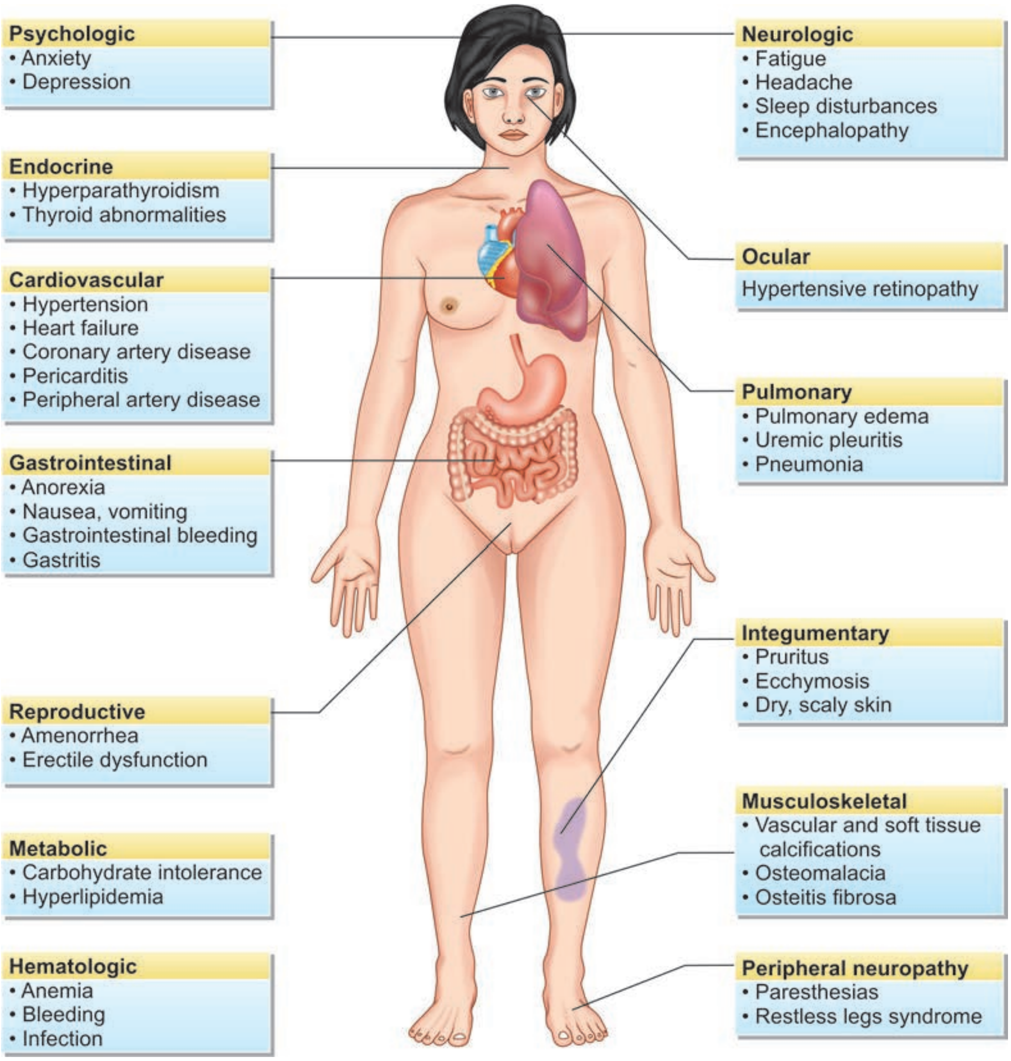
System	*Clinical features*	*Cause*
Renal	Nocturia and polyuria	Impaired concentrating ability of kidney
Muscle	Generalized myopathy	Combination of poor nutrition, hyperparathyroidism and vitamin D deficiency
Gastrointestinal	Malaise, loss of appetite (anorexia), nausea, vomiting, diarrhea	Nitrogenous waste products
Metabolic	Paresthesia and tetany	Hypocalcemia
Endocrine	Loss of libido in both sexes Women: Amenorrhea, menorrhagia Males: Erectile dysfunction, oligospermia	Hypothalamic-pituitary axis dysfunction
Skeletal	Bone pain	Metabolic bone disease
Respiratory	Pleural effusion, interstitial lung disease, calcification	Salt and water retention
Hematologic	Symptoms due to anemia: Fatigue, lassitude	Anemia is normochromic and normocytic type. Various causes mentioned in **Table 10.32**
Skin	Pruritus/itching, rash, metastatic calcification	Retention of nitrogenous waste products of protein catabolism, hyperparathyroidism, calcium-phosphate deposition
Immune system	Infections	Leukocyte functional defects, reduced cellular immunity
Cardiovascular	Atherosclerosis, heart failure, hypertension	Hypertension, homocysteinemia, calcification of heart valves
Neurologic	Peripheral neuropathy, mental slowing, clouding of consciousness and seizures myoclonic twitching, coma, restless leg syndrome or sensory deficits	Uremic toxins
Serosal inflammation	Pericardial or pleural pain and fluid, peritoneal fluid	Water retention

Complications of Chronic Renal Failure

Q. Write short essay/note on the complications of chronic renal failure.

Anemia: Various causes of anemia in CRF are listed in **Box 10.19**.

Q. Write short essay/note on renal osteodystrophy.



Psychologic
• Anxiety
• Depression
Endocrine
• Hyperparathyroidism
• Thyroid abnormalities
Cardiovascular

• Osteomalacia
• Osteitis fibrosa
Peripheral neuropathy
• Paresthesias
• Restless legs syndrome

FIG. 10.16: Various clinical manifestations of chronic kidney disease (CKD).

Metabolic Bone Disease: Renal Osteodystrophy

The term "renal osteodystrophy" (bone mineral disorder), constitutes various forms of bone disease that may develop alone or in combination in CRF. It includes (1) hyperparathyroid bone disease (osteitis fibrosa cystica), (2) osteomalacia, (3) osteoporosis, (4) osteosclerosis, and (5) adynamic bone disease.

Pathogenesis of CKD—MBD (metabolic bone disease) (Fig. 10.17)

- Phosphate retention owing to reduced excretion by the kidneys release of **fibroblast growth factor 23 (FGF 23)** and other phosphaturic agents by osteoblasts as a compensatory mechanism. Actions of FGF 23 are:
  - Causes phosphaturia to normalize the plasma phosphate level.
  - It downregulates 1α-hydroxylase to reduce intestinal absorption of phosphate.
- Decreased production of the lα-hydroxylase enzyme by the kidney results in reduced conversion of 25-$(OH)_2D_3$ (25-hydroxyvitamin D) to the more metabolically active 1,25-$(OH)_2D_3$(1,25-dihydroxycholecalciferol). Its consequences are:
  - Decreased activation of vitamin D receptors (VDRs) in the parathyroid glands leads to increased release of parathyroid hormone (PTH) causing secondary hyperparathyroidism.

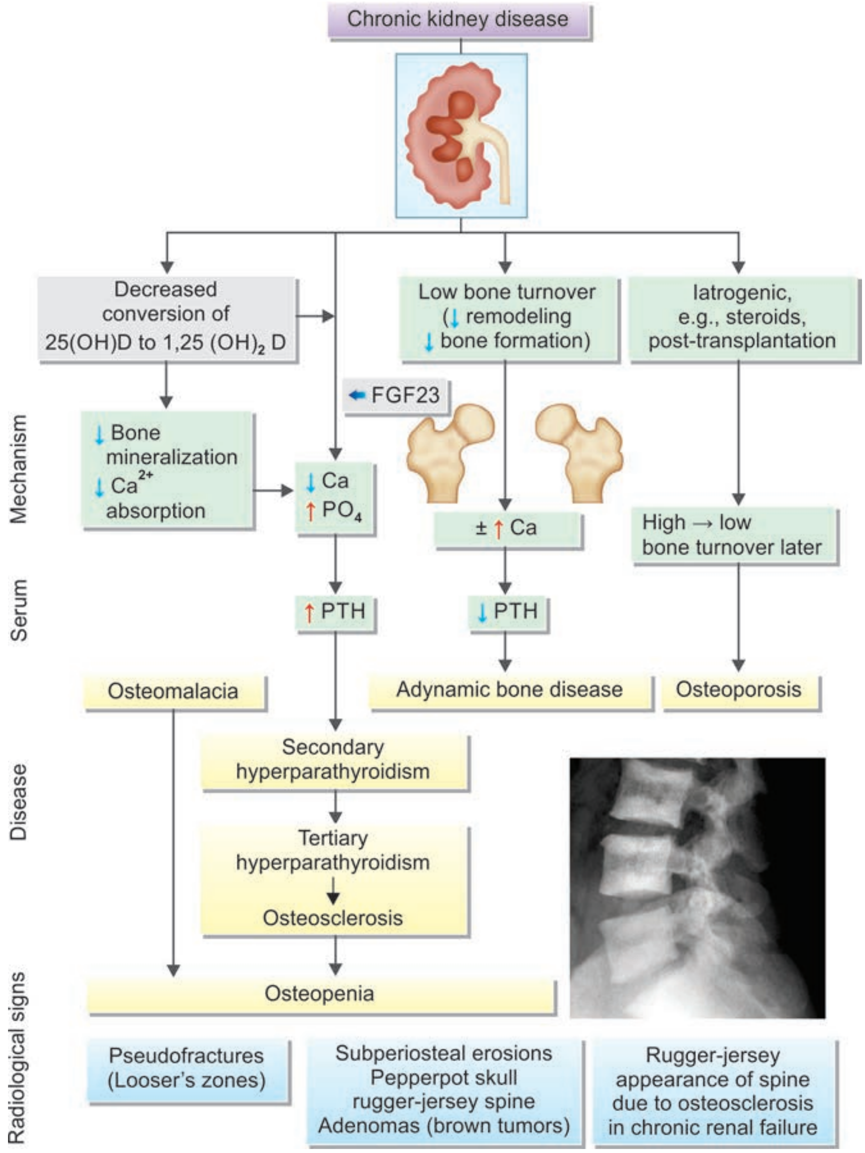
Box 10.19: Causes of anemia in chronic renal failure (CRF).

- Deficiency of erythropoietin (most important)
- Toxic effects of uremia on bone marrow precursor cells
- Bone marrow fibrosis secondary to hyperparathyroidism
- Deficiency of hematinic: Iron, vitamin B_{12}, folate because of reduced dietary intake due to anorexia. Intestinal absorption of iron is also impaired.
- Increased red cell destruction: Abnormal red cell membranes
- Increased blood loss
  - Occult gastrointestinal bleeding
  - Blood sampling
  - Blood loss during hemodialysis
  - Capillary fragility
  - Due to platelet dysfunction and capillary fragility

  - Decreased intestinal absorption of calcium causes hypocalcemia which leads in turn to increased PTH production by the parathyroid glands.
  - Phosphate retention also indirectly lowers ionized calcium and these together results in an increase in PTH synthesis and release. The raised serum phosphate combine with calcium in the extracellular space, causing ectopic calcification in blood vessels and other tissues.
  - Parathyroid hormone causes reabsorption of calcium from bone and increased reabsorption of calcium from proximal renal tubules.

This prevents hypocalcemia induced by 1,25-$(OH)_2D_3$ deficiency and phosphate retention.

- **Secondary hyperparathyroidism** causes increased osteoclastic activity, cyst formation and bone marrow fibrosis (osteitis fibrosa cystica).
- Long-standing secondary hyperparathyroidism finally causes hyperplasia of the glands with autonomous or **"tertiary" hyperparathyroidism**.
- **Osteomalacia:** It is due to impaired mineralization of osteoid caused by deficiency 1,25-$(OH)_2D_3$ and hypocalcemia.
- **Osteosclerosis:** Literally means "hardening of bone" characterized by increased bone density and is due to the direct result of long-standing PTH excess. Alternating bands of sclerotic and porotic bone in the spine give rise to a characteristic **"rugger-jersey"** appearance on X-ray **(Fig. 10.17)**.



Chronic kidney disease
Decreased conversion of 25(OH)D to 1,25 $(OH)_2$ D
Low bone turnover (↓ remodeling ↓ bone formation)
Iatrogenic, e.g., steroids, post-transplantation
← FGF23
Mechanism
↓ Bone mineralization ↓ Ca^{2+} absorption
↓ Ca ↑ PO_4
± ↑ Ca
High → low bone turnover later
Serum
↑ PTH
↓ PTH
Osteomalacia
Adynamic bone disease
Osteoporosis
Disease
Secondary hyperparathyroidism
Tertiary hyperparathyroidism
Osteosclerosis
Radiological signs
Osteopenia
Pseudofractures (Looser's zones)
Subperiosteal erosions Pepperpot skull rugger-jersey spine Adenomas (brown tumors)
Rugger-jersey appearance of spine due to osteosclerosis in chronic renal failure

FIG. 10.17: Lateral spine X-ray showing rugger-jersey appearance of spine.

[25-$(OH)D_3$: 25-hydroxyvitamin D; 1,25-$(OH)_2D_3$: 1,25-dihydroxycholecalciferol; FGF23: Fibroblast growth factor 23; Ca: Calcium; PO_4: Phosphate; PTH: Parathormone]

- **Osteoporosis** is probably related to malnutrition and is commonly found in CRF, often after transplantation and the use of corticosteroids.
- **Adynamic bone disease** is the condition of in which both bone formation and resorption are depressed.

Role of Fibroblast Growth Factor in CKD-MBD

- According to new phosphate-centric paradigm, CKD causes a decrease in renal phosphate excretion which leads to increased fibroblast growth factor-23 (FGF-23) from bone osteocytes. FGF-23 act on kidney to inhibit phosphate reabsorption and also suppress production of active vitamin D to lower GI absorption of phosphorous.
- Kidney failure leads to decreased phosphorus clearance in the absence of dietary phosphorus restriction, resulting in increased FGF-23 secretion in early kidney failure in order to maintain normal phosphorus balance by increasing urinary phosphate excretion and inhibiting the synthesis of 1,25-dihydroxyvitamin D.
- Decreased circulating 1,25-dihydroxyvitamin D concentrations and eventually low serum calcium in turn stimulate increased parathyroid hormone concentrations levels in early kidney failure, with the effects of phosphate retention on increased parathyroid hormone secretion and low calcium being more prominent in later stages of kidney disease.

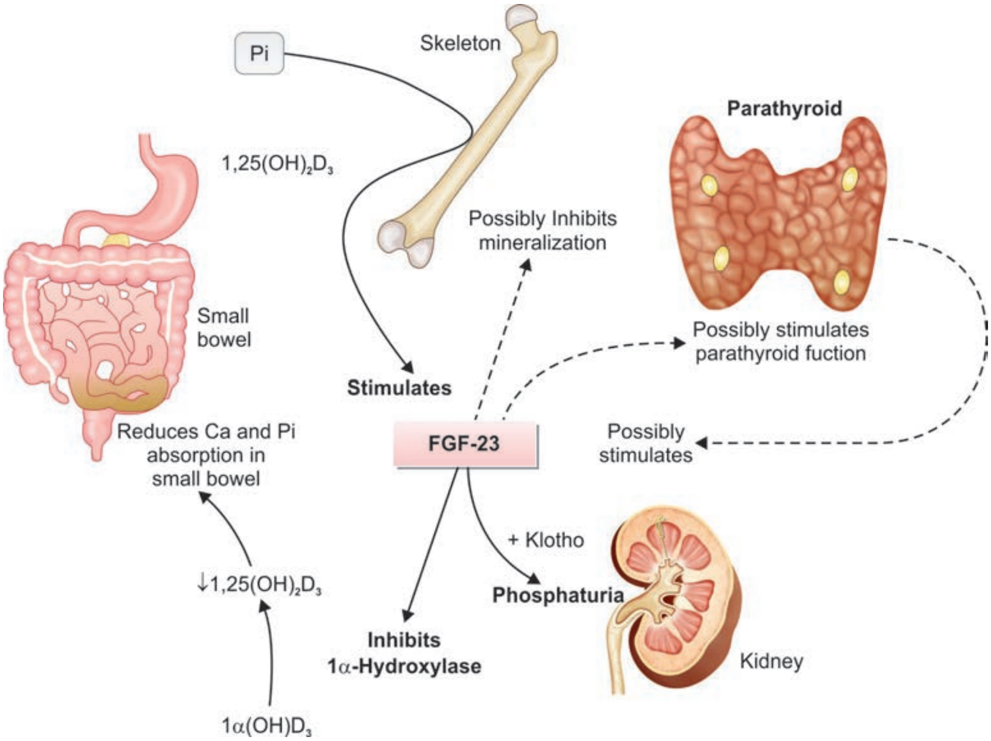


FIG. 10.18: Pathophysiology of CKD-MBD.

Klotho in Chronic Kidney Disease

- Alpha-Klotho (α-Klotho) protein is encoded by the gene, Klotho, and functions as a coreceptor for endocrine fibroblast growth factor-23.
- The extracellular domain of α-Klotho is cleaved by secretases and released into the circulation where it is called soluble α-Klotho. Soluble α-Klotho in the circulation starts to decline in chronic kidney disease (CKD) stage 2 and urinary α-Klotho in even earlier CKD stage 1.
- Therefore soluble α-Klotho is an early and sensitive marker of decline in kidney function.
- α-Klotho deficiency ais a pathogenic factor for CKD progression and extrarenal CKD complications including cardiac and vascular disease, hyperparathyroidism, and disturbed mineral metabolism.
- Klotho holds a promising therapeutic effect to mitigate CKD progression, AKI-to-CKD progression, and alleviate cardiovascular disease, being the latter the principal culprit of elevated mortality in CKD/ESRD patients.

Gastrointestinal complications: (1) Reduced gastric emptying and increased risk of reflux esophagitis, (2) increased risk of peptic ulceration and acute pancreatitis, and (3) constipation (especially in patients on continuous ambulatory peritoneal dialysis (CAPD), and (4) gastrointestinal bleed.

- **Metabolic abnormalities:**
  - **Gout:** Urate retention is a common in CRF.
  - **Insulin requirement and resistance:** Insulin is catabolized by and to some extent excreted via the kidneys. Thus, insulin requirements in diabetic patients reduce as renal failure progresses. By contrast, end-organ resistance to insulin is observed in advanced renal impairment.
- **Lipid metabolism abnormalities:** Include (1) impaired clearance of triglyceride-rich particles and (2) hypercholesterolemia.
- **Endocrine abnormalities:** Include (1) Hyperprolactinemia, (2) increased luteinizing hormone (LH) levels in both sex, (3) decreased serum testosterone levels, (4) absence of normal cyclical changes in female sex hormones, resulting in oligomenorrhea or amenorrhea, (5) abnormalities of growth hormone secretion and action, and (6) abnormal thyroid hormone levels.
- **Muscle dysfunction proximal myopathy.**
- **Nervous system**
  - *Central nervous system:*
    - Unusual combination of depressed cerebral function and decreased seizure threshold.
    - **Dialysis disequilibrium** develops if rapid correction of severe uremia is done by hemodialysis owing to osmotic cerebral swelling.
    - **Dialysis dementia** is a syndrome characterized by progressive intellectual deterioration, speech disturbance, myoclonus, and fits.
  - *Autonomic nervous system:* (1) Increased circulating catecholamine level, (2) impaired baroreceptor sensitivity, and (3) impaired efferent vagal function.
  - *Peripheral nervous system:* (1) Median nerve compression in the carpal tunnel due to β_2-microglobulin-related amyloidosis, (2) restless legs syndrome, (3) polyneuropathy, and (4) psychiatric problems (anxiety, depression, phobias, and psychoses).
- **Cardiovascular disease: Increased (16-fold) incidence of cardiovascular disease,** particularly myocardial infarction, cardiac failure, sudden cardiac death and stroke, uremic pericarditis or dialysis pericarditis. Hypertension develops in about 80% of patients with CRF.
- **Malignancy: Raised** incidence of malignancy. Malignant change can occur in polycystic kidney disease. Lymphomas, primary liver cancer, and thyroid cancers can also develop.

Investigations (Box 10.20)

Box 10.20: Purpose of investigations in chronic renal failure.

- To identify the underlying cause wherever possible.
- To identify reversible factors (e.g., hypertension, urinary tract, obstruction, nephrotoxic drugs, and salt and water depletion).
- To screen for complications (e.g., anemia, renal osteodystrophy) and cardiovascular risk factors.

Urinalysis

- **Physical examination:** Fixed specific gravity around 1.010 (isosthenuria) is seen in CRF.
- **Chemical examination**
  - Hematuria may indicate glomerulonephritis.
  - Proteinuria, if heavy, is strongly suggestive of glomerular disease.
  - Glycosuria with normal blood glucose level is common in CRF.
- **Urine microscopy**
  - **White cells** in the urine usually indicate **bacterial urinary infection**, sterile pyuria suggests papillary necrosis or renal tuberculosis.
  - **Eosinophils** indicate **allergic tubulointerstitial nephritis** or cholesterol embolization.
  - **Red cells** source may be from anywhere in the urinary tract between the glomerulus and the urethral meatus.
  - **Red cell casts** are suggestive of **glomerulonephritis**.
  - **Granular casts** indicate **active renal disease**.
  - **Broad casts** are seen in CRF.
- **Urine culture** should be performed. Early-morning urine samples should be cultured for tuberculosis.

Urine Biochemistry

- **24-hour creatinine clearance** is useful to know the severity of renal failure.
- **Urine osmolality** is a measure of concentrating ability.
- **Urine electrophoresis** and immunofixation for the detection of light chains in myeloma.

Serum Biochemistry

- **Serum urea and creatinine:** The most consistent abnormalities in CRF are **elevated** levels of urea and creatinine. The level of serum creatinine correlates with the degree of renal damage.
- **Electrophoresis and immunofixation for myeloma**.
- Extreme elevations of creatine kinase and a disproportionate elevation in serum creatinine and potassium compared to urea suggestive of rhabdomyolysis.
- Other biochemical abnormalities include hypocalcemia, hyperphosphatemia, hyperuricemia and hyperkalemia.

Hematology

- **Anemia**
- **Eosinophilia** suggestive of allergic TIN, vasculitis, or cholesterol embolism.
- **Peripheral smear** with **fragmented red cells (Burr cells) and/or thrombocytopenia** suggestive of **intravascular hemolysis** due to accelerated hypertension, hemolytic uremic syndrome or thrombotic thrombocytopenic purpura.
- **Markedly raised erythrocyte sedimentation rate (ESR)** is suggestive of **myeloma**.

Immunology

- **Low complement components** may be seen in **active glomerular disease** (e.g., SLE, PSGN).
- **Autoantibody screening** helpful autoimmune diseases (e.g., SLE).
- **Antibodies to streptococcal antigens** (ASOT, anti-DNase B) if PSGN is suspected.
- **Antibodies to hepatitis B and C**
- **Antibodies to HIV** when HIV-associated renal disease is suspected.
- **Malaria** can cause glomerular disease in the tropics.

Radiological Investigation

- **Ultrasound:** Ultrasonography to assess the renal size and to exclude hydronephrosis. Renal ultrasound usually shows shrunken kidneys in CRF. *In diabetic glomerulosclerosis, amyloidosis, polycystic kidney diseases, HIV nephropathy, bilateral hydronephrosis, and myeloma, the kidneys may be of normal size.*
- **Plain abdominal radiography and CT** (without contrast) to exclude low-density renal stones or nephrocalcinosis. CT may also useful for the diagnosis of retroperitoneal fibrosis and useful in some patients with suspected obstructive nephropathy.
- **MRI:** Magnetic resonance angiography is useful in renovascular disease.

Renal Biopsy

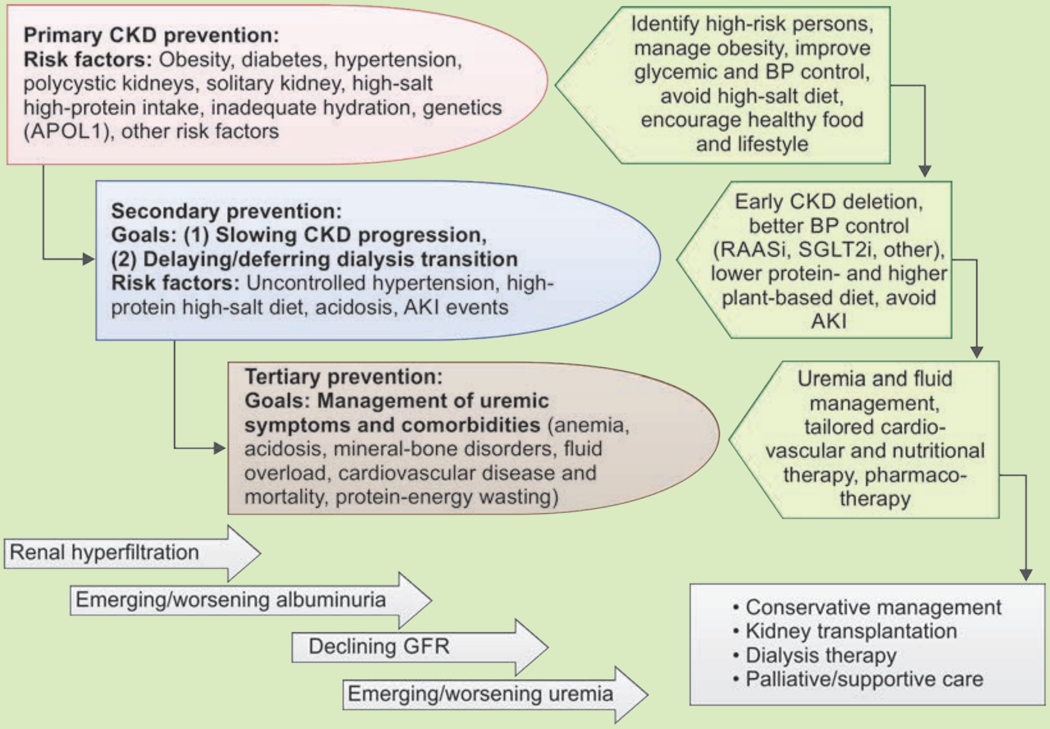
Aim: To establish the nature and extent of renal disease, which helps in treatment and predicting prognosis. It should be performed in patient with unexplained renal failure and normal-sized kidneys (exception diabetic glomerulosclerosis), unless there are strong contraindications.

Q. IM10.26 Describe and discuss supportive therapy in CKD including diet, antihypertensives, glycemic therapy, dyslipidemia, anemia, hyperkalemia, hyperphosphatemia and secondary hyperparathyroidism.

Management of Chronic Renal Failure

Management of CRF can be divided into three parts:

1. Establishing the diagnosis and etiology of CKD and to detect any reversible factors
2. Measures to prevent/slow down the further damage to the kidney (progression of CKD)
3. Supportive measures (e.g., dialysis or transplantation) when necessary



Primary CKD prevention:
Risk factors: Obesity, diabetes, hypertension, polycystic kidneys, solitary kidney, high-salt high-protein intake, inadequate hydration, genetics (APOL1), other risk factors
Identify high-risk persons, manage obesity, improve glycemic and BP control, avoid high-salt diet, encourage healthy food and lifestyle
Secondary prevention:
Goals: (1) Slowing CKD progression, (2) Delaying/deferring dialysis transition
Risk factors: Uncontrolled hypertension, high-protein high-salt diet, acidosis, AKI events
Early CKD deletion, better BP control (RAASi, SGLT2i, other), lower protein- and higher plant-based diet, avoid AKI
Tertiary prevention:
Goals: Management of uremic symptoms and comorbidities (anemia, acidosis, mineral-bone disorders, fluid overload, cardiovascular disease and mortality, protein-energy wasting)
Uremia and fluid management, tailored cardio-vascular and nutritional therapy, pharmaco-therapy
Renal hyperfiltration
Emerging/worsening albuminuria
Declining GFR
Emerging/worsening uremia
• Conservative management
• Kidney transplantation
• Dialysis therapy
• Palliative/supportive care

Treatments aimed at specific causes of CKD: Optimization glucose control in diabetes mellitus, immunomodulatory agents for glomerulonephritis, and emerging specific therapies to retard cytogenesis in polycystic kidney disease. Any reversible factors should be detected and treated (**Table 10.27**).

TABLE 10.27: Reversible factors in chronic kidney disease.

1.	Hypovolemia: Vomiting, diarrhea, excessive diuresis, congestive heart failure
2.	Urinary tract obstruction: Nephrolithiasis, papillary necrosis, bladder outlet obstruction
3.	Infection
4.	Uncontrolled or accelerated hypertension
5.	Nephrotoxic drugs: Aminoglycosides, cephalosporins, tetracycline, amphotericin, radio-contrast agents, NSAIDs, diuretics
6.	Electrolyte and metabolic disorders: Hyperphosphatasemia, hyperuricemia, acidosis
7.	Vasculitis: Systemic lupus erythematosus, Wegener's granulomatosis, microscopic polyarteritis
8.	Pregnancy: Eclampsia

Measures to Reduce the Symptoms and Progression of CRF

- Following measures may stabilize or slow the decline of renal function.
- **Control of hypertension and proteinuria:** Goals of treatment include: (1) blood pressure should be reduced <130/80 mm Hg and proteinuria < 0.3 g/24 hours. If creatinine is below 3 mg/dL, ACE inhibitors and ARBs (inhibit the angiotensin-induced vasoconstriction of the efferent arterioles of the glomerular microcirculation) are the drugs of choice.
- **Diet**
  - **Protein restriction** to 0.60 and 0.75 g/kg/day, i.e., about 40 g/day (with higher amount of essential amino acids). It reduces symptoms associated with uremia and may also slow the rate of renal decline at earlier stages of renal disease.
  - **Avoid foods with high potassium**.
  - **Salt restriction** is necessary in most of the patients. However, patients with salt-losing nephropathy (tubulointerstitial disease) require a high-salt intake.
- **Slowing progression of diabetic renal disease** by control of blood glucose and maintaining HbA1c in the range of 7.0–7.5.
- **Use of lipid-lowering agents:** Hypercholesterolemia is common in patients with significant proteinuria, and in patients with CKD. Lipid lowering reduces vascular events in nondialysis CKD.
- Cessation of smoking.
- Exercise and weight reduction.
- Avoid nephrotoxic medications.

Corrections of complications

Calcium and phosphate control and suppression of PTH

- **Treatment of hypocalcemia and hyperphosphatemia:** Both should be treated aggressively.
  - **Hypocalcemia:**
    - Treated with calcitriol or alphacalcidol (1-α-hydroxyvitamin D$_3$) or paricalcitol (19-nor-1,25-dihydroxyvitamin D$_3$) and calcium supplementation.
    - Serum calcium level should be monitored to avoid hypercalcemia. Oral calcium carbonate also decreases the bioavailability of dietary phosphates.
  - **Hyperphosphatemia:** Treated with phosphate binders. Previously, aluminum hydroxide was used to bind phosphate in the gut and was producing aluminum toxicity. Others include:
    - Calcium carbonate and calcium acetate (serum calcium should be monitored).
    - Polymer sevelamer carbonate (an anion-exchange resin).
    - Lanthanum carbonate (a nonaluminum, noncalcium phosphate-binding agent) has higher incidence of side effects.
- **Treatment of hyperparathyroidism:** By the use of
  - Calcium carbonate or acetate.
  - Vitamin D analogs.
  - Calcimimetics activate the calcium-sensing receptor in the parathyroid gland, thereby inhibiting PTH secretion. Cinacalcet is used in patients who are on dialysis.

Maintenance fluid and electrolyte balance

- **Fluid retention:** If there is evidence of fluid retention intake of dietary sodium is restricted and loop diuretics may be necessary.
- **Hyperkalemia:** Usually responds to dietary restriction of potassium intake. Occasionally, ion-exchange resins may be necessary to remove potassium in the gastrointestinal tract. If hyperkalemia occurs during diuretic therapy, reduce or stop potassium-sparing diuretics, ACE inhibitors, and ARBs.
- **Acidosis:** Sodium bicarbonate may be effective, but can cause edema and hypertension owing to extracellular fluid expansion. Calcium carbonate, also used as a calcium supplement and phosphate binder is useful in treating acidosis.

Q. Write short essay/note on the management of anemia in chronic renal failure.

Treatment of anemia in chronic renal failure

- The anemia of erythropoietin (EPO) deficiency is treated with recombinant (synthetic) human EPO (erythropoietin-alpha or -beta, or the longer-acting darbepoetin-alpha). Administration of erythropoietin-alpha through subcutaneous route is contraindicated in CRF and the intravenous route is used, initially 50 U/kg of epoetin-alpha over 1–5 minutes three times/week. EPO is less effective in the presence of iron deficiency, active inflammation or malignancy, and in patients with aluminum overload (found in dialysis).

	Initiation dose in CKD—nondialysis dependent	**Initiation dose in dialysis dependent CKD**
• Erythropoietin	• 20–50 U/kg 3 times/week (If given IV, IV dose is 20–30% higher than SC dose)	
• Darbepoetin alpha	0.45 mcg/kg every 4 weeks (SC or IV)	0.45 mcg/kg once weekly (SC or IV) Or 0.75 mcg/kg every 2 weeks (SC or IV)
• Epoetin beta	• 0.6 mcg every 2 weeks (SC or IV)	

- Blood pressure, hemoglobin concentration and reticulocyte count are measured every 2 weeks and the dose adjusted to maintain a target hemoglobin level of 10–12 g/dL.
- Hemoglobin >13 g/dL has been associated with increased incidence of cardiovascular mortality.
- Some newer agents tried in management of anemia in CKD:
  - **Prolyl hydroxylase inhibitors:** Roxadustat, vadadustat
  - **Erythropoietin mimicking peptide:** Peginesatide
- **Specific treatment:** Renal replacement therapy

Table 10.28 lists the differences between AKI and CKD.

TABLE 10.28: Differences between acute kidney injury (AKI) and chronic kidney disease (CKD).

	AKI	***CKD***
Previous history of kidney disease	Absent	Present
Previous elevated creatinine >3 months	Absent	Present
Anemia	Absent	Present
Hypertension	+/–	++
Kidney size (ultrasound)	Not contracted	Contracted
Complications: Hyperphosphatemia, hypocalcemia, neuropathy, osteodystrophy, band keratopathy	Absent	Present

CYSTIC DISEASES OF KIDNEY

Polycystic Kidney Diseases

Types: Two types

1. **Autosomal-recessive (childhood) polycystic kidney disease (ARPKD):**
    - Mutation in PKHD1 gene on chromosome 6, the gene that encodes for fibrocystin and biliary epithelial tissue
    - All patients also have cysts in the liver and patients who survive infancy may develop **congenital hepatic fibrosis** and intrahepatic bile duct dilatation (Caroli disease).
2. **Autosomal-dominant (adult) polycystic kidney disease (ADPKD):**
    - ADPKD is the MC inherited renal disease
    - ADPKD is caused by mutations in
        - *PKD1* on chromosome 16 codes for polycystin-1 (PC1)
        - *PKD2* on chromosome 4 codes for polycystin-2 (PC2)
        - 10% patients may have no family history; due to spontaneous mutation
        - PKD2: Slower disease progression
    - It characterized by **multiple thin-walled, spherical cysts in cortex and medulla of both kidneys.** These cysts expand and cause destruction of kidney parenchyma and leads to renal failure.
    - Associated extrarenal anomalies:
        - **Cysts in other organs** such as liver (**polycystic liver disease** in more than 75% of cases) spleen, pancreas, thyroid, ovary, endometrium, seminal vesicles, and epididymis.
        - Intracranial **Berry aneurysms** in the circle of Willis (in 10–30%) which may rupture and cause subarachnoid hemorrhages.
        - **Mitral valve prolapse** and other cardiac valvular anomalies. Colonic diverticula, abdominal or inguinal hernias are associated.
    - **Clinical presentation**

Q. Discuss the clinical features and complications of adult polycystic kidney disease.

- May be at **any age** from the second decade and majority of patients remain **asymptomatic until the fourth decade** of life.
- **Presenting manifestations**
    - Acute loin/**flank pain** (heaviness or dragging sensation), and/or hematuria (owing to hemorrhage into a cyst), UTI (pyelonephritis and renal cyst infection) or urinary tract stone formation and renal colic (due to passage of blood clots in the urine).
    - Vague abdominal/loin or discomfort due to increased size of the kidneys
    - **Subarachnoid hemorrhage** due to rupture of berry aneurysm
    - Renal hemorrhage and hematuria
    - **Hypertension** and its complications
    - Complications of associated liver cysts
    - When sufficient quantity of nephrons are destroyed, patient develops **CKD** and symptoms of uremia and/or anemia
    - **Polycythemia** (due to increased erythropoietin production) is a rare complication and presentation of ADPKD.
    - Rarely renal carcinoma
- **Physical examination:** Bilateral large **abdominal masses** of irregular kidneys.
- **Investigations:**
    - **Abdominal ultrasound** is used for establishing the definitive diagnosis.
    - **MRI** is more sensitive than ultrasound and can detect small cysts **(Fig. 10.19)**.
    - **IVU:** Rarely performed nowadays and may demonstrate the characteristic "drooping water-lily sign."
- **Screening:** The children of patients with established ADPKD should undergo screening.

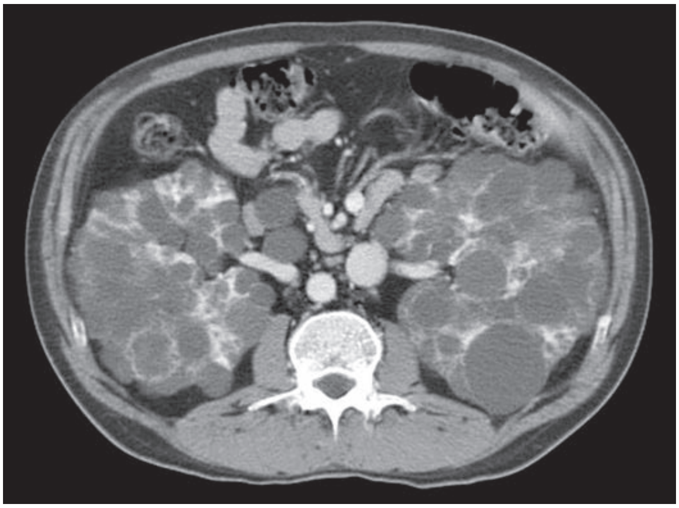


FIG. 10.19: MRI showing polycystic kidney.

Medullary Sponge Kidney

Treatment
- Control of hypertension
- Control of pain
- Treatment of infection
- Management of CKD—dialysis or transplantation (if required) and
- Specific treatment—vaptans, mammalian target of rapamycin (mTOR) inhibitors (sirolimus, everolimus), and somatostatin analogs have been tried in treatment of ADPKD.

- Medullary sponge kidney (MSK) is characterized by nonprogressive dilatation of collecting ducts and tubules.
- Usually inherited as autosomal dominant
- May be associated with other developmental and genetic disorders
- Often asymptomatic, and may manifest with hematuria, nephrolithiasis, and infection.

Medullary Cystic Disease or Juvenile Nephronophthisis

- Two distinct genetic and age-related forms with similar renal morphology. Autosomal recessive manifests during childhood and is frequently associated with extrarenal abnormalities such as ophthalmologic, mental retardation, cerebellar ataxia, skeletal anomalies, and hepatic fibrosis.
- The disease progresses to end-stage renal disease (ESRD) before the age of 25 years.

OBSTRUCTIVE UROPATHY

- **Obstructive uropathy** is a term used for obstruction in the urinary passage involving the urethra, bladder, ureters or pelvicalyceal system. It leads to impedance to urine flow and consequent damage to renal function.
- **Nature of obstruction:** It is acute or chronic.
  - **Acute obstruction:** The changes in kidney function are completely reversible after the relief of obstruction.
  - **Chronic obstruction:** It leads to irreversible structural and functional changes.

Site and Cause of Urinary Tract Obstruction

See **Table 10.29.**

TABLE 10.29: Site and cause of urinary tract obstruction.

Site	*Cause*
Infundibular/pelvis	Congenital, calculi, infection, trauma, tumor
Ureteropelvic junction	Congenital stenosis*, calculi, trauma
Ureter	Obstructive megaureter*, ectopic ureter, ureterocele, calculi*, retroperitoneal tumor (lymphoma), inflammatory bowel disease, retroperitoneal fibrosis, chronic granulomatous disease (tuberculosis)
Bladder	Neurogenic dysfunction*, tumor (rhabdomyosarcoma), diverticula, ectopic ureter
Urethra	Posterior urethral valves*, diverticula, strictures, atresia, ectopic ureter, foreign body, phimosis*, priapism prostatic enlargement*, extrinsic compression due to tumor, lymph nodes

*Relatively common.

NEPHROLITHIASIS

- Nephrolithiasis (also known as kidney stones or renal calculi) is a common disorder characterized by the formation of aggregates of microscopic crystals into solid objects (stones).
- **Constituent:** Usually contain calcium or phosphate along with small amounts of proteins and glycoproteins.
- **Size:** They vary greatly in size from millimeters to centimeters.
- **Age and gender:** It usually appears during middle age and is more common in men than women (M:F = 2:1).
- **Risk of recurrence:** Calculi recur in about 50% of cases within 3–5 years.

Etiology (Box 10.21)

Q. Write short note on predisposing factors for renal stones.

- Normal urine contains inhibitors of crystal formation (citrate, inorganic magnesium, pyrophosphate, glycosaminoglycans and nephrocalcin) that prevent the formation of calculi.
- When the chemical concentration of urine is altered, the calculus forming substances may exceed their maximum solubility in water and may favor crystal formation.

Types

Calcium Stones (Oxalate Calculus/Calcium Oxalate)

- Most (80%) renal stones are **composed of calcium complexed with oxalate** (calcium oxalate) or **phosphate** (calcium phosphate) or a mixture of these (calcium oxalate + calcium phosphate). These stones are **radiopaque**.
- Causes (**Box 10.22**).

Uric Acid Stones

- Commonly found in patients **with hyperuricemia** (e.g., gout) and **diseases involving rapid cell turnover** (e.g., leukemias). However, more than 50% of patients have neither hyperuricemia nor increased urinary excretion of uric acid.
- **Uric acid is insoluble in acidic urine** and **urine pH below 5.5 may predispose to uric acid stones.**
- Uric acid stones are **radiolucent** stones.
- Causes (**Box 10.22**).

Struvite Stones or (Triple stones/Magnesium, Ammonium, Phosphate Stones)

- They are composed of calcium phosphate often with magnesium and ammonium phosphate and are **known as struvite stones or triple phosphate stones**.
- Causes (**Box 10.22**): These stones are unique in that they **develop after infections of the urinary tract by urea-splitting bacteria** (e.g., ***Proteus***), which convert urea to ammonia → produces alkaline pH+ slowing of urine flow (people with abnormal urinary drainage, such as those with ureteral reflux, neurogenic bladder, other forms of bladder dysfunction, or ureteral diversions) → precipitation of magnesium, ammonium, phosphate (struvite), and calcium phosphate (apatite).

Cystine Stones

- Cystine stones are uncommon and associated with **cystinuria**, which is due to genetic defects in the renal reabsorption of cystine or other amino acids.
- Stones form at **low urinary pH** (acidic urine)
- Cystine stones also are radiopaque
- Recur frequently in most affected individuals
- Diagnosis is suggested by a positive urine nitroprusside test and confirmed by analysis of the calculus.
- **Urine sediment:** It may show the characteristic **hexagonal cystine crystals** and crystal formation is favored in acidic urine (low pH).

Box 10.21: Predisposing factors for renal stones.

Environmental and dietary factors

- Conditions that favor low volume of urine: High atmospheric temperatures, low intake of fluid
- Diet: High protein, high sodium, low calcium
- High excretion of sodium, oxalate, and urate excretion
- Low excretion of citrate

Acquired causes

- Hypercalcemia
- Ileal disease or resection (increases oxalate absorption and urinary excretion)
- Renal tubular acidosis (RTA) type I (distal)
- Infection: Urinary infection by urea-splitting organisms such as *Proteus, Pseudomonas, Klebsiella, Staphylococcus,* and *Mycoplasma*

Congenital and inherited disorders

- Medullary sponge kidney
- Familial hypercalciuria
- Cystinuria
- Renal tubular acidosis (RTA) type I (distal)
- Primary hyperoxaluria

Box 10.22: Types and causes of renal stones.

1. Calcium oxalate and/or calcium phosphate (~80%)
   - Idiopathic hypercalciuria: Most common
   - Hypercalciuria and hypercalcemia
   - Hyperoxaluria: Enteric (oxalate-containing foods, salt, protein-meat) vitamin C abuse, primary
   - Hyperuricosuria
   - Idiopathic
2. Uric acid (~7%)
   - Associated with hyperuricemia
   - Associated with hyperuricosuria
   - Idiopathic
3. Struvite (magnesium, ammonium, phosphate) ~10%
   - Urinary tract infection
4. Cystine (~2%)
5. Others/unknown (~1%)

Clinical Manifestations

- **Most common** presenting symptoms: (1) **Severe colicky flank and/or abdominal pain** radiating to the anterior abdominal wall and (2) **hematuria** (microscopic or gross). This symptom complex termed renal or ureteric colic. These symptoms are due to partial or full obstruction produced by stones while passing through the ureter.
- **Asymptomatic:** Stone is **incidentally discovered** in an abdominal computed tomography or ultrasound examination for other purposes.

- **Symptoms depending on the site of stone:**
  - **Stones in the renal pelvis usually are painless** unless infection or obstruction is present.
  - **Ureteral stones may cause nausea, vomiting, and severe abdominal** and/or flank pain radiating into the groin, urethra, or genitalia.
  - **Stones at the ureterovesical** junction may produce **dysuria, frequency,** and **urgency**, even in the absence of infection.
  - Once in the bladder, stones are normally passed out without difficulty, but they can remain there and grow to very large sizes in patients with bladder dysfunction.
- Fever and pyuria suggest associated UTI and must be confirmed by urine culture.
- Chronic and complete obstruction can result in hydronephrosis and loss of function in the affected kidney.

Diagnosis/Investigations (Box 10.23)

- **CT-KUB** (CT of kidney, ureter, and bladder) is the **gold standard** for diagnosis. It defines the size and location of any stones (including nonradiopaque stones, such as those containing uric acid and cysteine) in the urinary tract.
- **Abdominal ultrasound or intravenous pyelograms** (IVPs) are generally inferior in sensitivity and specificity compared to the computed tomography scan.
- A **plain X-ray of the abdomen (Fig. 10.20)** has limited diagnostic utility, but may be useful to track progression of previously diagnosed radiopaque stones.
- **Urine analysis:** To confirm the presence of **blood** and check for **evidence of infection**. **Urinary sediment** should be examined under the microscope for crystals. Any stones passed in urine should be saved for analysis. Metabolic evaluation of stones should always be performed before starting on a therapeutic regimen. **Urine culture** should be done when clinically indicated.
- **Laboratory tests:** These include serum studies for renal function, electrolytes, calcium, magnesium, phosphate, and uric acid. If there is hypercalcemia, a PTH level should be obtained.

Box 10.23: Important investigations in patients with renal calculi.

- Routine urine examination (albumin, RBC, WBC, casts and crystals, and pH)
- Renal functions (blood urea, serum creatinine)
- Imaging (ultrasonography and IV urography)
- To find out underlying cause
  - Chemical analysis of calculus passed in urine
  - Plasma calcium, phosphate, and parathormone
  - 24-hour urine for estimation of calcium, oxalate, urate, cysteine

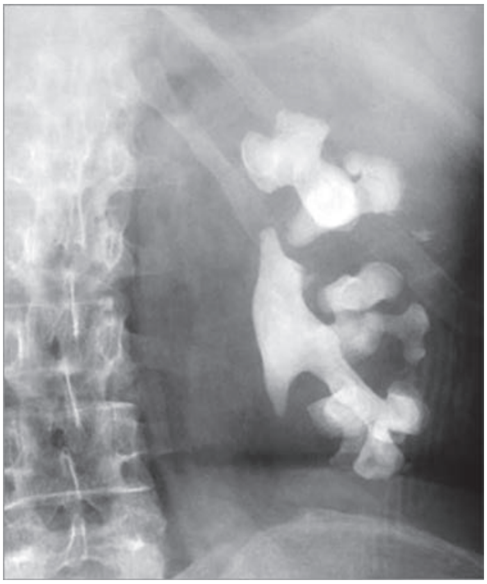

FIG. 10.20: X-ray shows staghorn calculi.

Treatment

Acute Management

- **Acute colic** should be treated with an effective/powerful **analgesic.** Diclofenac orally or IV infusion or as a suppository is very effective. However, opiates may be needed.
- **Increase the water intake** to maintain a daily urine output of 2 L or more. If this is not possible, **intravenous fluids** should be given to **increase urinary output**.
- Stone removal **strategies** are **based on the size of the stone**.
  - Most small calculi (**<5 mm in diameter**) usually **pass spontaneously**.
  - **Alpha blockers** (e.g., tamsulosin) facilitate spontaneous expulsion of distal **ureteral stones of <6 mm size**.
  - **Stones >1 cm diameter** usually need **urological or radiological intervention**. Extracorporeal shock wave lithotripsy (ESWL) causes fragmentation of most of the stones into pieces <5 mm, which then pass spontaneously. Ureteroscopy with a YAG laser (for larger stones) and percutaneous nephrolithotomy also can be used. Open surgery is rarely necessary.
- **Surgical removal** is attempted only if the stone passage becomes complicated. Complicating features include failure to pass stone in 3–7 days, acute renal failure, gross hematuria with clots, or infection. Open surgical procedures are very rarely performed. Endoscopic or surgical removal is recommended for: (a) persistent pain not relieved by analgesia, (b) stone obstructing a single kidney, or bilateral ureteral obstruction and/or pyonephrosis.

Chronic Management

Fluid: Increase the urine volumes (dilution) so that it reduces supersaturation and prevents new stone formation. Increase the fluid intake until daily urine output exceeds 2–3 L.

URINARY TRACT INFECTIONS

Definition

A UTI is associated with multiplication of organisms in the urinary tract and is defined as the presence of more than **10^5 organism/mL** in the midstream sample of urine (MSU).

Clinical Presentation

See **Table 10.30.**

TABLE 10.30: Clinical spectrum of urinary tract infection (UTI).

Asymptomatic bacteriuria (ABU)	***Symptomatic (disease)***
Presence of bacteriuria (>10^5/mL or two occasions in females and on one occasion in males) indicating UTI but without symptoms. ➢ Common in pregnancy ➢ Occurs in the absence of symptoms ➢ Does not usually require ➢ treatment	➢ Includes – Acute urethritis – Acute cystitis – Acute prostatitis – Acute pyelonephritis – Renal abscess – Septicemia with septic shock ➢ Requires antimicrobial therapy

Anatomic Classification of Urinary Tract Infections

- **Lower urinary tract infections:** Include cystitis (bladder), prostatitis, and urethritis.
- **Upper urinary tract infections:** Include infection of kidneys and their collecting systems (pyelonephritis) and perinephric abscess.

Etiology

Q. PE21.1 Enumerate the etiopathogenesis, clinical features, complications and management of urinary tract infection in children.

Q. MI7.3 Describe the etiopathogenesis, clinical features, the appropriate method for specimen collection, and discuss the laboratory diagnosis of urinary tract infections.

Causative organisms: Majority (~85%) of UTI are the caused by **gram-negative bacilli** which are normal inhabitants of the intestinal tract (enteric origin).

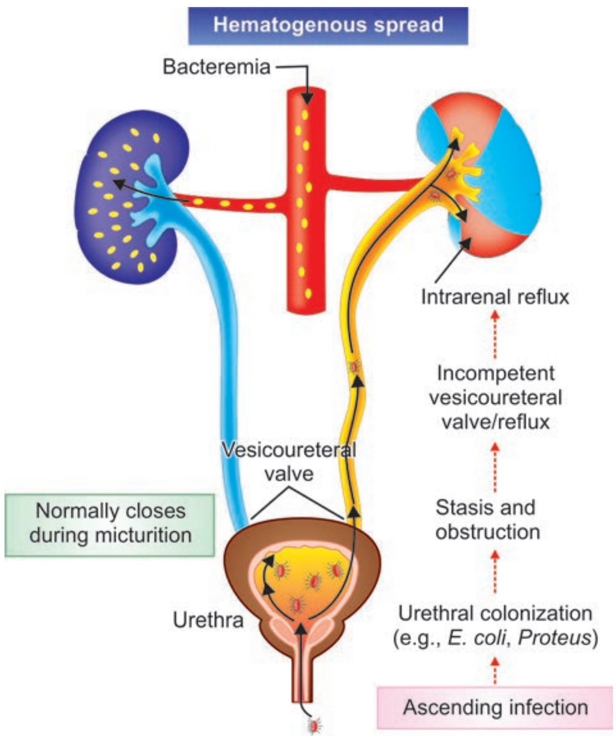
- **Most common pathogens:** *Escherichia coli* (80% cases), *Proteus*, *Klebsiella*, *Enterobacter,* and *Pseudomonas.*
- **Less common:** *Streptococcus faecalis*, staphylococci, and fungi.
- **In immunocompromised patients: Viruses** (polyoma virus, cytomegalovirus, and adenovirus).

Pathogenesis (Fig. 10.21)

Q. Differences between male and female urinary tract infection.

Route of infection: Bacteria can reach urinary tract via the bloodstream, the lymphatics or by direct extension (e.g., from a vesicocolic fistula), but in majority of cases via the ascending transurethral (via the urethra) route.

A. **Ascending infection:** It is the **most common route** of infection of the renal parenchyma, i.e., pyelonephritis. It is a form of endogenous infection, where the source of infecting organisms is the **patient's own fecal flora**. The infection ascends from the lower urinary tract into the renal parenchyma. Different steps in the pathogenesis of pyelonephritis are:
   - ■ **Colonization of the distal urethra and introitus** (in the female): By enteric or coliform bacteria from the perineum due to poor hygiene and hormonal effects.
   - ■ **Entry from the urethra to the bladder**: Organisms may enter the bladder during **urethral catheterization or other instrumentation.** Urinary infections are more common in females, because of:
     - ♦ Shorter urethra (4 cm)
     - ♦ Absence of prostatic fluid which has antibacterial properties
     - ♦ Hormonal changes in women which affect the adherence of bacteria to the mucosa.
     - ♦ Trauma to the urethra during sexual intercourse facilitates entry of introital bacteria into the bladder.
     - ♦ Gram-negative enteric organisms residing around the anal region also colonize the periurethral region.
   - ■ **Urinary tract obstruction and stasis of urine.**



Hematogenous spread
Bacteremia
Intrarenal reflux
Incompetent vesicoureteral valve/reflux
Vesicoureteral valve
Normally closes during micturition
Stasis and obstruction
Urethra
Urethral colonization (e.g., *E. coli*, *Proteus*)
Ascending infection

FIG. 10.21: Pathogenesis of acute pyelonephritis. More common mode is ascending infection. Hematogenous infection results from bacteremic spread.

Q. Write short note on causes of urinary tract infection in male.

- **Obstruction/bladder dysfunction:** Causes incomplete emptying and increased residual volume of urine. Examples: benign prostatic hypertrophy, tumors, strictures, or calculi.
- **Neurogenic bladder dysfunction:** Diabetes, spinal cord injury, tabes dorsalis, and multiple sclerosis predisposes to UTI.
- **Stasis:** Organisms introduced into the bladder can multiply when there is stasis.

B. **Hematogenous route:** It is less common route of infection. Because of rich blood supply, bacteria can seed the kidneys during the course of septicemia or infective endocarditis through the bloodstream. It occurs with nonenteric organisms (e.g., staphylococci), fungi, and viruses. Hematogenous infections occur in: (i) the presence of ureteral obstruction, (ii) debilitated patients, and (iii) patients receiving immunosuppressive therapy.

Clinical Features (Table 10.31)

Q. List the differences between complicated and uncomplicated UTI.

TABLE 10.31: Clinical features of UTI.

➢ Fever with chills and rigors	➢ Suprapubic pain and tenderness resulting from cystitis
➢ Micturition abnormalities – Increased frequency of micturition – Dysuria (painful voiding) or scalding micturition – Urgency – Strangury: Intense desire to pass more urine after the bladder has been emptied. It is due to detrusor spasm and occurs in cystitis.	➢ Urine: – Hematuria – Cloudy urine with an unpleasant odor

Uncomplicated versus Complicated UTI (Table 10.32)

TABLE 10.32: Differences between uncomplicated versus complicated urinary tract infection (UTI).

Features	*Uncomplicated urinary tract infection*	*Complicated urinary tract infection*
Characteristics	UTI occurring in patients with functionally normal urinary tracts	UTI occurring in patients with abnormal urinary tracts (e.g., with stones, or associated diseases such as diabetes mellitus) or infection that extends beyond the bladder
Lesions	Includes cystitis or urethritis due to bacterial colonization of the bladder or urethra	Infection of renal parenchyma and renal pelvis (pyelonephritis) or prostate (prostatitis)
Sex affected	Much more in females than in males	Infection in men often considered complicated
Predisposing factors	May not be obvious	Usually occurs in presence of obstructive lesions or following instrumentation on urinary tract
Clinical features	Burning on urination and frequent urination without fever or flank pain	Accompanied by fever or flank pain ➢ Costovertebral angle tenderness ➢ Pelvic or perineal pain in men (prostatitis)
Prognosis	Responds well to treatment and persistent or recurrent infection seldom results in serious kidney damage	May be difficult to treat and relapses after treatment are common
Sequelae	Rare	Common such as sepsis, metastatic abscesses, and renal failure

Acute urethral syndrome: About one-third of females with dysuria and pregnancy have either insignificant bacteria in midstream culture or completely sterile cultures and is known as acute urethral syndrome. It is often due to infection with usual organisms (culture shows only 10^2–10^4 bacteria) or due to unusual organism (*Neisseria gonorrhoeae, Chlamydia trachomatis*).

Causes of Dysuria (Box 10.24)

Box 10.24: Causes of dysuria.

- Urinary tract infections (e.g., urethritis, cystitis, vaginitis, pyelonephritis)
- Sexually transmitted infections
- Genital herpes
- Chlamydia
- Gonorrhea
- Inflammation and irritation of bladder and urethra, e.g., stones

Factors Determining Symptomatic Infection

- *Virulence:* Ability of the organism to adhere to epithelial cells determines the degree of virulence.
- *Innate host defense:* The following hosts defense mechanisms are required for the prevention of UTI:
  - *Neutrophils:* Activation of neutrophils is necessary for bacterial killing and their impaired function predisposes an individual to severe UTI.
  - *Complement:* Complement activation with IgA production by uroepithelium (acquired immunity) plays a major role in defense against UTI.

  - *Commensal organisms* (e.g., lactobacilli)*: Form* part of the normal host defense and their eradication by spermicidal jelly or disruption by certain antibiotics results in overgrowth of *E. coli.*
  - *Urine flow* and normal micturition: Wash out bacteria and stasis of urine predisposes to UTI.
  - *Uroepithelium*—mannosylated proteins: Such as Tamm–Horsfall proteins (THPs), have antibacterial properties and are present in the mucus and glycocalyx covering uroepithelium. Normally, they interfere with bacterial binding to uroepithelium. Thus, disruption of this uroepithelium by trauma (e.g., sexual intercourse or catheterization) predisposes to UTI.
- Pregnancy is associated with an increased incidence of UTI. Factors that favor UTI include: (1) decreased ureteral tone (progestational activity), (2) decreased ureteral peristalsis, and (3) transient incompetence of the vesicoureteral valves.

Honeymoon Cystitis (or "Honeymoon Disease")

Q. Write short note on honeymoon cystitis.

Honeymoon cystitis is caused as a result of frequent or prolonged sexual activity, as would typically be expected in the honeymoon period of a marriage. It can occur when a woman has sex for the first time, or when a woman has sex after a long period of time without any sexual activity.

Symptoms: Same as with cystitis due to other cause. During sex, *E. coli* on the skin around your anus can be transferred to urethra of women (for example, via partner's fingers or penis).

Investigations

Urine Examination

- **Dipstick tests:** Most gram-negative organisms reduce nitrates to nitrites and dipstick tests (nitrite test) are used to detect nitrite in urine. Dipsticks that detect significant pyuria depend on the release of esterases from leukocyte (leukocyte esterase test). Positive dipstick tests for both nitrite and leukocyte esterase are highly predictive of acute infection.
- **Microscopic examination:** For leukocytes, leukocyte casts and red cells.
- **Culture and sensitivity** of a freshly voided clean-catch midstream specimen of urine.

Box 10.25 lists causes of sterile pyuria.

Special Investigations

- Prostatitis
  - Per rectal examination of the prostate
  - Prostatic massage followed by urine culture

Factors that indicate a complicated UTI

- **A**natomical abnormality of the urinary tract
- **B**acterial persistence in spite of adequate therapy
- **C**hildhood UTI
- **D**iabetes
- **E**lderly
- **F**unctional abnormality of the urinary tract [vesicoureteric reflux (VUR); neurogenic dysfunction]
- **G**estational (pregnancy); **G**ender-male
- **H**ospital acquired (catheter induced, instrumentation, stents)
- **I**mmunosuppression

Symptoms and Signs of UTI

Constitutional:

- Malaise
- Listlessness
- Fever
- Chills
- Nausea and vomiting

Upper tract—symptoms	**Upper tract—signs**
Flank pain	Flank/CVA tenderness
Back ache	Flank mass
Heaviness in the flank	Scoliosis
	Psoas spasm

Lower tract—symptoms	**Lower tract—signs**
Frequency	Suprapubic tenderness
Scalding urination	Bladder distension (bladder outlet obstruction)
Urgency	Urethral discharge
Strangury	Urethral tenderness
Hematuria	
Turbid urine (pyuria)	
Foul smelling urine	
Pneumaturia/fecaluria	

Genital-female—symptoms	**Genital-female—signs**
Leukorrhea	Vaginal discharge
Dyspareunia	Pelvic organ prolapse

	Prostatic enlargement on DRE

(CVA: Costovertebral angle; DRE: Digital rectal examination)

Box 10.25: Causes of sterile pyuria.

- Partially treated UTI
- Tuberculosis of urinary tract
- Calculi in urinary tract
- Infection with other organisms (e.g., *Chlamydia, Corynebacterium*, etc.)
- Tumors of bladder
- Chemical cystitis/drugs
- Prostatitis
- Interstitial nephritis
- Appendicitis

- Cystitis: Cystoscopy.
- **Renal ultrasonography CT-KUB, MR urogram:** To identify obstruction, cysts, and calculi.
- **Intravenous urography (IVU),** including a postvoid film of bladder: To identify physiological and/anatomical abnormalities of urinary tract.
- Dimercaptosuccinic acid (DMSA) renal scan: For pyelonephritis.
- Micturating cystourethrogram (**MCU**) to identify vesicoureteric reflux and disturbed bladder emptying.
- In females with recurrent UTI, **pelvic examination** to exclude cystocele, rectocele, and uterine prolapse.

Treatment

- **Antibiotic therapy:** The choice of antibiotic depends on the result of urine culture and sensitivity of urine.
  - The commonly employed antibiotics include cotrimoxazole (trimethoprim and sulfamethoxazole 1 double strength tablet two times daily), ampicillin (250 mg three times daily), amoxicillin (250 mg 8-hourly three times daily), oral cephalosporin, nitrofurantoin (50 mg three times daily), and quinolones. Treatment is over 3–5 days in uncomplicated infections (nitrofurantoin for 7 days) and for 7–10 days in complicated infections.
- **Hospitalized patients:**
  - No risk factors for infection with a multidrug-resistant organism → ceftriaxone (1 g IV once daily) or piperacillin-tazobactam (3.375 g IV every 6 hours)
  - At least one risk factor for infection with a multidrug-resistant organism → antipseudomonal carbapenem (imipenem 500 mg IV every 6 hours, meropenem 1 g IV every 8 hours, or doripenem 500 mg IV every 8 hours).
  - *Enterococcus* species or MRSA are suspected → add vancomycin, daptomycin, or linezolid.
  - "Single-shot" treatment with 3 g of amoxicillin or 1.92 g of cotrimoxazole can be used in patients with bladder symptoms of less than 36 hours duration and without any previous history of UTI.
  - If patients has a calculi, catheter or other obstructions, no antibiotic is necessary unless symptomatic.
- **Fluid intake:** A high (2 L daily) fluid intake during treatment and for some subsequent weeks to initiate water diuresis, so as to maintain a high rate of urine flow.
- **Other measures:**
  - Regular complete emptying of urinary bladder at 2- to 3-hour intervals.
  - Alkalinization of urine
  - Urinary analgesics (e.g., phenazopyridine) and antispasmodics (e.g., hyoscyamine) to be given for detrusor spasm.
  - If patients presents for the first time with high fever, loin pain and tenderness, urgent renal ultrasound examination is performed to exclude an obstructed pyonephrosis. If this is present percutaneous nephrostomy is performed to drain it.
  - Cranberry juice inhibits adherence of uropathogens to uroepithelial cells, hence advisable to prevent recurrent UTI.
  - In females: The incidence of UTIs can be reduced by (1) adequate perineal hygiene, (2) emptying the bladder before bedtime and before and after intercourse, and (3) application of 0.5% cetrimide cream to periurethral area before intercourse. Atrophic vaginitis should be identified and treated in postmenopausal women.
  - Avoidance of constipation (may impair bladder emptying).

Asymptomatic bacteriuria: It requires treatment (1) if a patient is pregnant, (2) in case of renal transplantation, or (3) before planning for a urologic surgery. Treatment of asymptomatic bacteriuria in pregnant women decreases the occurrence of pyelonephritis.

ACUTE PYELONEPHRITIS

Q. Discuss the etiology, clinical features, investigations, diagnosis, and management of acute pyelonephritis.

Q. Write short essay/note on common causes, diagnostic features, and management of upper urinary tract infections.

Definition: Acute pyelonephritis is an acute suppurative inflammation of upper urinary tract affecting the tubules, interstitium, and renal pelvis. There is often coincident cystitis.

Clinical Features

Classic triad: (1) loin pain, (2) fever, and (3) tenderness over the kidneys. Presence of this triad and significant bacteriuria usually indicates acute pyelonephritis.

- Sudden onset of pain in one or both loins (costovertebral/renal angle), radiating to the iliac fossa and suprapubic area.
- Fever with chills and rigors, and malaise
- **Tenderness in the renal angle**
- Dysuria, frequency, and urgency. Frequent passage of small amount of urine accompanied by scalding, cloudy urine.
- Acute pyelonephritis caused by the presence of obstruction (e.g., stone, tumor, bladder neck obstruction, enlarged prostate), can be very severe and may progress to renal abscess.

- Rarely, acute pyelonephritis may be associated with necrotizing papillitis/papillary necrosis. Causes include diabetes mellitus, chronic urinary obstruction, analgesic nephropathy, and sickle-cell disease.

Investigations

Q. Write short note on urinary abnormalities in acute pyelonephritis.

- **Peripheral blood:** Characteristically shows leukocytosis.
- **Urine examination**
  - **Microscopy** shows numerous pus cells and organisms, WBC casts, some red cells, and epithelial cells.
  - **Culture** of midstream urine (MSU) shows growth the causative organism.
- **Other investigations:** When the diagnosis is uncertain, other investigation are required to exclude anatomical abnormalities of the urinary tract. When acute pyelonephritis is severe, the possibility of any obstruction or abscess formation must be excluded. It is also necessary, if there is inadequate response or rapid recurrence of pyelonephritis following appropriate therapy.
  - **Ultrasonography:** Most frequently done, but is relatively insensitive.
  - **Computerized tomography (CT)** is performed if ultrasound is normal. It can detect calculi, obstruction, hemorrhage, gas, enlargement of kidney, and inflammatory masses (damaging renal function).
  - **Intravenous urography** is usually not done at present.
  - **Radionuclide scan:** The radionuclide agent is injected into bladder through suprapubic route may be useful to detect reflux.
  - **Dimercaptosuccinic acid renal scan:** If performed within 2 days DMSA can help diagnosing acute pyelonephritis. It is advisable to scan after 4–6 months of an acute episode to detect renal parenchymal damage.

Management

Intravenous antibiotics: Intravenous ampicillin, amoxicillin plus aminoglycosides (e.g., tobramycin), cephalosporin (e.g., cefuroxime), quinolone (e.g., ciprofloxacin), or a combination beta-lactam/beta-lactamase inhibitor (piperacillin-tazobactam) or carbapenem (meropenem) (discussed above).

Persistent or Recurrent UTI

Q. Write short essay/note on persistent or recurrent urinary tract infection and its management.

- In some patients with UTI, the causative organism persists on repeat culture of urine in spite of treatment, or reinfection develops with any organism after an interval. Such cases, there is more probably an underlying cause is present and hence a more detailed investigation is necessary.
- Recurrent infections are common in females.
- Recurrent UTI, especially in the presence of an underlying cause may produce permanent renal damage. If an underlying cause cannot be treated, suppressive antibiotic therapy can prevent recurrence and reduce the risk of septicemia and renal damage.
- Culture and sensitivity of urine should be at regular intervals.

Treatment: Two or three antibiotics in sequence, rotating every 6 months often reduces the emergence of resistant organisms. Other methods discussed above.

Emphysematous Pyelonephritis

Q. Write short note on emphysematous pyelonephritis.

- It is a type of severe acute pyelonephritis most often caused by *E. coli* and *Klebsiella pneumoniae*.
- The major risk factors for emphysematous UTIs are diabetes and urinary tract obstruction.
- The infections primarily occur in women at a mean age of about 60 years.
- Abdominal pain is the major clinical manifestation with renal angle tenderness. Pneumaturia may be seen after bladder catheterization.
- The diagnosis of emphysematous UTIs is made by abdominal imaging; computed tomography is more sensitive than plain films and can detect obstructing lesions.

Treatment: Parenteral antibiotics, percutaneous drainage/nephrectomy.

CHRONIC PYELONEPHRITIS

Q. Write short essay on the clinical features, investigations, and management of chronic pyelonephritis (reflux nephropathy).

Chronic pyelonephritis is a chronic inflammation of tubulointerstitial tissue leading to scarring of calyces, pelvis, and renal parenchyma.

Types

- **Reflux nephropathy (chronic reflux-associated pyelonephritis/atrophic pyelonephritis):** It results recurrent UTIs from a combination of factors such as:
    - **Congenital vesicoureteral reflux and intrarenal reflux:** Chronic pyelonephritis is so often associated with vesicoureteric reflux and some feel that it is better named "reflux nephropathy." Reflux may be unilateral or bilateral and accordingly causes scarring of one or both the kidney.
    - **Superimposition of a urinary** infection acquired in infancy or early childhood.
- **Chronic obstructive pyelonephritis:** Develops due to **recurrent infections** superimposed on obstructive lesions, which lead to renal inflammation parenchymal atrophy, and scarring.

Chronic pyelonephritis is an important cause of renal damage and ESRD. Morphological changes are depicted in **Figure 10.22**.

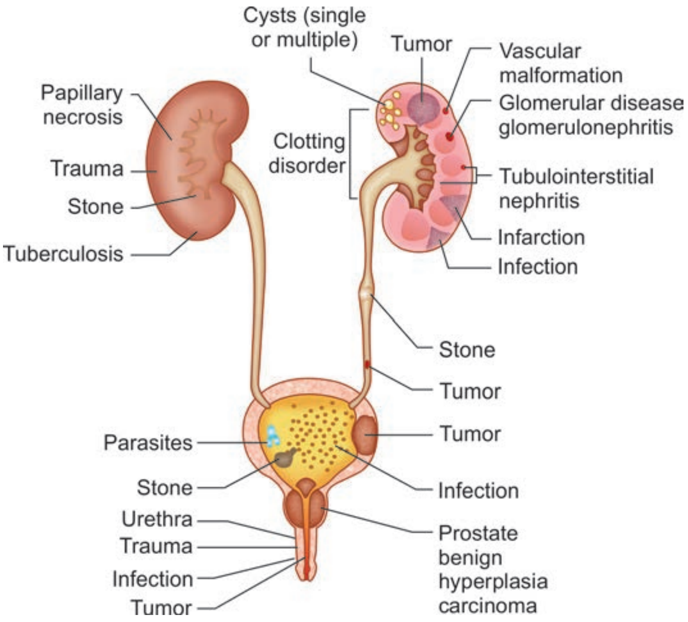

FIG. 10.22: Morphological changes in reflux nephropathy compared with normal.

Clinical Features

- Reflux pyelonephritis may be of silent onset. Clinical features includes back pain, lassitude, or symptoms of uremia or hypertension. Other symptoms include frequency of micturition, dysuria, pyuria, and bacteriuria.
- **Xanthogranulomatous pyelonephritis (XGP):** Predominantly affects elderly women. The condition is commonly associated with renal calculi or obstructive uropathy and is usually unilateral. The kidney is enlarged, and nonfunctioning and may even mimic a tumor.

Investigations

- **Culture of the urine:** *E. coli* is the most common organism causing infection. Other organisms include *Proteus, Pseudomonas aeruginosa,* and staphylococci.
- **Ultrasound of kidneys**
- **CT scan of the kidneys:** Diagnostically, it reveals irregular renal outlines, clubbed calyces, and a variable decrease in the size of kidney. The condition may be unilateral or bilateral and may affect entire or part of the kidney.
- DMSA scan is more accurate than IVU.
- **Intravenous urogram:** Shows localized contraction of the renal substance associated with clubbing of the adjacent calyces.
- **Micturating cystourethrogram (MCU):** Reveals vesicoureteric reflux, but has been replaced by radionuclide cystography scan.
- **Cystoscopy and urography:** May detect any abnormality causing obstruction to the flow of urine.

Management

- Eradicating predisposing factors:
    - Examples include treatment of calculi and malformations.
    - Surgery is performed if the vesicoureteric reflux persists and is indicated only when the disease is confined to one kidney. Most cases of childhood reflux likely to disappear spontaneously. Patients with end-stage renal failure require renal replacement.
- Treatment of infection: Meticulous early detection and control of infection can prevent further scarring and allow normal growth of the kidneys. Unfortunately, once the parenchyma is scarred it becomes susceptible to blood–borne reinfection sometimes with a different and resistant organism. Thus, antibiotics may be of temporary benefit and progressive renal damage is common.
    - Use of appropriate antibiotics for 7 days.
    - If the infection cannot be eradicated suppressive therapy may be given several months with trimethoprim (100 mg at bed time) or nitrofurantoin (50 mg at bed time).
- Other measures:
    - Complete emptying of the bladder should be advised.
    - Double micturition is advised if reflux. This consists of emptying of the bladder and then again second time attempt to empty the bladder, after about 10–15 minutes.
- Control of hypertension because severe hypertension is a relatively common cause of end-stage renal failure in childhood or adult life.

TUBERCULOSIS OF THE URINARY TRACT

Q. Describe renal tuberculosis.

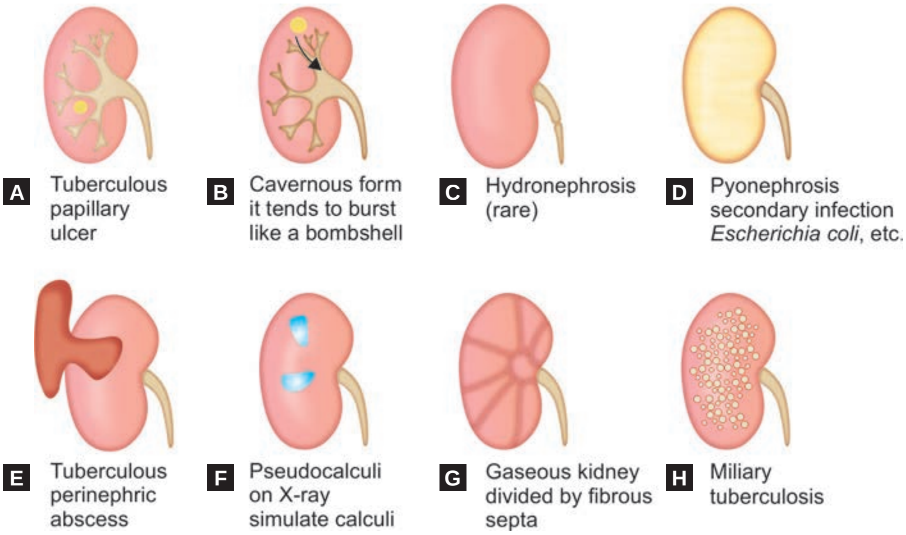
Q. Briefly outline the clinical features, investigations, and treatment of tuberculosis of the urinary tract.

Tuberculosis of the urinary tract results from hematogenous spread from a distant primary focus of infection that is often impossible to identify.

Types of lesions in renal tuberculosis (**Figs. 10.23A to H** and **Table 10.33**).

TABLE 10.33: Types of lesions in renal tuberculosis.

Tuberculous papillary ulcer	Tuberculous perinephric abscess
Cavernous form	Pseudocalculi
Hydronephrosis	Caseous (putty) kidney
Pyonephrosis	Miliary



A Tuberculous papillary ulcer
B Cavernous form it tends to burst like a bombshell
C Hydronephrosis (rare)
D Pyonephrosis secondary infection *Escherichia coli*, etc.
E Tuberculous perinephric abscess
F Pseudocalculi on X-ray simulate calculi
G Gaseous kidney divided by fibrous septa
H Miliary tuberculosis

FIGS. 10.23A TO H: Various types of lesions in tuberculosis of kidney.

Etiology and Pathology

- Tuberculosis usually involves one kidney. Rarely, tuberculosis may be bilateral as part of the generalized process of miliary tuberculosis.
- Tuberculous granulomas in the region of renal pyramid may coalesce to form an ulcer and discharge mycobacteria and pus cells into the urine.
- Untreated lesions of renal tuberculosis may enlarge and form tuberculous abscess in the parenchyma.
- Fibrosis at the necks of the calyces and the renal pelvis may cause tuberculous pyonephrosis.
- Extension of tuberculous pyonephrosis or renal abscess may result in perinephric abscess and the kidney may be progressively replaced by caseous material (putty kidney). This may become calcified (cement kidney).
- Renal tuberculosis is often followed by infection of the ureters and bladder leading to ureteral stricture and contraction of bladder.
- Rarely, cold abscesses may form in the loin. In male, tuberculous epididymo-orchitis may develop even without any lesion in bladder.

Clinical Features

- Usually occurs between 20 and 40 years of age
- Affects males more commonly than females (2:1)
- Affects right kidney more commonly than the left

Symptoms

These include a dull ache in the renal angle, increased frequency of micturition, dysuria, and constitutional symptoms such as fever (evening rise of temperature) malaise and weight loss. Tuberculous cystitis present with hematuria and painful micturition.

- **Physical examination:** Shows an enlarged palpable kidney and tenderness in the renal angle.

Investigation

- **Urine examination:**
  - **Microscopic examination: Sterile pyuria** is characterized by urine containing pus cells, but fails to grow any organism on routine culture. This is the **characteristic feature**.
  - **Urine examination for tubercle bacilli:** Five early morning consecutive samples of urine should be examined (because there is usually intermittent excretion of tubercle bacilli). Alternatively, a 24-hour urine collection can be examined for acid-fast bacillus (AFB).
  - **Culture of the urine:** Diagnosis of active tuberculous infection depends on culture of mycobacteria from early-morning urine samples.
- **Radiography**
  - **Plain KUB radiograph:** It may show calcification (pseudocalculi) in the renal parenchyma and ureter.
  - **Chest X-ray:** Should be done in all cases to exclude active or previous evidence of pulmonary tuberculosis.
- **IVU:** May reveal irregular contour of the kidney, hydrocalyx, cold abscess, displacement of adjacent calyces, and small contracted bladder (systolic or thimble bladder).
- **Ultrasonography:** May show dilated calyces, hydronephrosis, small abscesses, and areas of calcification.
- **Excretion urography:** May show cavitating lesions in the renal papillary areas with calcification. May also show ureteral obstruction with hydronephrosis.
- **Cystoscopy:** May show a characteristic "golf hole" appearance of the ureteric orifice due to sclerosing periureteritis.

Treatment

- **Antituberculous chemotherapy:** Similar to that for pulmonary tuberculosis. Renal ultrasonography or excretion urography should be done 2–3 months after initiation of treatment as ureteric strictures may first develop in the healing phase.
- Surgical treatment may be required in selected cases.

RENAL REPLACEMENT THERAPIES

Q. Write short essay/note on renal replacement therapy.

Requirement

Renal replacement therapy (RRT) may be required on a temporary measure in patients with AKI or on a permanent measure for CKD.

Main options of renal replacement therapy (Box 10.26, Table 10.34 and **Fig. 10.24):** (1) Peritoneal dialysis, (2) intermittent hemodialysis (HD) combined with ultrafiltration, if necessary, (3) intermittent hemofiltration, (4) continuous arteriovenous or venovenous hemofiltration, and (5) hemodiafiltration, and (6) renal transplantation.

Box 10.26: Aim of renal replacement techniques.

- To replace all the excretory functions of the normal kidney namely excretion of nitrogenous wastes
- Maintenance of:
  - Plasma biochemistry
  - Normal electrolyte concentrations
  - Normal extracellular volume (fluid balance)

Note: They do not replace the endocrine and metabolic functions of the kidney.

TABLE 10.34: Options of renal replacement therapy.

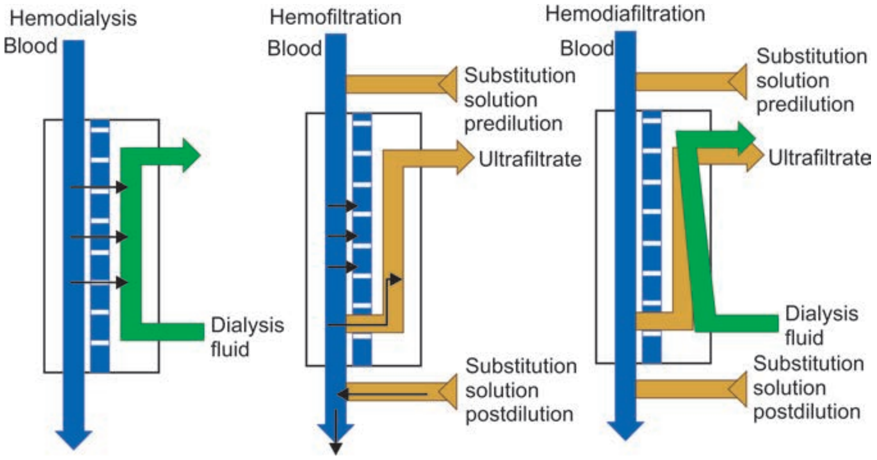
Dialysis ➢ Hemodialysis ➢ Peritoneal dialysis	➢ Clearance of small molecules and toxins using diffusion occurring across a membrane. ➢ Dialysis with clearance occurring across a synthetic membrane. ➢ Dialysis with clearance occurring across a native peritoneal membrane.
Ultrafiltration	Fluid removal across a semipermeable membrane during dialysis by convection (solutes are moved under pressure across a membrane)
Hemofiltration	Continuous dialysis therapy which involves removal of plasma water and its dissolved constituents (e.g., K^+, Na^+, urea, phosphate) by convection flow across a high-flux semipermeable membrane, and concurrent reinfusion of an electrolytic solution of the desired biochemical composition
Hemodiafiltration	Combination of hemodialysis and hemofiltration
Continuous renal replacement therapies	Include hemofiltration and hemodiafiltration

Hemodialysis

Q. Write short note on hemodialysis.

Q. Describe the types and indications for dialysis. Enumerate complications of hemodialysis.

Hemodialysis **(Fig. 10.25)** is the most common form of RRT used in ESRD and also in AKI.



Hemodialysis
Blood
Dialysis fluid
Hemofiltration

Semipermeable membrane
Blood return (to patient)
Dialysate return
Negative pressure
Dialysate inflow

FIG. 10.26: Hemodialysis showing changes across a semipermeable dialysis membrane.

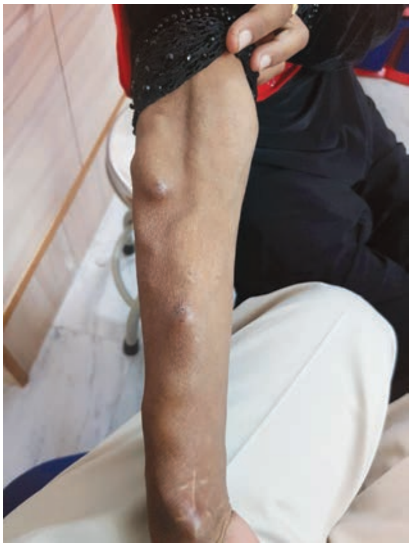

FIG. 10.27: Arteriovenous fistula (AV) created for dialysis.

Basic Principles

- In hemodialysis, blood from the patient is pumped through an array of semipermeable membranes (the dialyzer, often called an "artificial kidney").
- This brings the blood into close contact with dialysate (dialysis fluid) flowing countercurrent to the blood on the other side of membrane.
- This allows accumulated uremic toxins (e.g., urea and creatinine) and electrolytes (e.g., potassium) to diffuse across a semipermeable membrane **(Fig. 10.26)** from the blood (where they are in high concentrations), to the dialysis fluid on the other side (where they are in low concentrations). This in turn results in changes in the plasma biochemistry toward that of the dialysate due to the diffusion of molecules down their concentration gradients.

Access for Hemodialysis

Usually for adequate dialysis, required blood flow is 200–300 mL/minute and the dialysate flow is 500 mL/minute. Hemodialysis involves gaining access to the circulation through:

- **Arteriovenous fistula (Fig. 10.27):** For long-term dialysis access to the bloodstream is achieved by surgical construction of an arteriovenous fistula, usually in the forearm using the radial or brachial artery and the cephalic vein.
- **Arteriovenous graft :** In patients with poor-quality veins or arterial disease (e.g., diabetes mellitus) access is obtained by interposing a piece of synthetic material [polytetrafluoroethylene (PTFE) grafts] between native artery and native vein.
- **Central venous catheter:** If immediate dialysis is required, a large bore double lumen cannula may be inserted into a central vein (subclavian, jugular or femoral).

Each session of hemodialysis usually lasts for 4–5 hours. Two or three sittings/week may be required. Indications of RRT discussed under AKI.

Types of hemodialysis are depicted in **Figure 10.28**.

Complications

Q. Write short essay/note on complications of hemodialysis.

- **Hypotension during dialysis:** It is the major complication and its contributing factors include: (1) excessive removal of extracellular fluid and hypervolemia, (2) shift of fluid into intracellular compartment (due to rapid reduction in urea in the extracellular compartment) and inadequate "refilling" of the blood compartment from the interstitial compartment, (3) abnormalities of venous tone, (4) autonomic neuropathy, (5) acetate toxicity that causes vasodilatation, and (6) left ventricular failure.
- **Other complications:**
  - Cardiac arrhythmias due to potassium and acid-base shifts
  - Hemorrhage due to anticoagulants and venous needle discontinuation
  - Air embolism due to disconnected or defect lines and equipment malfunction
  - Anaphylactic reactions to the dialyzer may rarely occur to ethylene oxide (used to sterilize most dialyzers) or in patients receiving ACE inhibitors (with polyacrylonitrile dialyzers).
  - Hard-water syndrome due to failure to soften water resulting in a high calcium concentration prior to mixing with dialysate concentrate.
  - Hemolytic reactions
  - Infections usually occur with vascular access devices (catheter or fistula).
  - Pulmonary edema due to fluid overload. Other features include hypothermia, platelet consumption, and electrolyte disturbances.
- **Dialysis disequilibrium syndrome:** May develop following a dialysis session. It is characterized by nausea, vomiting, restlessness, headache, hypertension, myoclonic jerks, and in severe cases, seizures and coma. This is because of rapid changes in plasma osmolality leading to cerebral edema.
- **Dialysis dementia:** May develop in patients on long-term hemodialysis. It is characterized by speech dyspraxia, myoclonic jerks, dementia, seizures and later, death. It is mainly due to aluminum toxicity and some may be due to viral infection.

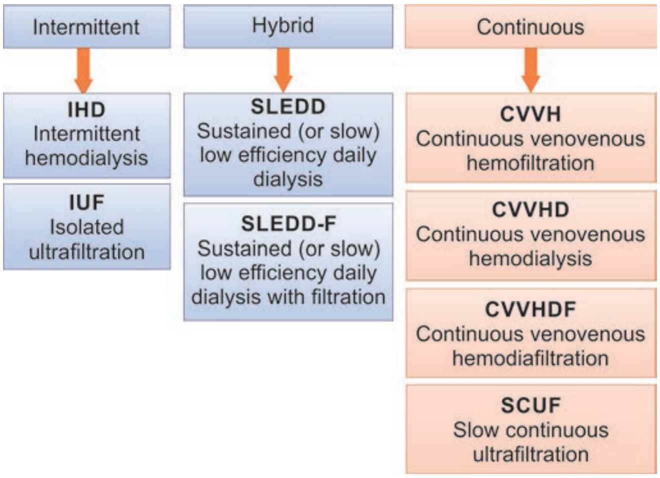
The rate of death from cardiac disease is higher in patients on hemodialysis when compared to patients on peritoneal dialysis or after renal transplantation.

Acute Dialysis in Critically Ill Patients

Continuous Renal Replacement Therapy

Advantages

- It is used in critically ill patients who cannot tolerate large fluid shifts and hypotension that frequently occurs during standard hemodialysis.
- It allows slow and isotonic fluid removal. Thus produces excellent hemodynamic tolerance, even in patients with shock or severe fluid overload.
- Since dialysis is continuous, volume removal and correction of metabolic abnormalities can be modified at any time. This allows rapid adjustment in critically ill patients.



Intermittent
Hybrid
Continuous
IHD
Intermittent hemodialysis
IUF
Isolated ultrafiltration
SLEDD
Sustained (or slow) low efficiency daily dialysis
SLEDD-F
Sustained (or slow) low efficiency daily dialysis with filtration
CVVH
Continuous venovenous hemofiltration
CVVHD
Continuous venovenous hemodialysis
CVVHDF
Continuous venovenous hemodiafiltration
SCUF
Slow continuous ultrafiltration

FIG. 10.28: Types of hemodialysis.

Continuous renal replacement therapy modalities

The most common is continuous venovenous hemodiafiltration. This combines convective and diffusive clearance through a dialyzer with reinfusion of electrolyte-rich solutions.

Indications

Continuous renal replacement therapy (CRRT) is of choice in patients with ARF combined with hemodynamic instability, cerebral edema, severe fluid overload, and encephalopathy.

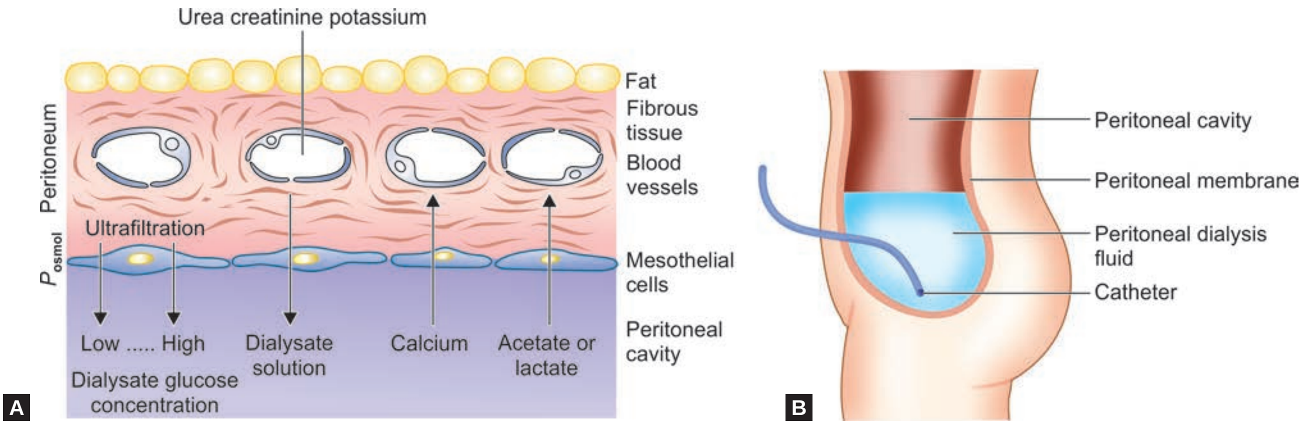
Complications

Embolization, arteriovenous fistula formation, hemorrhage, and infection from catheter access.

Peritoneal Dialysis

Q. Write a short note on peritoneal dialysis and its indications (Box 10.27).

- In peritoneal dialysis, the **peritoneal membrane of the patient acts as a semipermeable membrane**. Through this diffusion of water and solutes takes place and this avoids the need of extracorporeal circulation of blood.



Urea creatinine potassium
Peritoneum
Fat
Fibrous tissue
Blood vessels

B
Peritoneal cavity
Peritoneal membrane
Peritoneal dialysis fluid
Catheter

FIGS. 10.29A AND B: (A) Principle of peritoneal dialysis; (B) Peritoneal dialysis.

- **Very simple, low-technology** treatment when compared to hemodialysis.
- **Principle (Fig. 10.29A):** Solutes diffuse from blood across the peritoneal membrane to peritoneal dialysis fluid down a concentration gradient and water diffuses through osmosis.

Box 10.27: Indications for peritoneal dialysis.

- Preferred mode of dialysis for infants and young children
- Patients with severe hemodynamic instability on hemodialysis
- Patients with difficult vascular access
- Patients with heart failure
- Patient choice

Procedure

- A plastic or silicone tube/catheter is placed into the peritoneal cavity through the anterior abdominal wall (**Fig. 10.29B**).
- Dialysate is instilled into the peritoneal cavity, usually under gravity.
- Urea, creatinine, phosphate, and other uremic toxins pass across the peritoneal membrane into the dialysate because of their concentration gradients.
- Water (with solutes) is attracted into the peritoneal cavity by osmosis.
- Dextrose in the peritoneal dialysis fluid acts as osmotic agent
- The fluid is removed by gravity after 30–60 minutes, and the fluid is changed regularly to repeat the process several times. This is called intermittent peritoneal dialysis and is mainly used in ARF.

When chronic peritoneal dialysis required, a soft catheter is inserted, with its tip in the pelvis with an exit site in the lateral abdominal wall.

Complications

- **Technical complications:** Catheter-related exit site infection, tunnel infection, peritonitis, pericatheter leakage, poor drainage, catheter migration rarely bowel perforation.
- **Raised intra-abdominal pressure:** Hernias, fluid leaks, rectal prolapse, vaginal prolapse, low back pain, scrotal edema, and decrease in appetite, **sclerosing encapsulating peritonitis**.

Forms of Peritoneal Dialysis

- **Continuous ambulatory peritoneal dialysis:**
  - In this type of peritoneal dialysis, dialysate is present within the peritoneal cavity continuously, except when dialysate is being exchanged.
  - Dialysate exchanges are performed 3–5 times a day.
  - About 1.5–3 L bags of dialysate are infused into the peritoneal catheter using a sterile no-touch technique.
  - Each exchange takes 20–40 minutes.
  - This technique is useful for maintenance of peritoneal dialysis in patients with end-stage renal failure (CRF).
- **Nightly intermittent peritoneal dialysis (NIPD):**
  - In this type of peritoneal dialysis, an automated device is used to perform exchanges each night (while the patient is asleep).
  - Apart from that night, sometimes dialysate is left in the peritoneal cavity during the day, to increase the time during which biochemical exchange is occurring.

- **Tidal dialysis:** In this type of peritoneal dialysis, a residual volume of dialysate is left within the peritoneal cavity with continuous cycling of smaller volumes in and out.

Differences between hemodialysis and peritoneal dialysis are presented in **Table 10.35**.

TABLE 10.35: Differences between hemodialysis and peritoneal dialysis.

Features	*Hemodialysis*	*Peritoneal dialysis*
Efficiency	Efficient	Less efficient
Duration and time interval	4 hours three times per week is usually adequate	Four exchanges per day are usually required. Each taking 4-6 hours (continuous ambulatory peritoneal dialysis) or 8–10 hours each night (automated peritoneal dialysis)
Interval between dialysis	2–3 days between treatments	A few hour between treatments
Conduction of dialysis	Needs visits to hospital (although home treatment is possible for some patients)	Performed at home
Requirement	Requires adequate venous circulation for vascular access	Requires an intact peritoneal cavity without major scarring from previous surgery
Diet and fluid restriction	Required between treatments	Diet and fluid less restricted
Speed of removal of fluid and associated symptoms	Fluid removal compressed into treatment periods. May cause symptoms and hemodynamic instability	Slow continuous fluid removal. Usually asymptomatic
Infections	Infections related to vascular access may occur	Peritonitis and catheter-related infections may occur
Dependency of patient	Patients are usually dependent on others	Patients can take fully responsibility for their treatment

Renal Transplantation

Q. Write a short essay/note on renal transplantation.

Successful renal transplantation offers the best chance of long-term survival with almost complete rehabilitation in ESRD.

Advantages

- Treatment of choice for most patients with advanced (end-stage) renal failure.
- Method of RRT having significant survival advantage when compared to dialysis patients.
- Freedom from dietary and fluid restriction
- Corrects anemia and infertility in CRF patients
- Reduces the need for parathyroidectomy

Donor is usually a living close relative or a cadaveric donor.

Factors Determining the Success

- **Donor:** Living donors should be healthy and should be **free of hypertension, diabetes, or malignant disease**. With the acceptance of the concept of brain death in India, cadaveric transplants are being also performed at present.
- **ABO (blood group) compatibility** between donor and recipient is required.
- **Matching donor and recipient for HLA type:**
- **Among the 6 HLA types in each person (A/B/C/DP/DQ/DR), three HLA types are matched (HLA-DR, HLA-B, HLA-A)**
    - It is preferable to have a donor with a HLA-identical that of the recipient. Matching for HLA-DR antigens (class II) appears to be most important for graft survival. Matching at the HLA-B locus (class I) has only a minor effect on graft outcomes.
    - Complete compatibility at HLA-A, HLA-B, and HLA-DR offers the best chance of long survival of the graft, followed by a single HLA mismatch (i.e., antigen possessed by the donor and not possessed by the recipient).
    - Class I antigens (HLA-A, B, and C) are detected by a lymphocyte assay and class II (HLA-DR) by mixed lymphocyte culture.
- **Cross-matching:** Presensitization (i.e., presence of antibodies against donor ABO blood group and HLA class I antigens) is detected by cross-matching. Transplantation is contraindicated if it is positive.

Contraindications (Table 10.36)

Technique

- Before transplantation, the recipient receives a hemodialysis to ensure a relatively normal metabolic state.
- In transplantation, donor human kidney (either from a cadaveric donor or from a living close relative) is placed in an extraperitoneal pouch in the **iliac fossa** of the recipient (**Fig. 10.30**).
- The renal artery and vein of donor kidney are anastomosed to the recipient's iliac vessels. The donor ureter is placed into the recipient's bladder. The recipient's original kidneys are left undisturbed.
- Eighty percent of grafts now survive for 5–10 years in the best centers, and 50% for 10–30 years.

TABLE 10.36: Absolute and relative contraindications for renal transplantation.

Absolute contraindications	***Relative contraindications***
Renal ➢ Reversible renal involvement ➢ Active glomerulonephritis ➢ Active vasculitis or recent anti-GBM disease **Non-renal** ➢ Disseminated or active untreated cancer ➢ Severe occlusive aortoiliac vascular disease ➢ Severe psychiatric disease ➢ Persistent substance abuse ➢ Severe mental retardation ➢ Active infection	➢ Age: Very young children (<1 year) or older people (>75 years) ➢ Iliofemoral occlusive disease ➢ Diabetes mellitus ➢ Severe diseases of lower urinary tract: Bladder dysfunction or urethral abnormalities ➢ Chronic liver disease ➢ Treated malignancy ➢ Significant comorbidity ➢ Previous sensitization to donor tissue ➢ Severe heart disease/refractory congestive heart failure

Immunosuppressive therapy

- Unless the donor is genetically identical (i.e., an identical twin), immunosuppressive treatment is required to prevent rejection.
- Immunosuppressive therapy varies from center to center and combination of drugs is often used.
- Commonly used drugs include corticosteroids, antiproliferative agents (e.g., azathioprine, mycophenolate mofetil), calcineurin inhibitor (e.g., ciclosporin, tacrolimus, sirolimus), and antibodies [polyclonal antithymocytic globulin (ATG), antilymphocytic globulin (ALG), and monoclonal (OKT3) antibodies]. Newer drugs include basiliximab and daclizumab (antibodies against interleukin-2 receptor).
- Immunosuppressive agents can be classified as:
  - Induction immunosuppression:
    - Depleting agents:
      - Anti-CD-52: Alemtuzumab
      - OKT3: Anti-CD3 monoclonal antibodies
      - Rabbit ATG
    - Nondepleting agents:
      - Anti-CD-25: Basiliximab, daclizumab
  - Maintenance immunosuppression:
    - Calcineurin inhibitors: Cyclosporine, tacrolimus
    - Mycophenolate mofetil
    - Steroids
    - mTOR inhibitors: Sirolimus

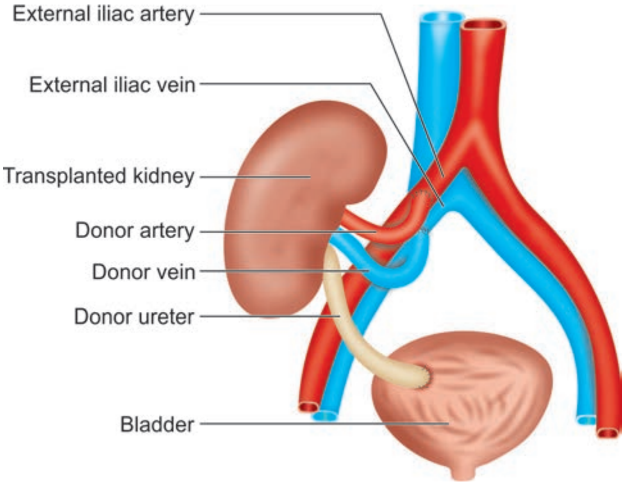

FIG. 10.30: Renal transplantation.

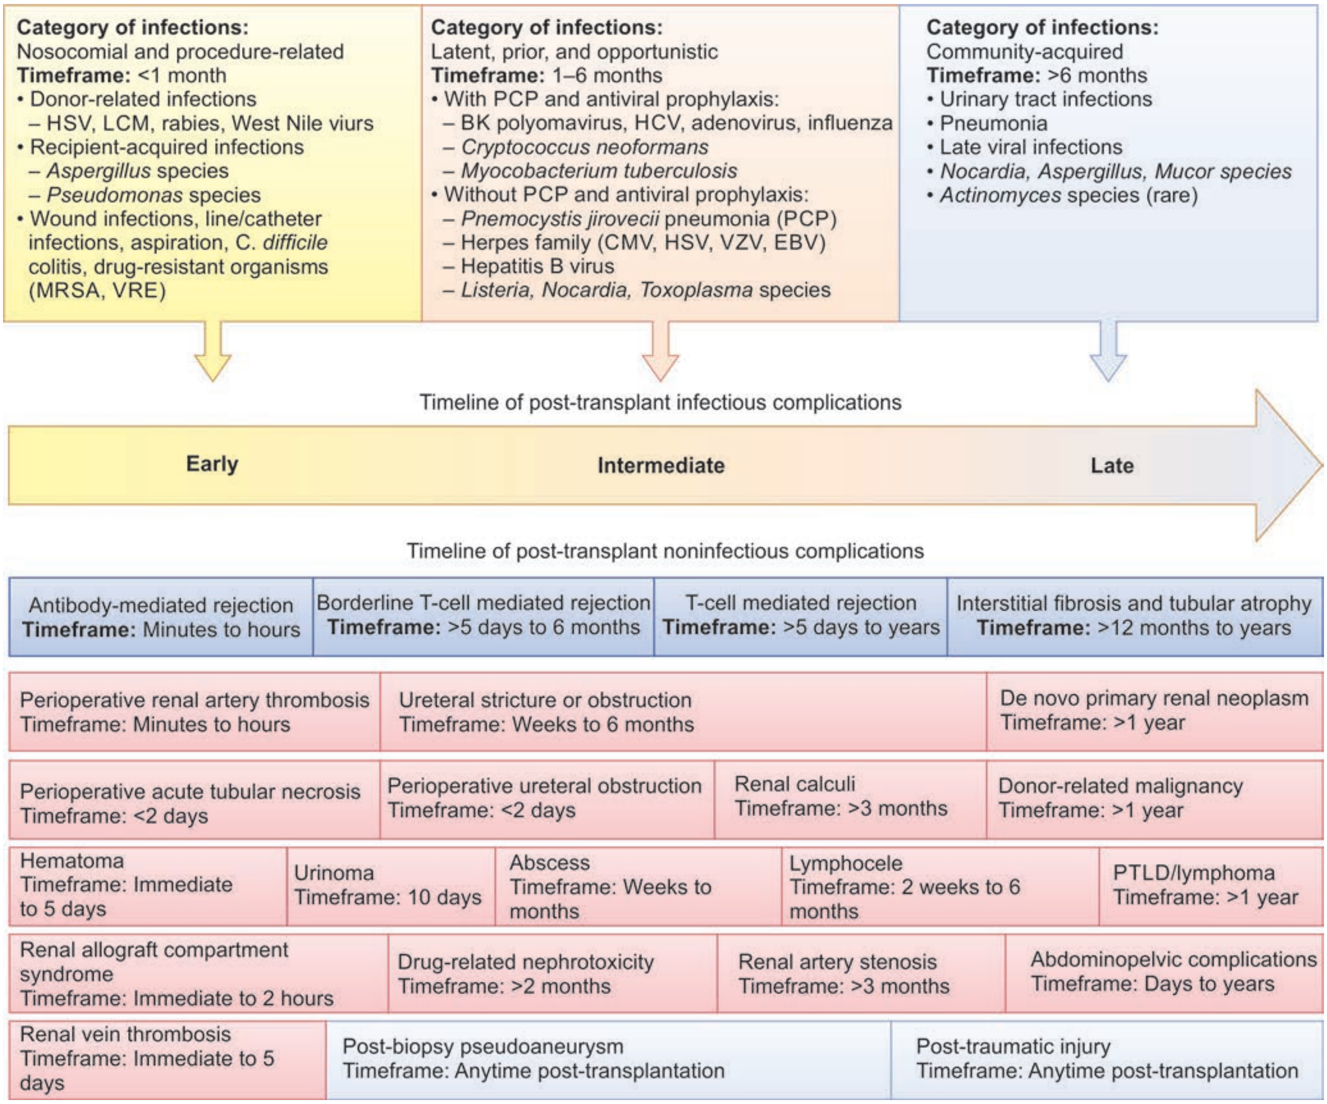
Complications (Fig. 10.31)

- **Acute tubular necrosis:** It is the most common cause of cadaveric graft dysfunction (up to 40–50%).
- **Technical failures:** These include (1) occlusion or stenosis of the arterial anastomosis, (2) occlusion of the venous anastomosis, and (3) urinary leaks owing to damage to the lower ureter, or defects in the anastomosis between ureter and recipient bladder.
- **Transplantation rejection:** In spite of prophylactic use of immune suppressants before or at the time of transplantation, after transplant also.
- Types of graft rejection:

Hyperacute rejection

- A special type of compliment-mediated rejection occurs if the host has **preformed anti-donor** antibodies (for example, anti-ABO blood type antibodies) in the circulation before transplantation. These antibodies bind to endothelium of graft organ, activates complement followed by vascular thrombosis.
- Occurs within minutes. The transplanted kidney must be removed immediately to prevent a severe systemic inflammatory response and generalized clotting.

  - **Acute rejection**
    - **Time of occurrence:** Within days to weeks after transplantation in the nonimmunosuppressed host.
    - **Type:** Either cellular or humoral immune mechanisms may predominate.
      - **Acute cellular rejection:** Occurs within few months after transplantation and develops renal failure.



Category of infections:
Nosocomial and procedure-related
Timeframe: <1 month
• Donor-related infections
– HSV, LCM, rabies, West Nile viurs
• Recipient-acquired infections
– Aspergillus species
– Pseudomonas species
• Wound infections, line/catheter infections, aspiration, C. difficile colitis, drug-resistant organisms (MRSA, VRE)
Category of infections:
Latent, prior, and opportunistic
Timeframe: 1–6 months
• With PCP and antiviral prophylaxis:
– BK polyomavirus, HCV, adenovirus, influenza
– Cryptococcus neoformans
– Myocobacterium tuberculosis
• Without PCP and antiviral prophylaxis:
– Pnemocystis jirovecii pneumonia (PCP)
– Herpes family (CMV, HSV, VZV, EBV)
– Hepatitis B virus
– Listeria, Nocardia, Toxoplasma species
Category of infections:
Community-acquired
Timeframe: >6 months
• Urinary tract infections
• Pneumonia
• Late viral infections
• Nocardia, Aspergillus, Mucor species
• Actinomyces species (rare)
Timeline of post-transplant infectious complications
Early
Intermediate
Late
Timeline of post-transplant noninfectious complications
Antibody-mediated rejection
Timeframe: Minutes to hours
Borderline T-cell mediated rejection
Timeframe: >5 days to 6 months
T-cell mediated rejection
Timeframe: >5 days to years
Interstitial fibrosis and tubular atrophy
Timeframe: >12 months to years
Perioperative renal artery thrombosis
Timeframe: Minutes to hours
Ureteral stricture or obstruction
Timeframe: Weeks to 6 months
De novo primary renal neoplasm
Timeframe: >1 year
Perioperative acute tubular necrosis
Timeframe: <2 days
Perioperative ureteral obstruction
Timeframe: <2 days
Renal calculi
Timeframe: >3 months
Donor-related malignancy
Timeframe: >1 year
Hematoma
Timeframe: Immediate to 5 days
Urinoma
Timeframe: 10 days
Abscess
Timeframe: Weeks to months
Lymphocele
Timeframe: 2 weeks to 6 months
PTLD/lymphoma
Timeframe: >1 year
Renal allograft compartment syndrome
Timeframe: Immediate to 2 hours
Drug-related nephrotoxicity
Timeframe: >2 months
Renal artery stenosis
Timeframe: >3 months
Abdominopelvic complications
Timeframe: Days to years
Renal vein thrombosis
Timeframe: Immediate to 5 days
Post-biopsy pseudoaneurysm
Timeframe: Anytime post-transplantation
Post-traumatic injury
Timeframe: Anytime post-transplantation

FIG. 10.31: Summary of post-transplant infectious and noninfectious complications.

- **Acute humoral rejection (rejection vasculitis):** Main target of the antibodies is the graft vasculature → manifest as vasculitis. Caused by anti-donor antibodies.
- **Features:** Acute rejection is characterized by deterioration of renal function, hypertension, weight gain, tenderness and swelling of the graft, fever and appearance of protein, lymphocytes, and renal tubular cells in the urine sediment.
- If the diagnosis is not clear, percutaneous needle biopsy is performed for histopathological examination.

Treatment

- Use additional immunosuppressant including intravenous pulses of methylprednisolone and antilymphocyte antibody.
- Antibody-mediated rejection is less likely to respond to corticosteroids and may be treated with plasma exchange (to remove the antibody) and intravenous immunoglobulin.

- **Chronic rejection:** Few patients may develop irreversible chronic graft rejection.

- **Other complications**
- **New-onset diabetes mellitus after transplantation (NODAT)**
  - **Infection** is the most important cause of morbidity and mortality. Risk of infections can be divided into three distinct time periods.

1. **First month post-transplant:** These include: (a) infections present in the recipient before transplant and aggravated by immunosuppressive therapy (e.g., tuberculosis, systemic fungal infections, hepatitis B or C, HIV or smoldering bacterial infections; (b) infections transmitted through contaminated allograft; and (c) routine postsurgical bacterial infections of the wound, IV lines, and urine catheters.

2. **1–6 months post-transplant:** These include: (a) viral infections (e.g., cytomegalovirus, Epstein–Barr virus, hepatitis viruses, and HIV) and (b) superinfection with opportunistic bacteria or fungi (e.g., *Pneumocystis carinii, Listeria monocytogenes,* and *Aspergillus*).
3. **More than 6 months post-transplant:** These include: (a) chronic progressive disease due to viral infections acquired earlier [e.g., progressive cytomegalovirus (CMV) chorioretinitis, progressive liver disease due to hepatitis B or C virus, and EBV-associated lymphoproliferative disorders]; (b) opportunistic infections with pathogens such as *Pneumocystis carinii, Cryptococcus*, *Listeria monocytogenes,* and *Nocardia asteroides* in patients with chronic graft dysfunction who have received multiple courses of antirejection therapy; and (c) infections similar to those in the community.

- **Post-transplantation lymphoproliferative disorders:** Epstein–Barr virus-associated malignancies are common in those who received biological agents and in children.
- **Malignancy:** Immunosuppressive therapy is associated with increases the risk of skin tumors (e.g., basal and squamous cell carcinoma). Incidence is 5–6% in western countries and lower (2%) in India.
- **Cardiovascular disease** is responsible for deaths in 20–30% of patients, especially the elderly and diabetics.
- **Post-transplant hypertension** develops in up to 80% of patients early in the postoperative course and in 50% of stable recipients on maintenance immunosuppression.
- **Post-transplant osteoporosis** is common due to treatment with steroids.
- **Recurrent and de novo renal disease** is common in few glomerular and renal stone disorders (e.g., primary FSGS, type II membranoproliferative glomerulonephritis, diabetic nephropathy and IgA nephropathy, hyperoxaluria).
- **Vascular:** Renal artery thrombosis and renal artery stenosis.
- **Urologic:** Ischemic necrosis of the lower end of the ureter may produce urinary leak, calyceal-cutaneous fistula. Vesicoureteric reflux into the graft may lead to increased frequency of UTIs.

TABLE 10.37: Indications for renal biopsy.

Condition	*Indications*
Nephrotic syndrome	Routinely indicated in adult NS In children: In SRNS
Nephritic syndrome	➢ Normal C3 at presentation ➢ After 6–8 weeks if: – Persistent low C3 – Gross hematuria – Nephrotic proteinuria ➢ RPGN-like presentation
Other glomerular diseases (Alport, IgA N, HUS, HSP)	to establish diagnosis
CKD	Normal kidney size
Renal transplant	To look for allograft dysfunction Done after ruling out: ➢ Urinary obstruction ➢ Urinary sepsis ➢ RAS ➢ Toxic CNI levels
AKI	To look for unknown etiology of AKI once prerenal and postrenal causes and acute tubular necrosis ruled out
Systemic disease with renal dysfunction	➢ Small vessel vasculitis ➢ Anti-GBM ➢ Lupus ➢ Diabetes: Only if atypical features present
Rapidly progressive renal failure	

(AKI: Acute kidney injury; CKD: Chronic kidney disease; CNI: Calcineurin inhibitor; GBM: Glomerular basement membrane; HSP: Henoch-Schönlein purpura; HUS: Hemolytic uremic syndrome; IgA: Immunoglobulin A; IgA N: IgA nephropathy; RAS: Renin-angiotensin system; RPGN: Rapidly progressive glomerulonephritis; SRNS: Steroid-resistant nephrotic syndrome)

RENAL BIOPSY

Q. Write short note on renal biopsy and its indications.

It is used to establish the nature and extent of renal disease. Biopsy is performed transcutaneously with ultrasound guidance. Biopsy material is examined under light microscopy, electron microscopy and by immunofluorescence. Indications for renal biopsy are presented in **Table 10.37** and contraindications and complications of renal biopsy are presented in **Table 10.38**.

TABLE 10.38: Contraindications and complications of renal biopsy.

Contraindications	*Complications*
➢ Coagulation disorders ➢ Thrombocytopenia ➢ Uncontrolled hypertension ➢ Solitary kidney ➢ Renal neoplasms (to avoid spread along needle track) ➢ Large and multiple renal cysts ➢ Acute urinary tract infections ➢ Urinary tract obstructions ➢ Kidney less than 60% predicted size	➢ Pain ➢ Infection ➢ Bleeding into the urine ➢ Bleeding around kidney ➢ Arteriovenous fistula ➢ Accidental biopsy of other organ or perforation of organs such as liver, spleen ➢ Rarely death

CHAPTER 11

Fluid and Electrolyte Disturbances

DISORDERS OF WATER BALANCE

Q. Write short note on the normal distribution of water in the body of an average adult male.

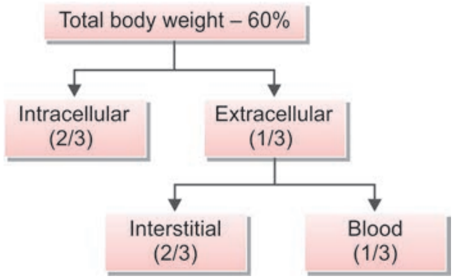
Composition of Body Fluids

- Water is the most abundant constituent of the body, accounting for about 50% of body weight in women and 60% of the body weight in men.
- Total body water is distributed in two major compartments:
  1. Intracellular fluid compartment (IFC) = 2/3rd of body water
  2. Extracellular fluid compartment (ECF) = 1/3rd of body water

     ECF consists of:
     - **Intravascular (plasma water)** compartment: 3/4th of ECF or 15% of total body weight.
     - **Extravascular (interstitial)** compartment: 1/4th of ECF or 5% of total body weight.

  For example, the distribution of body fluid in a man of 70 kg is as mentioned in **Flowchart 11.1.**

FLOWCHART 11.1: Distribution of body fluid compartments.



Normal Water Balance

- In a normal person, daily fluid requirement = sum of urine output + net insensible fluid losses
  - Insensible fluid loss = 500 mL through skin + 400 mL through lung + 100 mL through stool = 1,000 mL
  - Insensible fluid input = 300 mL water through oxidation
  - Net normal daily insensible fluid loss = 1,000 mL – 300 mL = 700 mL
- *Hence, daily fluid requirement = urine output + 700 mL*
- Abnormal fluid loss:
  - 500 mL through moderate sweating
  - 1–1.5 L through severe sweating/high fever
  - 0.5–3 L through exposed wound surface (burns) and body cavity (laparotomy)
  - These parameters help to determine the daily fluid requirement in patients, especially those on intravenous fluids.

Electrolytes (Table 11.1)

- Electrolytes are ions that are either positively charged (cations) or negatively charged (anions).
- Sodium (Na^+) is the main cation, while chloride (Cl^-) and bicarbonate (HCO^-) are the major anions in the extracellular (ECF) compartment.
- Potassium (K^+) and magnesium (Mg^{2+}) are the major cations, while phosphate, sulfate, and protein are the major anions in the intracellular (ICF) compartment.
- The normal range of different electrolytes in the blood is as shown in **Table 11.1.**

TABLE 11.1: Normal range of various electrolytes, pH, and osmolality of blood.

Component	*Normal range*	*Component*	*Normal range*
Sodium (serum)	136–145 mmol/L	Calcium (plasma)	9–10.5 mg/dL
Potassium (serum)	3.5–5.0 mmol/L	pH of blood	7.35–7.45
Chloride (serum)	98–106 mmol/L	Bicarbonate (blood)	21–28 mmol/L
Magnesium (serum)	2–3 mg/L	Osmolality (serum)	285–290 mOsm/kg water
Phosphorus (serum)	3–4.5 mg/dL		

OSMOLALITY, OSMOLARITY, AND TONICITY

- **Osmolality:** Osmolality of a solution is determined by the amount of solute dissolved in a solvent (i.e., water) measured in weight (kg). When osmolality is high, solution is more concentrated, and when the osmolality is low, solution is diluted.
- **Osmolarity:** Osmolarity is the concentration of osmotically active particles, expressed as milliosmoles per liter (mOsm/L).
- Plasma osmolarity = 2 × Na^+ (mEq/L) + glucose (mg/dL)/18 + BUN (mg/dL)/2.8
- In practice, *osmola'r'ity* is the same as *osmola'l'ity* (mOsm/kg H_2O) because 1 L of water is equivalent to 1 kg of water.
- **Tonicity vs osmolality:**
  - Osmolality refers to all particles in solution
  - Tonicity describes whether the particles are effective or ineffective osmoles.
  - Tonicity = concentration of solutes that do not cross the cell membrane = effective serum osmolality.
  - A small note on effective vs ineffective osmoles—urea, ethanol, methanol, ethylene glycol are ineffective osmoles. Glucose, mannitol, glycine and maltose are effective osmoles.

VOLUME REGULATION AND OSMOREGULATION

Q. What are the factors that determine the control of ECF volume?

Q. Write a note on sodium balance.

Total body sodium is the main determinant of ECF volume: Regulation of the sodium balance, i.e., the difference between sodium intake and output, is crucial to maintaining normal ECF and plasma volume, with the kidney matching the urinary output of sodium with that of sodium intake.

A positive Na^+ balance would lead to ECF volume expansion, while conversely, a negative Na^+ balance would lead to ECF volume contraction.

Sodium intake: Daily sodium consumption varies widely between low-Na^+ diets containing 20 mmol/day (approximately 1.2 g salt/day) and high-Na^+ diets containing 200 mmol/day (approximately 12 g salt/day).

Sodium excretion: Figure 11.1 shows the renal handling of sodium by the nephron.

Na^+ is freely filtered across glomerular capillaries and is subsequently reabsorbed throughout the nephron.

- *Proximal convoluted tubule (PCT)*: Approximately 2/3rd (67%) of Na^+ is reabsorbed.
- *The loop of Henle*: About 25–30% is reabsorbed via apical $Na^+ K^+ 2Cl^-$ transporter.
- *Distal convoluted tubule (DCT)*: About 5% by thiazide sensitive $Na^+ Cl^-$ cotransporter.
- *Collecting ducts*: About 3% of Na^+ reabsorption takes place in the cortical and medullary collecting ducts.

The excretion of Na^+ is less than 1% of the filtered load, with more than 99% of the filtered load being reabsorbed.

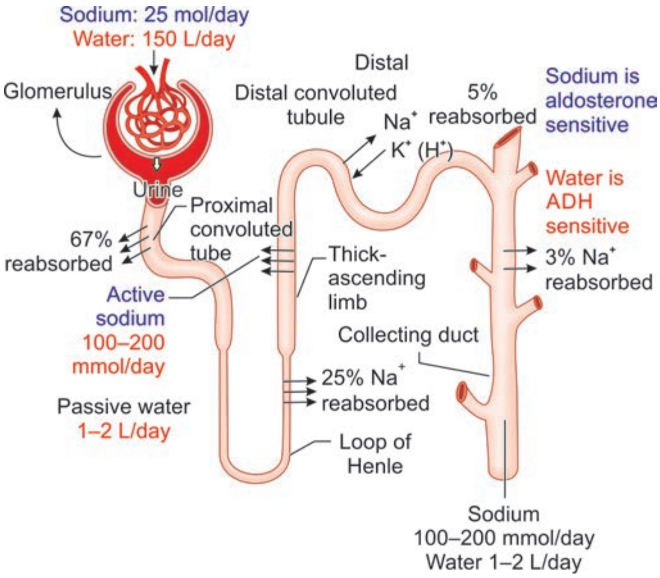


FIG. 11.1: Regulation of sodium excretion by kidney.

Renal excretion of sodium is regulated by four major steps:

1. *Renin–angiotensin–aldosterone system*:
   - The renin–angiotensin–aldosterone system is activated in response to decreased renal perfusion pressure.
   - Angiotensin II stimulates Na^+ reabsorption in the proximal tubule (Na^+–H^+ exchange).
   - Aldosterone stimulates Na^+ reabsorption in the late distal tubule and the collecting duct.
2. *Sympathetic nervous system (SNS) activity*: Baroreceptors sense a decrease in arterial pressure and stimulate the SNS and cause vasoconstriction of afferent arterioles and increased proximal tubular sodium reabsorption.
3. *Atrial natriuretic peptide (ANP)*:
   - ANP—secreted by the atria in response to an increase in ECF volume, causes vasodilation of afferent arterioles, vasoconstriction of efferent arterioles, increased GFR, and decreased Na^+ reabsorption in the late distal tubule and collecting ducts.

- Other peptides in the ANP family, including urodilatin (secreted by the kidney) and brain natriuretic peptide (BNP) (secreted by cardiac ventricular cells and the brain), have similar effects to increase GFR and decrease renal sodium reabsorption.

4. *Starling forces in peritubular capillaries*:
    - Increase in ECF volume reduces the peritubular capillary oncotic pressure and inhibit proximal tubule Na^+ reabsorption.
    - Decrease in ECF volume increases the peritubular capillary oncotic pressure and stimulate proximal tubule Na^+ reabsorption.

Body fluid osmolarity is maintained at a value of about 285–290 mOsm/L by processes called osmoregulation.

Even minor changes in body fluid osmolarity produce a series of hormonal responses that influence the reabsorption of water by the kidneys, attempting to restore osmolarity back to normal value.

These renal mechanisms for the reabsorption of water are responsible for maintaining constant body fluid osmolarity.

Vasopressin, also known as **arginine vasopressin (AVP)** or **antidiuretic hormone (ADH)**, by its effect on the renal collecting system, is the major determinant which regulates the excretion of free water.

Increased serum osmolality stimulates osmoreceptors in the anterior hypothalamus, which in turn stimulates thirst and the secretion of ADH from the posterior pituitary gland. ADH circulates via the blood to the kidneys, where it leads to the increase in the water permeability of the principal cells of the late distal tubule and the collecting duct, resulting in increased water reabsorption. Because more water is reabsorbed by these segments, the osmolarity of urine increases and the amount of urine decreases. This, along with increased water intake, restores serum osmolarity to normal levels.

Conversely, reduced serum osmolarity, via inhibition of the osmoreceptors in the anterior hypothalamus, suppresses thirst as well as the secretion of ADH, which results in excretion of large amount dilute urine, restoring serum osmolarity to normal levels.

Table 11.2 summarizes the factors which determine volume and osmoregulation.

TABLE 11.2: Determinants of volume regulation and osmoregulation.

Factor	*Volume regulation*	*Osmoregulation*
Factor sensed	Effective arterial blood volume	Plasma osmolality
Sensed by	Baroreceptors	Hypothalamic osmoreceptors
Effectors	Aldosterone, angiotensin II, sympathetic nervous system	Antidiuretic hormone, thirst
What is affected	Urine sodium excretion	Urine osmolality, thirst

ASSESSING VOLUME STATUS

Q. How do you asses volume status?

Hemodynamic assessment methods include:

- Interpretation of history and physical examination findings
- Assessment and interpretation of laboratory results
- Ultrasound and echocardiography
- Use of noninvasive monitoring
- Use of minimally invasive procedures

No single assessment is sufficient in isolation and must be considered in the context of other available assessments and clinical information.

Some of the methods used in clinical practice are described in **Table 11.3**.

TABLE 11.3: Assessment of volume status.

Method	*Features*	*Invasive/ Noninvasive*	*Static or dynamic*	*Assesses fluid responsiveness*	*Comment*
History	Thirst/vomiting/diarrhea/hemorrhage: Indicate fluid deficit Dyspnea and pedal edema favor fluid overload	Noninvasive	Static	No	–
Charting	Fluid balance charts (input/output charting) 24-hour weighing—best measure of change in water balance	Noninvasivea	Dynamic	Yes	Fluid balance charts do not measure insensible loss and may have irregularities in measurement and recording Weighing may be difficult in critically ill patient

Contd...

Contd...

Method	***Features***	***Invasive/ Noninvasive***	***Static or dynamic***	***Assesses fluid responsiveness***	***Comment***
Physical examination	Tachycardia, postural hypotension, low JVP, cold extremities, poor capillary return, dry mouth, sunken facies, altered mentation, and reduced urine output suggest hypovolemia Pulmonary edema, peripheral edema, raised JVP, and S3 gallop suggests volume overload	Noninvasive	Static and dynamic	Yes	Serial examinations may detect changes in organ perfusion
Passive leg raising (PLR)	The head and the upper torso are lowered to a supine position, while simultaneously raising the legs to a 45° angle for 4 minutes. This increases the venous return to the heart and is similar to the administration of 250 mL of fluid bolus. Hemodynamics are assessed before and after the PLR; if cardiac output improves, the patient is "fluid responsive" and administration of IV fluids should improve hemodynamics	Noninvasive	Dynamic	Yes	Unreliable with intra-abdominal hypertension, DVT in the leg, lower limb amputation
Biochemistry	Higher BUN: Creatinine ratio (>20:1), reduced urine sodium levels (<25 mEq/L), increased lactates suggest hypovolemia	Invasive	Static	No	Affected by drugs and other clinical conditions
Bedside ultrasound and echocardiography	Heart: Measurement of cardiac chamber function, pericardial tamponade Inferior vena cava: Collapse >50% indicates fluid tolerance Lung ultrasonography: More B lines correspond with increasing fluid overload. Also helps to identify pneumothorax, which causes obstructive shock	Noninvasive	Static and dynamic	Yes	Helps to identify various causes of shock such as cardiogenic, hypovolemic or obstructive
Central venous pressure	Central venous catheters through IJV or subclavian vein can be used to measure CVP Normal: 4–8 mm Hg Low CVP—hypovolemia High CVP—volume overload, cardiac causes such as CHF, cardiac tamponade, tricuspid regurgitation, pulmonary causes such as pulmonary embolism, tension pneumothorax, intermittent positive pressure ventilation	Invasive	Statica	No	Poor correlation with fluid responsiveness
Pulmonary capillary wedge pressure (Swan-Ganz catheter)	A Swan-Ganz catheter is inserted through the IJV or the subclavian vein, and into the right atrium and ventricle to end in the pulmonary artery Commonly used in the management of postoperative cardiac patients and those with severe pulmonary hypertension	Invasive	Static	No	Poor correlation with fluid responsiveness
Stroke volume or pulse pressure variation	Pulse pressure analysis using data obtained form an arterial line helps to determine fluid responsiveness Steep variation—fluid responsiveness	Invasive	Dynamic	Yes	Requires sedated, mechanically ventilated patient
Transesophageal Doppler	A transducer is inserted into the esophagus to obtain accurate measures of stroke volume and cardiac output	Invasive	Dynamic	Yes	Not useful for continuous measurements
Thoracic electrical bioimpedance	Bioimpedance measures the resistance of electrical current through different body tissue and fluids, and can quantify the amount of tissue and fluid in the body	Noninvasive	Static	No	Not able to assess intravascular volume

DISTURBANCES OF BODY FLUIDS

The disturbances of body fluids can be grouped according to whether they involve volume contraction or volume expansion and whether they involve an increase or a decrease in body fluid osmolarity are described in **Table 11.4** and **Figure 11.2.**

TABLE 11.4: Disturbances in body fluids.

Type	*Example*	*ECF volume*	*ICF volume*	*Osmolarity*	*Hematocrit*	*Plasma (Protein)*
Isosmotic volume contraction	Diarrhea; burn	↓	No change	No change	↑	↑
Hyperosmotic volume contraction	Sweating, fever, diabetes insipidus	↓	↓	↑	No change	↑
Hyposmotic volume contraction	Adrenal insufficiency	↓	↑	↓	↑	↑
Isosmotic volume expansion	Infusion of isotonic NaCl	↑	No change	No change	↓	↓
Hyperosmotic volume expansion	High-NaCl intake	↑	↓	↑	↓	↓
Hyposmotic volume expansion	Syndrome of inappropriate antidiuretic hormone secretion (SIADH)	↑	↑	↓	No change	↓

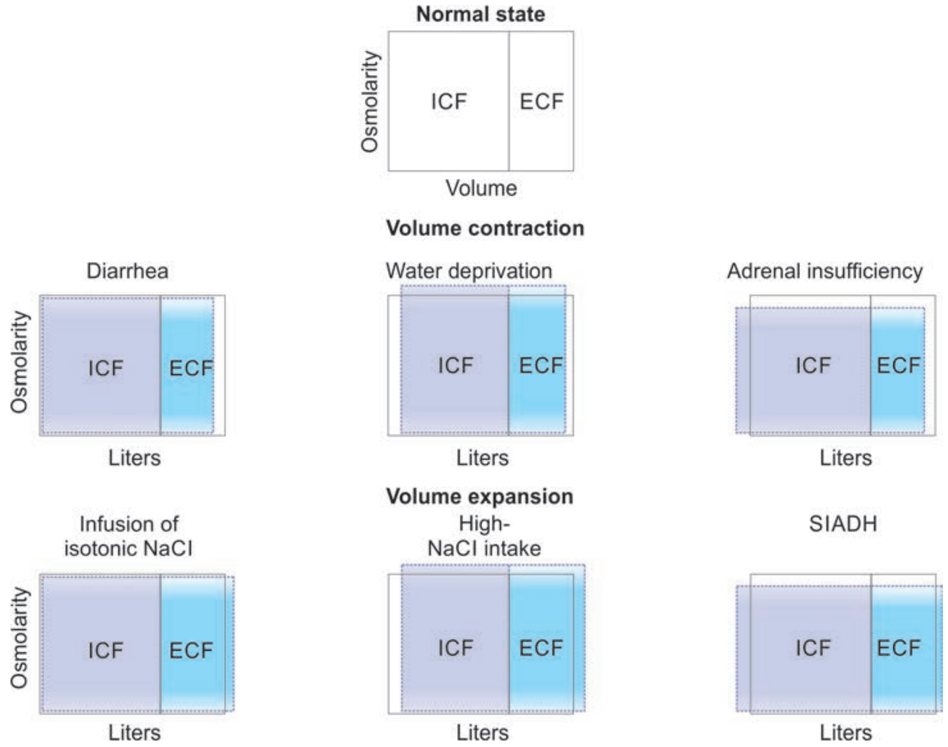

FIG. 11.2: Shifts of water between body fluid compartments.

VOLUME DEPLETION (HYPOVOLEMIA)

Q. What is hypovolemia?

Hypovolemia, synonymous with ECF volume contraction, refers to a loss of salt and water.

Q. Describe the causes, clinical features, laboratory features, and treatment of volume depletion.

Causes of Hypovolemia

See **Table 11.5**.

TABLE 11.5: Causes of volume depletion (hypovolemia).

Extrarenal losses	*Renal losses*
➢ *Gastrointestinal losses*: – Diarrhea – Vomiting – Gastrointestinal bleeding – External drain (tube drainage or ostomies) ➢ *Sequestration into third space*: – Pancreatitis – Crush injuries – Intestinal obstruction – Skeletal fractures ➢ *Loss from skin*: – Excessive sweating – Burns	➢ *Excessive use of diuretics*: – Osmotic diuresis – Glycosuria in uncontrolled diabetes – Excessive use of mannitol ➢ *Diabetes insipidus*: Impaired ADH secretion/response to ADH ➢ *Renal disease:* – Tubular disorders – Recovery phase of oliguric kidney injury – Release of urinary tract obstruction – Chronic interstitial renal diseases ➢ *Deficiency of mineralocorticoids*: – Addison's disease

Clinical Features

Mild to Moderate Volume Loss

- Thirst
- Postural dizziness, weakness
- Dry mucous membranes and axillae
- Cold, clammy extremities
- Collapsed peripheral veins
- Delayed capillary refill time
- Tachycardia (pulse rate >100 beats/min)
- Postural increase in pulse of 30 beats/min or more

- Postural hypotension (systolic blood pressure decrease >20 mm Hg on standing)
- Low jugular venous pulse
- Decreased urine output

Severe Volume Loss and Hypovolemic Shock

- Altered mental status (or loss of consciousness)
- Peripheral cyanosis
- Reduced skin turgor (in young patients)
- Marked tachycardia, low pulse volume
- Supine hypotension (systolic blood pressure <100 mm Hg)

Laboratory Features

- **Hematocrit:** Increased due to hemoconcentration. May be reduced if hypovolemia is secondary to hemorrhage.
- **Blood urea nitrogen (BUN) and creatinine:** BUN/creatinine ratio >20:1 is usually seen. This is due to a differential increase in urea reabsorption in the collecting duct. Confounding factors include upper gastrointestinal tract hemorrhage and administration of corticosteroids, which increase urea production, as well as malnutrition and liver disease, which diminish urea production.
- **Serum sodium:** Normal, reduced, or elevated depending on the proportion of loss between water and sodium.
- **Urine osmolality and specific gravity:** These are often elevated in hypovolemic states. However, these may be altered by an underlying renal disease that leads to renal sodium wasting, concomitant intake of diuretics or a solute diuresis.
- **Urinary sodium:** Hypovolemia normally promotes renal sodium reabsorption. Hence, urine sodium is low, typically less than 25 mmol/L in most cases of hypovolemia and states of low effective arterial volume. However, urine sodium concentration may be misleading in cases of:
  - Metabolic alkalosis (e.g. nasogastric suction or vomiting), as bicarbonaturia obligates excretion of a cation. Hence, the urine sodium concentration might not be low. In this circumstance, the urine chloride concentration should be measured, which will typically be <15 mEq/L.
  - Presence of acute tubular necrosis—kidney tubular function is impaired, thus the urine sodium concentration may not be low.
  - Use of diuretics
- **Urine chloride levels (low):** It follows a similar pattern of urine sodium concentration because sodium and chloride are generally reabsorbed together. Urine chloride is a better measure than urine sodium in cases of volume depletion with metabolic alkalosis, as described above.
- **Fractional excretion of sodium (FE Na)**:
  - $[U_{Na} \times P_{creat}/U_{creat} \times P_{Na}] \times 100$.
  - In an oliguric patient with AKI, FE Na less than 1% is consistent with volume depletion; FE Na greater than 1% is more consistent with acute tubular necrosis.

Treatment:

- The goal of treatment is to replace the fluid deficit and ongoing losses with a fluid that resembles the lost fluid.
- The cause of hypovolemia should be treated, where possible.
- Mild-to-moderate volume depletion (often due to gastroenteritis) should be corrected by increasing oral intake of sodium and water by an oral rehydration solution.
- In severe volume depletion, intravenous crystalloids such as normal saline or Ringer's lactate are usually the preferred initial choice for volume resuscitation.
- Transfusion of blood products is crucial for hemorrhage.

Q. What is dehydration? Describe the clinical features of dehydration.

- Dehydration refers to a loss of water.
- This should be differentiated from hypovolemia, which implies a loss of salt and water.
- Dehydration may cause manifestations of hypernatremia.
- **Table 11.6** describes the signs of dehydration depending on the degree of dehydration.

TABLE 11.6: Signs of dehydration depending on the degree of dehydration.

	Degree of dehydration		
Features	***Mild***	***Moderate***	***Severe***
Peripheral pulses	Normal	Slightly decreased	Difficult to palpate
Heart rate	Normal	Slightly increased	Significant increased with tachycardia
Capillary refill	Normal	About 2 seconds	>3 seconds
Mucus membranes and skin	Normal	Dry	Extremely dry
Eyes	Normal	Normal	Shrunken
Production of tears	Normal	Decreased	Absent
Amount of urine excreted	Normal	Decreased	Little or none
Fontanelle (in infants)	Flat	Soft	Shrunken

VOLUME EXPANSION (HYPERVOLEMIA)

- Hypervolemia is an expansion of the ECF compartment, due to an excess of total body sodium and water.
- Hypervolemia is typically due to renal retention of sodium and water.
- This renal retention may be primary or secondary.
- Secondary causes are secondary to reduced effective arterial blood volume depletion (arterial underfilling).
- Major causes of hypervolemia are listed in **Table 11.7**.

TABLE 11.7: Major causes of extracellular fluid volume expansion.

Primary renal sodium retention	*Secondary renal sodium retention*
➢ Acute kidney injury ➢ Advanced chronic kidney disease ➢ Glomerular diseases	➢ Cardiac failure ➢ Cirrhosis ➢ Nephrotic syndrome ➢ Idiopathic edema ➢ Drug-induced edema ➢ Pregnancy

EDEMA

Q. Define edema. What is anasarca?

Q. What are the common causes of generalized edema?

Q. List medications that can cause edema.

Q. Discuss the mechanism of edema formation. How will you differentiate between cardiac, renal and hepatic edema?

Definition

Edema: Edema is an accumulation of fluid in the interstitial space that occurs when local or systemic conditions cause capillary filtration to exceed the limits of lymphatic drainage.

Anasarca: It refers to generalized and massive edema, often accompanied by large effusions into the peritoneal, pleural, and pericardial spaces.

Table 11.8 shows the medications that cause edema.

Differences between the principal causes of edema are described in **Table 11.9**.

TABLE 11.8: Medications that cause edema.

Types of medication	*Class of medication*
Antihypertensive medications	➢ Calcium-channel blockers (nifedipine, felodipine, amlodipine, and verapamil) ➢ Direct vasodilators (hydralazine, minoxidil, diazoxide) ➢ Antiadrenergics (clonidine, reserpine, and methyldopa)
Chemotherapy	Cisplatin and docetaxel
Diabetic medications	Thiazolidinediones (rosiglitazone), insulin
Hormones	Estrogen, progesterone, testosterone, glucocorticoids, and fludrocortisone
Pain relief medications	NSAIDs
Psychiatric medications	➢ Monoamine oxidase inhibitors ➢ Antipsychotics (olanzapine)
Immunological/ Immunosuppressant	Cyclophosphamide, cyclosporine, interleukin 2, OKT3 monoclonal antibody
Anticonvulsant	Pregabalin and gabapentin

Causes of Pitting Dependent Edema (Table 11.10)

Pathogenesis of systemic edema from congestive heart failure, renal failure, or reduced plasma osmotic pressure is shown in **Figure 11.3**.

Pitting edema may be divided into two categories:

1. **Rapid pitting** recovery within <40 seconds and is seen with hypoproteinemia.
2. **Slow pitting edema** (>40 seconds) is usually seen in patients with normal albumin levels **(Fig. 11.4)**.

TABLE 11.9: Differentiating the principal causes of generalized edema.

Organ system	*History*	*Physical examination*	*Laboratory findings*
Cardiac	➢ Exertional dyspnea ➢ Paroxysmal nocturnal dyspnea ➢ Orthopnea ➢ Bendopnea ➢ Initial site of edema: pedal edema/ sacral edema	Pulsus alternans, elevated jugular venous pressure, displaced or dyskinetic apical pulse, S3 gallop	Elevated BNP/NT-proBNP
Hepatic	➢ Ascites ➢ Dyspnea, when associated with significant degree of ascites ➢ Jaundice	➢ Ascites ➢ Signs of chronic liver disease (jaundice, palmar erythema, spider angiomata, male gynecomastia or female breast atrophy, testicular atrophy; signs of hepatic encephalopathy) may be present ➢ Jugular venous pressure normal or low	➢ Reduced serum albumin, other hepatic proteins (transferrin, fibrinogen) ➢ Elevated PT/INR ➢ Liver enzymes may be elevated, depending on the cause and acuity of liver injury ➢ Thrombocytopenia may be present

Contd...

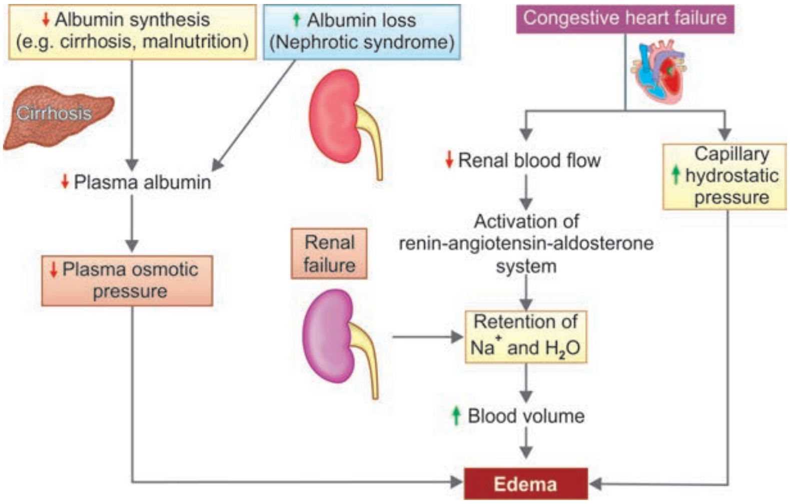
Organ system	***History***	***Physical examination***	***Laboratory findings***
Renal (CKD)	➢ Symptoms of uremia, such as decreased appetite, nausea and vomiting, altered (metallic or fishy) taste, altered sleep pattern, difficulty concentrating ➢ Decreased urine output ➢ Dyspnea	➢ Pallor ➢ Hypertension ➢ Uremic fetor ➢ Pericardial friction rub	➢ Elevation of serum creatinine and cystatin C ➢ Proteinuria ➢ Hematuria ➢ Hyperkalemia ➢ Metabolic acidosis ➢ Hypocalcemia ➢ Hyperphosphatemia ➢ Anemia
Renal (nephrotic syndrome)	➢ Periorbital edema ➢ Frothy urine	➢ Periorbital edema ➢ Hypertension	➢ Proteinuria (≥3.5 g/dL) ➢ Hypoalbuminemia ➢ Hypercholesterolemia ➢ Microscopic hematuria

TABLE 11.10: Causes of pitting dependent edema.

Mechanism	***Causes***
Increased hydrostatic/ systemic venous pressure	**Systemic venous hypertension:** ➢ Congestive heart failure ➢ Pericardial diseases, constrictive pericarditis and tricuspid valve disease **Regional venous hypertension:** ➢ Inferior vena cava syndrome ➢ Obstruction (e.g., venous thrombosis*) or compression of veins (e.g., external mass) ➢ Lower extremity venous insufficiency
Decreased plasma oncotic pressure (hypoproteinemia)	**Impaired protein synthesis:** ➢ *Decreased protein intake*: Starvation, kwashiorkor, and malnutrition ➢ *Decreased absorption of proteins*: Malabsorption ➢ Impaired hepatic synthesis due to liver disease **Increased loss of protein:** ➢ *Skin loss*: Burns, weeping skin diseases ➢ *Urinary loss*: Nephrotic syndrome ➢ *Fecal loss*: Bowel disease, malabsorption, protein-losing gastroenteropathy
Inflammation	Acute* and chronic inflammation*
Increased capillary permeability	Vasculitis*, idiopathic cyclic edema of women (varies with menstrual cycle), and postanoxic encephalopathy
Sodium retention	➢ Excessive salt intake with renal insufficiency ➢ Increased tubular reabsorption of sodium, e.g., increased renin-angiotensin-aldosterone secretion

*Causes painful edema



↓Albumin synthesis (e.g. cirrhosis, malnutrition)
↑Albumin loss (Nephrotic syndrome)
Congestive heart failure
Cirrhosis
↓Plasma albumin
↓Renal blood flow
Capillary ↑hydrostatic pressure
Activation of renin-angiotensin-aldosterone system
Renal failure
↓Plasma osmotic pressure
Retention of Na⁺ and H₂O
↑Blood volume
Edema

FIG. 11.3: Pathogenesis of systemic edema from congestive heart failure, renal failure or reduced plasma osmotic pressure.

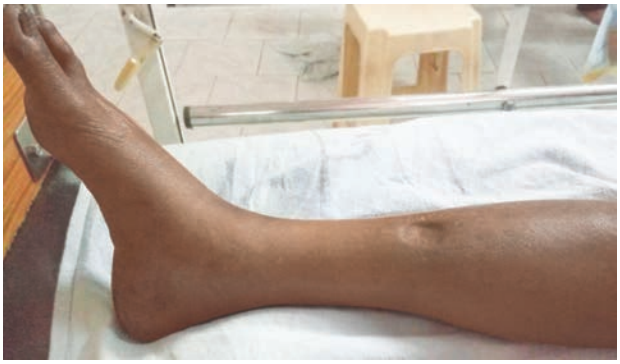


FIG. 11.4: Pitting edema in congestive heart failure.

Treatment of Extracellular Volume Expansion

Q. Discuss the principles of management of extracellular volume expansion/generalized edema.

General Management

- Recognize and treat the underlying cause
- Medications that promote sodium retention (e.g., NSAIDs) should be discontinued.
- Achieving negative sodium balance, by dietary sodium restriction and administration of diuretics.
  - Moderate dietary sodium restriction (2 g Na^+/day) should be encouraged.
  - Restriction of total fluid intake in patients with hypervolemic hyponatremia.
  - *Diuretic therapy:* Cornerstone of management of extracellular volume overload (described later).

Additional specific therapy based on the etiology:

- *Liver cirrhosis:* Large volume paracentesis with albumin infusion, TIPS (transjugular intrahepatic portosystemic shunt).
- *Heart failure:* Use of ACE inhibitors and angiotensin receptor blockers (ARBs) to inhibit renin-angiotensin-aldosterone system (RAAS), ultrafiltration, and left ventricular assist devices.
- *Chronic kidney disease:* ACE inhibitors and ARBs, renal replacement therapy (dialysis and kidney transplant).
- *Nephrotic syndrome:* Use of glucocorticoids, ACE inhibitors, and ARBs.
- *Edema of nutritional origin:* Thiamine for beriberi, high protein diet.

DIURETIC THERAPY

Q. Describe various diuretics in use.

Q. Add a note on diuretic therapy in edematous patients.

- Diuretics are the cornerstone in the management of extracellular volume overload. They are also used in the management of hypertension.
- They act by inhibiting sodium reabsorption at various locations along the nephron.
- **Table 11.11** provides a summary of the various subclasses of diuretics.
- Caution should be exercised during therapy with diuretics as ECF volume expansion may have occurred in order to compensate for arterial underfilling, as in cirrhosis and heart failure.
- In these cases, overly rapid diuresis may lead to a significant reduction in the vascular space, which leads to decreased venous return to the heart, decreased cardiac filling pressures, decreased stroke volume, decreased cardiac output, and ultimately hypotension. Impaired renal perfusion may lead to prerenal AKI.
- This situation is more commonly seen in those patients with ascites, but without pedal edema.
- Rapid removal of excess fluid is generally necessary only in life-threatening situations, such as pulmonary edema and hypervolemia-induced hypertension.
- Most patients generally tolerate gradual correction of volume overload.

TABLE 11.11: Summary of diuretics.

Subclass, drug	*Site of action*	*Mechanism of action*	*Clinical uses*	*Toxicities*	*Comments*
Loop diuretics					
Furosemide, bumetanide, torsemide (sulfonamide loop diuretics) Ethacrynic acid: Not a sulfonamide but has typical loop activity and some uricosuric action	Ascending limb of Henle's loop	Inhibition of the Na/K/2Cl channel, leading to marked increase in NaCl excretion, K^+ wasting, metabolic alkalosis, increased urine Ca^{2+} and Mg^{2+}	Pulmonary edema, peripheral edema, heart failure, hypertension, acute hypercalcemia, type IV RTA	Ototoxicity, hypovolemia, K wasting, hyperuricemia, hypomagnesemia	Potent diuretics used in diseases associated with significant edema
Thiazides					
Hydrochlorothiazide, metolazone Chlorothiazide: *Only parenteral thiazide available (IV)* Chlorthalidone	Distal convoluted tubule (DCT)	Inhibition of Na/Cl transporter in the distal convoluted tubule leads to increase in NaCl excretion, some K wasting, metabolic alkalosis, decreased urine Ca^{2+}	Hypertension, mild heart failure, nephrolithiasis, nephrogenic diabetes insipidus, osteoporosis	Hyponatremia, hypokalemia, metabolic alkalosis, hyperuricemia, hyperglycemia	Widely used in the treatment of hypertension and less severe edema. Metolazone is commonly used along with loop diuretic for "sequential blockade"
Potassium-sparing diuretics					
Spironolactone Eplerenone	Collecting tubules-alpha-intercalated cells	Aldosterone antagonists: Reduce Na retention and K wasting in kidney	Cirrhosis of liver (up to 400 mg/day of spironolactone), heart failure with reduced ejection fraction (25–50 mg/day of spironolactone), hypertension associated with hyperaldosteronism and resistant hypertension (25–50 mg/day of spironolactone)	Hyperkalemia, gynecomastia (spironolactone, not eplerenone)	Weak diuretics Interaction with other K-retaining drugs such as ACE-I, ARBs, beta-blockers and NSAIDs

Contd...

Contd...

Subclass, drug	*Site of action*	*Mechanism of action*	*Clinical uses*	*Toxicities*	*Comments*
Amiloride Triamterene	Collecting tubules	Blocks epithelial sodium channels (ENaC): Reduces Na retention and K wasting	Along with other diuretics to prevent hypokalemia from other diuretics Prevention of amphotericin-induced hypokalemia and hypomagnesemia Reduces lithium-induced polyuria Liddle's syndrome	Hyperkalemia, metabolic acidosis	
Osmotic diuretics					
Mannitol	Multiple segments	Freely filtered at the glomerulus but not reabsorbed by any part of the tubular system. Retains fluid osmotically within the tubular lumen and limit the extent of sodium reabsorption in multiple segments. Marked increase in urine flow, reduced brain volume, decreased intraocular pressure, initial hyponatremia, then hypernatremia	Renal failure due to increased solute load (rhabdomyolysis, chemotherapy), raised intracranial pressure, raised intraocular pressure	Nausea, vomiting, headache	Not used for generalized edema
Carbonic anhydrase inhibitors					
Acetazolamide	Proximal convoluted tubule (PCT)	Indirectly inhibits Na^+-H^+ exchange by reducing the elimination of secreted H^+ in the PCT	Glaucoma, mountain sickness, edema with alkalosis	Hyperchloremic metabolic acidosis, hypokalemia, renal stones may worsen hepatic encephalopathy in cirrhotics	Weak diuretic
Other drugs with diuretic action					
➢ SGLT2 inhibitors—refer to Chapter 12 (Diabetes Mellitus) ➢ Desmopressin, vasopressin (ADH) antagonists—see section on vasopressin receptor antagonists					

LYMPHEDEMA: NONPITTING EDEMA

Characteristics: Edema due to impaired ability of the lymphatic vasculature to collect and transport interstitial fluid, which in the latter stages is characterized by nonpitting edema which does not resolve on limb elevation and is often associated with trophic skin changes such as fibrosis, induration, acanthosis, and warty overgrowths **(Fig. 11.5)**.

Lymphedema may be primary or secondary. It may involve the upper limb or the lower limb.

Classification of primary lymphedema: Based on age at lymphedema onset:
- Lymphedema congenital—at or shortly after birth (<1 year old)
- Lymphedema praecox—from ages 1–35 years
- Lymphedema tarda—>35 years old

Causes of lymphedema:
- Primary causes:
  - Milroy disease
  - Lymphedema-distichiasis syndrome
  - Hypertrichosis–lymphedema–telangiectasia syndrome
  - Yellow nail syndrome: Lymphedema, yellow nail beds, pleural effusion, and bronchiectasis
- Secondary causes:
  - Infections:
    - Filariasis—most common secondary cause worldwide
    - Recurrent bacterial infections
    - Tuberculosis

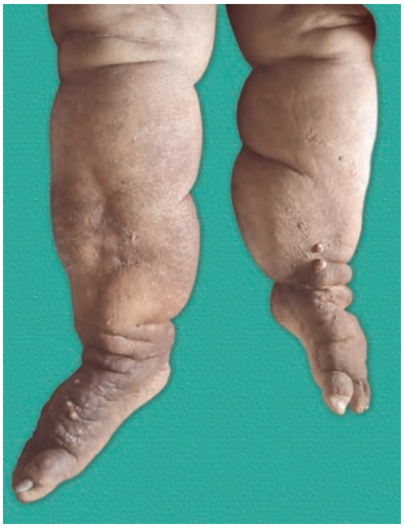

FIG. 11.5: Massive nonpitting edema with elephantiasis caused by filariasis of the leg.

- Malignancy and malignancy-related treatments—most common secondary cause in developed countries:
  - Associated malignancies:
    - Breast cancer—most common
    - Lower extremity melanoma
    - Gynecologic cancer
    - Genitourinary cancer
    - Head and neck cancer
  - Mechanism:
    - Neoplastic disruption of lymphatics
    - Radiotherapy-induced damage to lymphatics
    - Surgical removal of lymph nodes
- Inflammatory disorders:
  - Rheumatoid arthritis
  - Psoriatic arthritis
  - Sarcoidosis
- Circumferential wounds to extremities
- Burns

Clinical features and staging of lymphedema:

- Typically unilateral or asymmetric
- Features of underlying etiology
- The International Society of Lymphology (ISL) provides a staging system for staging lymphedema:
  - Stage 0 or Ia: Usually asymptomatic
  - Stage I: Edema present; edema reduced by limb elevation
  - Stage II:
    - Early stage II: Pitting edema present
    - Late stage II: Nonpitting edema
    - Limb elevation does not reduce edema
  - Stage III: Elephantiasis present with fibrotic changes. Nonpitting edema.
- **Kaposi-Stemmers sign:** The thickened skin folds at the base of the second finger/toe, making it difficult for the examiner to lift the dorsum of the fingers/toes of the affected limb. This can be seen at any stage of the lymphedema.
- Peau d'orange appearance
- Look for scrotal swelling in patients with suspected filariasis.

Complications of Lymphedema

- *Infection*: Recurrent cellulitis, lymphangitis
- Lymphangiosarcoma **(Stewart-Treves syndrome)**

Evaluation

- Blood smear to evaluate for presence of microfilaria
- Radionuclide lymphoscintigraphy (isotope lymphography) is the preferred test if diagnosis is unclear.
- Duplex Doppler ultrasound for examining the deep venous system may supplement the evaluation of extremity edema.
- MRI and CT: Both provide objective evidence of structural changes such as cutaneous thickening, presence of edema within the epifascial plane, and can also detect characteristic "honeycomb" pattern of subcutaneous tissue.

TABLE 11.12: Treatment of lymphedema.

Complex decongestive physiotherapy (CDPT):	*Surgery*:
➢ Manual lymphatic drainage: Mild manual tissue compression ➢ Compression with multilayered bandage wrapping ➢ Skin care ➢ Exercise Weight reduction Limb elevation Diuretics have not been shown to be useful *Control of infection*: ➢ Treatment of cellulitis ➢ An extended period of oral antibiotics may be considered in patients with three or more episodes of cellulitis in a year	➢ Reconstructive surgery: – For early lymphedema – Microsurgical lymphatic-venous anastomosis – Autologous vessel transplantations ➢ Debulking surgery (excisional procedures): – Suction-assisted lipectomy – Staged cutaneous/ subcutaneous excision

Treatment

See **Table 11.12.**

Localized Edema

See **Box 11.1**.

Box 11.1: Various type of localized edema.

- *Facial edema*: Trichinosis, hypothyroidism, allergies, nephrotic syndrome, and angioedema
- *Pretibial myxedema*: Graves' thyrotoxicosis
- *Neurogenic edema*: Secondary to autonomic dysfunction
- *Lipedema*: Adiposity of the legs
- *Pseudothrombophlebitis*: It is unilateral edema with raised venous pressure caused by a popliteal cyst

DISORDERS OF SODIUM BALANCE

Hyponatremia

Q. IM22.5 Enumerate the causes and describe the clinical features and the correct approach to the diagnosis and management of the patient with hyponatremia.

Q. List the causes of drug-induced hyponatremia.

Box 11.2 shows the drugs causing hyponatremia.

Definition: Hyponatremia is defined as a condition in which serum sodium is <135 mEq/L.

- It is a **disorder of water regulation**, i.e., it usually results from increased water retention.
- It is the most common disorder of electrolytes in clinical practice, being reported in 10–30% of acutely or chronically hospitalized patients.

Box 11.2: Drugs causing hyponatremia.

- Vasopressin analogs: Desmopressin, oxytocin
- Medications that stimulate release of vasopressin or potentiate the effects of vasopressin: SSRIs, antidepressants, morphine, and other opioids
- Medications that impair urinary dilution: Thiazide diuretics
- Medications that cause hyponatremia by unknown mechanism: Carbamazepine, antipsychotics, NSAIDs, cyclophosphamide, vincristine, nicotine, and chlorpropamide
- Illicit drugs: Ecstasy (MDMA)—associated with acute, life-threatening hyponatremia

Classification of hyponatremia:

- Based on **duration and rate of development** of hyponatremia:
  - Acute hyponatremia <48 hours
  - Chronic hyponatremia ≥48 hours—more common
- Based on **serum sodium concentration** of hyponatremia:
  - Mild: Serum sodium 130–135 mEq/L
  - Moderate: Serum sodium 125–129 mEq/L
  - Severe: Serum sodium <125 mEq/L
- Based on serum osmolality and volume status, hyponatremia is subdivided into 3 main types **(Fig. 11.6).**

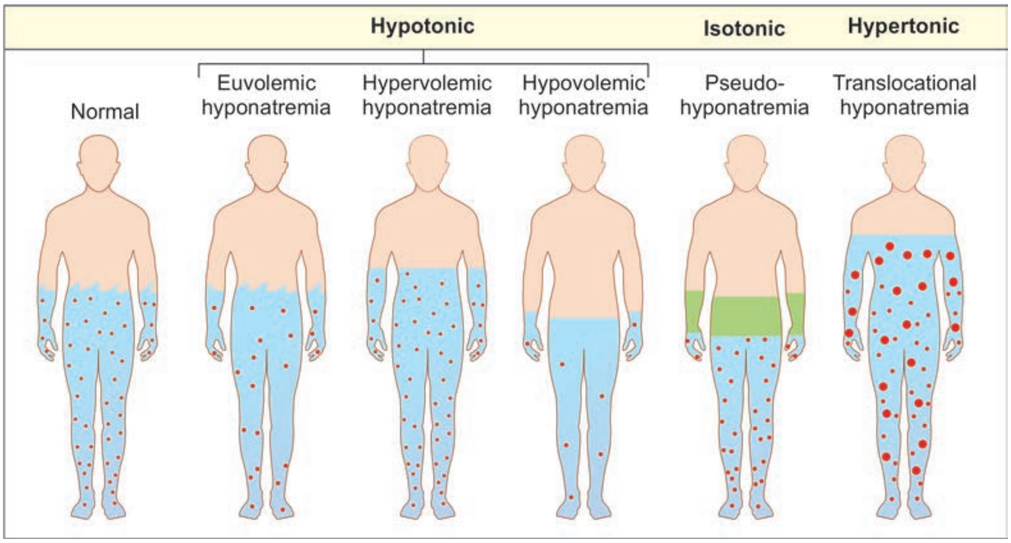

FIG. 11.6: Types of hyponatremia.

Hypotonic Hyponatremia (Box 11.3)

- Serum osmolality < 280 mOsm/kg H_2O
- Most common type of hyponatremia
- Due to:
  - Inadequate solute intake
  - Excess electrolyte-free water intake
  - Retention of electrolyte-free water due to:
    - Presence of AVP
    - Kidney disease
    - Use of diuretics: Diuretics cause volume depletion and release of AVP; and may also lead to diminished sodium transport in renal diluting sites.
- Consequences of hypotonic hyponatremia: Cell edema, predominantly cerebral edema
- Subtypes:
  - Hypovolemic hyponatremia
  - Hypervolemic hyponatremia
  - Euvolemic hyponatremia

Hypovolemic hyponatremia

- Hypovolemic hyponatremia results from loss of fluids rich in sodium and/or potassium.
- This stimulates thirst and AVP secretion, leading to water retention.
- Causes:
  - GI losses:
    - Diarrhea
    - Vomiting
  - Renal losses:
    - Diuretics (predominantly thiazide diuretics)
    - Cerebral salt wasting
    - Adrenal insufficiency
    - Salt-losing nephropathies
  - Dermal losses:
    - Burns
    - Sweating
  - Third spacing:
    - Pancreatitis
    - Sepsis
    - Bowel obstruction

Hypervolemic hyponatremia

- Caused by renal sodium and water retention
- Causes:
  - Cirrhosis of liver
  - Heart failure
  - Chronic kidney disease
  - Nephrotic syndrome

Euvolemic hyponatremia

- Most common dysnatremia in hospitalized patients
- Causes:
  - SIADH
  - Nephrogenic syndrome of inappropriate antidiuresis
    - Due to mutation causing activation of vasopressin receptor 2 (V2R)

Box 11.3: Alternate classification of hypotonic hyponatremia based on the ability to excrete dilute urine.

- Unimpaired urine dilution (ADH levels are not elevated)
  - Primary polydipsia
  - Low dietary solute intake (beer potomania, tea and toast diet)
- Impaired urine dilution but normal suppression of ADH
  - Advanced renal failure
  - Diuretic-induced hyponatremia
- Impaired urine dilution due to unsuppressed ADH secretion
  - Reduced effective arterial blood volume
    - Hypovolemic hyponatremia
    - Heart failure and cirrhosis (hypervolemic hyponatremia)
    - Addison's disease
  - Syndrome of inappropriate antidiuretic hormone secretion (SIADH)
- Disorders with impaired urine dilution due to abnormal V2 receptor (nephrogenic SIADH)
- Abnormally low osmostat which leads to low threshold for release of ADH
- Exercise-induced hyponatremia
- Cerebral salt wasting

- Low solute intake: "tea and toast" diet, beer potomania
- Hypothyroidism
- Glucocorticoid deficiency
- Exercise associated hyponatremia
  - Due to excessive water intake combined with impaired water excretion due to persistent ADH secretion
- Water intoxication.

Isotonic Hyponatremia

- Serum osmolality 280–295 mOsm/kg H_2O
- Pseudohyponatremia due to hyperlipidemia or hypoproteinemia (e.g., multiple myeloma).

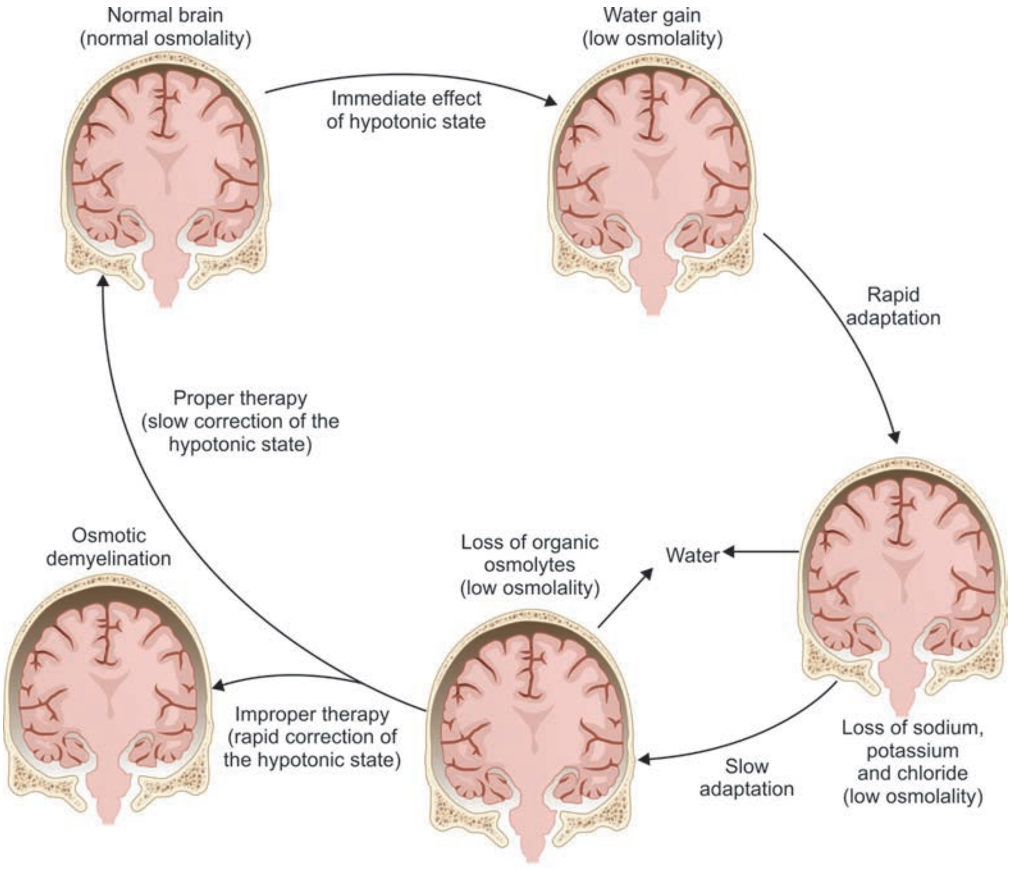
Hypertonic Hyponatremia

- Serum osmolality > 295 mOsm/kg H_2O
- Due to presence of additional osmoles (glucose/mannitol)
- Hyperglycemia
- *Note:* Sodium correction in hyperglycemia: For every 100 mg/dL increase in blood sugar, sodium concentration will fall by approximately 2 mEq/L
- Hypertonic fluid infusion
- Radiocontrast.

Effect of hypotonic hyponatremia on brain (Fig. 11.7)

Hyponatremia induces generalized cellular swelling due to entry of water from ECF to ICF. The symptoms of hyponatremia are primarily neurological and are due to the development of cerebral edema within a rigid skull.

- **Swelling and reduced osmolality:** Within minutes of hyponatremia, the reduced osmolality causes a shift of fluid from the ECF to the ICF, leading to brain swelling. This usually occurs when the hyponatremia develops rapidly.



Normal brain
(normal osmolality)
Immediate effect
of hypotonic state
Water gain
(low osmolality)
Rapid
adaptation
Proper therapy
(slow correction of the
hypotonic state)
Osmotic
demyelination
Loss of organic
osmolytes
(low osmolality)
Water
Improper therapy
(rapid correction of
the hypotonic state)
Slow
adaptation
Loss of sodium,
potassium
and chloride
(low osmolality)

FIG. 11.7: Effects of hyponatremia on the brain.

- **Rapid adaptation:** The brain tries to rapidly adapt to this hypotonic environment by the loss of electrolytes such as sodium, potassium, and chloride. These are osmotically active and help in partially restoring the brain volume.
- **Slow adaptation:** Further loss of osmotically active organic compounds such as glutamate, myoinositol, and taurine from the brain cells also help in restoring brain volume.
- The adaptation process takes about 48 hours, which is the basis for the classification of acute and chronic hyponatremia based on the threshold of 48 hours.
- **Slow versus rapid correction of hypotonicity:**
  - Before adaptation (<48 hours), decreased extracellular osmolality triggers water to enter brain cells, increasing the risk of cerebral edema.
  - After adaptation (>48 hours), rapid increase in serum sodium concentration can cause brain cells to release water, increasing the risk of osmotic demyelination. Hence sodium should be corrected at a slow rate in chronic hyponatremia.

Clinical Features

- Hyponatremia is essentially a laboratory diagnosis.
- History and physical examination should determine the volume status of the patient and try to identify the cause of the hyponatremia.
- Symptoms due to hyponatremia depend on the acuity of presentation and the serum sodium levels, as described in **Table 11.13**.

TABLE 11.13: Classification by severity of symptoms of hyponatremia.

Severity	*Serum sodium level*	*Neurologic symptoms*	*Typical duration of hyponatremia*
Mild	<135 mmol/L	Headache, irritability, difficulty concentrating, altered mood, and depression	Chronic
Moderate	Generally <130 mmol/L	Nausea, confusion, disorientation, altered mental status, unstable gait, and falls	Acute or chronic
Severe	Generally <125 mmol/L	Vomiting, seizures, obtundation, respiratory distress, and coma	Acute

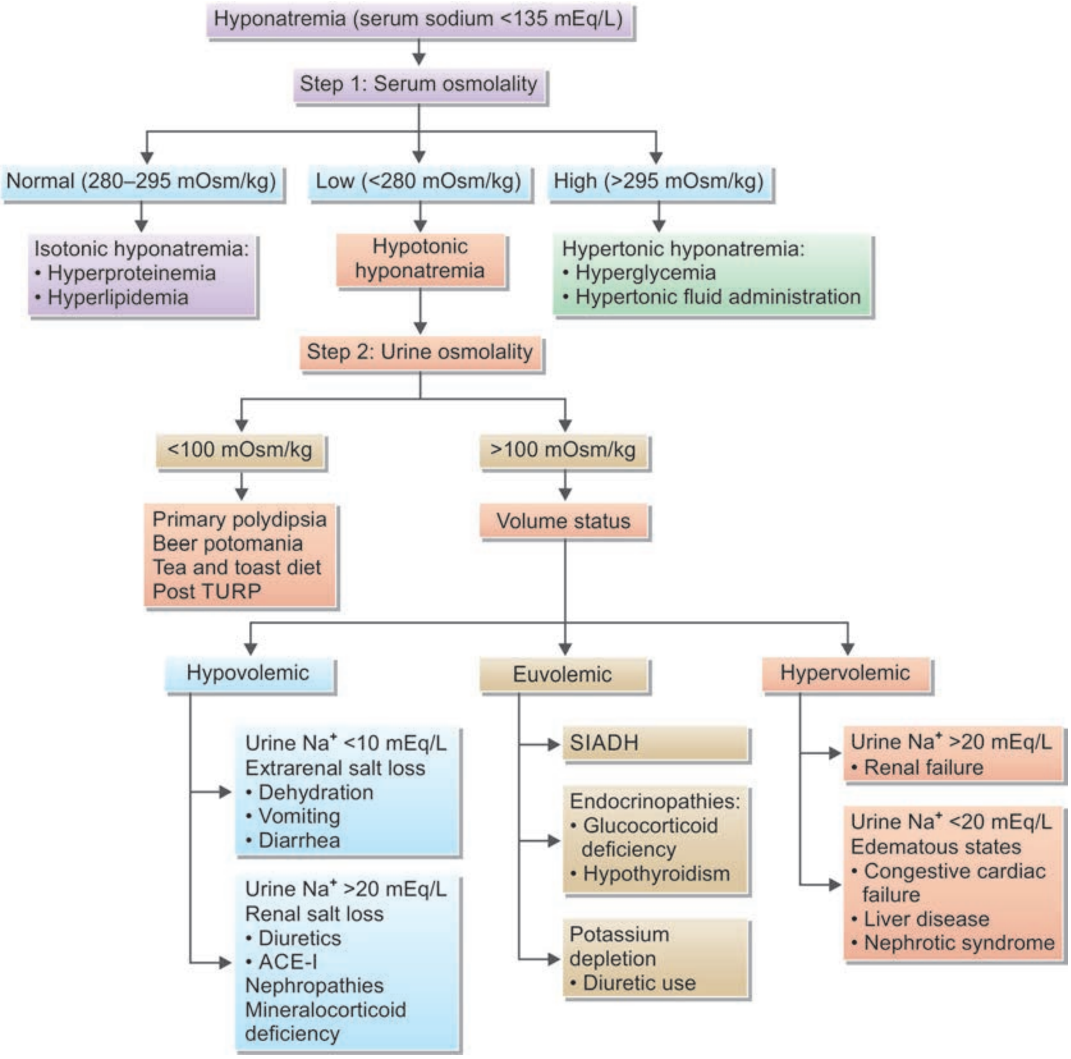
Investigations

- **Step 1: Serum sodium:**
  - Hyponatremia is diagnosed when serum sodium is <135 mEq/L
  - Based on severity, hyponatremia is classified as:
    - Mild: Serum sodium 130–135 mEq/L
    - Moderate: Serum sodium 125–129 mEq/L
    - Severe: Serum sodium < 125 mEq/L
- **Step 2: Serum osmolality:**
  - Serum osmolality < 275 mOsm/kg H_2O indicates hypotonic hyponatremia.
  - Serum osmolality between 280 and 295 mOsm/kg H_2O indicates isotonic hyponatremia (pseudohyponatremia).
  - Serum osmolality > 295 mOsm/kg H_2O indicates hypertonic hyponatremia.
- **Step 3: Urine osmolality:**
  - It should be measured in patients with hypotonic hyponatremia to confirm if urine is appropriately dilute.
  - If urine osmolality is less than 100 mOsm/kg H_2O
    - It indicates that there is no diluting defect.
    - This may be seen in primary polydipsia or due to low solute intake (e.g., beer potomania)
    - Low urine osmolality may also be seen in patients with hypovolemic hyponatremia who have been volume resuscitated, if osmolality is measured after administration of isotonic saline.
- If urine osmolality is more than 200 mOsm/kg H_2O, assess volume status and urine sodium.
- **Step 4: Urine sodium (Table 11.14)**
- **Other investigations:**
  - Thyroid function test: To rule out hypothyroidism
  - Serum cortisol ± ACTH: To exclude adrenal insufficiency
  - Serum creatinine: To look for renal insufficiency
  - Serum uric acid: May help assess volume status
  - Other tests to diagnose the underlying cause, as guided by history and physical examination:
    - Serum lipids and serum protein electrophoresis in cases of pseudohyponatremia to look for hypercholesterolemia and multiple myeloma, respectively.
    - Echocardiogram, BNP: For heart failure

TABLE 11.14: Differentiating hypotonic hyponatremia based on volume status and urine sodium.

Volume status	*Urine sodium (mEq/L)*	*Etiology*
Hypovolemic	≤20	Nonrenal sodium loss
	>20	Renal sodium loss
Hypervolemic	≤20	Cirrhosis, heart failure, and nephrotic syndrome
	>20	Renal failure
Euvolemic	>20	Most patients with euvolemic hyponatremia

FLOWCHART 11.2: Diagnosing the cause of hyponatremia.



Hyponatremia (serum sodium <135 mEq/L)
Step 1: Serum osmolality
Normal (280–295 mOsm/kg)
Low (<280 mOsm/kg)
High (>295 mOsm/kg)
Isotonic hyponatremia:
• Hyperproteinemia
• Hyperlipidemia
Hypotonic hyponatremia
Hypertonic hyponatremia:
• Hyperglycemia
• Hypertonic fluid administration
Step 2: Urine osmolality
<100 mOsm/kg
>100 mOsm/kg
Primary polydipsia
Beer potomania
Tea and toast diet
Post TURP
Volume status
Hypovolemic
Euvolemic
Hypervolemic
Urine Na+ <10 mEq/L
Extrarenal salt loss
• Dehydration
• Vomiting
• Diarrhea
Urine Na+ >20 mEq/L
Renal salt loss
• Diuretics
• ACE-I
Nephropathies
Mineralocorticoid deficiency
SIADH
Endocrinopathies:
• Glucocorticoid deficiency
• Hypothyroidism
Potassium depletion
• Diuretic use
Urine Na+ >20 mEq/L
• Renal failure
Urine Na+ <20 mEq/L
Edematous states
• Congestive cardiac failure
• Liver disease
• Nephrotic syndrome

- Ultrasound abdomen: Cirrhosis
- Urine for proteinuria
- CT brain/chest/abdomen: To help detect paraneoplastic SIADH.

Approach to the diagnosis of the cause of hyponatremia **(Flowchart 11.2).**

Management

The management of hypotonic hyponatremia depends on the severity, duration of symptoms, and the underlying cause.

Goals of treatment

- To correct serum sodium levels to avoid complications of severe hyponatremia
- To avoid overly rapid correction of hyponatremia, which may lead to osmotic demyelination
- Correct underlying causes

1. **Severe symptomatic hyponatremia:**
   - Goal: Rapid increase of serum sodium by 4–6 mEq/L is recommended irrespective of whether hyponatremia is acute or chronic.
   - This is done by IV infusion of hypertonic saline.
     - Protocol 1: 100 mL bolus of 3% saline is infused over 10 minutes; repeated up to 3 times, as necessary.
     - Protocol 2: 150 mL bolus of 3% saline over 20 minutes. Check serum sodium concentration after 20 minutes. Consider repeating twice or until a target of 5 mEq/L increase in serum sodium concentration.

- Follow-up management:
  - If symptoms improve: Stop infusion of hypertonic saline
    - Start treatment based on etiology, if identified
  - If symptoms do not improve:
    - Continue IV infusion of 3% hypertonic saline aiming for an increase in sodium concentration by 1 mmol/L/hr
  - *Note:* Stop hypertonic saline when either:
    - Symptoms improve or
    - Serum sodium concentration increases by 10 mEq/L in total or
    - Serum sodium concentration reaches 130 mEq/L

2. **Mild or asymptomatic hyponatremia:**
   - Treatment depends on whether hyponatremia is acute or chronic and based on the underlying etiology
   - Rate of correction:
     - Acute hyponatremia: Rate of correction does not need to be restricted in well-documented cases of acute hyponatremia
     - Chronic hyponatremia/duration of hyponatremia unknown:
       - Increase serum sodium with a goal of ≤6–8 mEq/L/day and not more than 18 mEq/L in 48 hours
       - Monitor serum sodium every 2–4 hourly
3. **Estimating the effect of 1 L of any IV saline infusion on serum sodium levels:**
   - Change in serum sodium = [(infusion sodium concentration + infusion potassium concentration) – serum sodium concentration/total body water + 1]
   - The sodium content of various intravenous fluids is mentioned in **Table 11.15.**
   - This formula may be used to determine the amount of saline and the rate of fluid infusion required to correct hyponatremia.
   - However, this formula is only a rough guide and is limited by the fact that it does not account for ongoing electrolyte or water losses.
   - Use of this formula does not serve as a replacement for regular serum sodium monitoring. Sodium levels should be monitored every 2–4th hourly.

TABLE 11.15: Sodium content of various intravenous fluids per liter.

Intravenous fluid	***Sodium content***
7.5% $NaHCO_3$	900 mEq/L
3% NaCl	512 mEq/L
0.9% NaCl normal saline	154 mEq/L
Ringer lactate	130 mEq/L
0.45% NaCl Half NS	77 mEq/L
Isolyte G	63 mEq/L
Isolyte M	40 mEq/L
5% Dextrose	Nil

4. **Additional treatment based on the underlying etiology (in mild or asymptomatic disease)**
   a. Hypovolemic hyponatremia:
      - In patients with asymptomatic hypovolemic hyponatremia, isotonic saline can be used to restore the intravascular volume.
      - Amount of 0.9% saline to be replaced may be calculated by the above formula and overcorrection of chronic hyponatremia should be avoided.
      - Fludrocortisone can be used in cerebral salt-wasting syndrome.

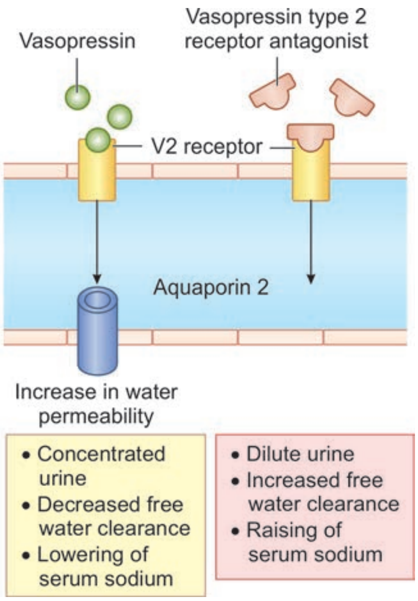
   b. Hypervolemic hyponatremia:
      - Fluid restriction:
        - The amount of fluid intake should be [urine output – 500 mL]
        - Amount of fluid to be restricted can also be determined by calculating the urine: plasma electrolyte ratio (urinary [Na] + [K]/ plasma [Na])
          a. If the ratio is more than 1, then the fluid can be aggressively restricted up to less than 500 mL/day.
          b. For approx 1 then the fluid can be restrict up to 500–700 mL
          c. For ratio less than 1, fluids can be restricted up to 1 L.
        - Loop diuretics
        - Vasopressin antagonists may be useful when the above measures fail (see section on Vaptans below)

   c. Euvolemic hyponatremia:
      - Treat the underlying cause where possible
      - Fluid restriction
      - Loop diuretics
      - Oral salt tablets in patients with SIADH
      - Oral urea tablets in patients with SIADH
      - Demeclocycline in patients with chronic asymptomatic hyponatremia due to SIADH if unresponsive to fluid restriction
      - Vasopressin antagonists
5. **Correction of inadvertent rapid overcorrection of sodium:**
   - Discontinue hypertonic saline/other measures of active sodium correction
   - Infusion of electrolyte free water (e.g., 5% Dextrose)
   - IV desmopressin

Q. Write short note on VAPTANS.

Vasopressin Receptor Antagonists (VAPTANS)

- Nonselective (mixed V1A/V2): *Conivaptan*: Intravenous
- Selective:
  - *V1A selective (V1RA)*: Relcovaptan
  - *V1B selective (V3RA)*: Nelivaptan
  - *V2 selective (V2RA)*: Tolvaptan, lixivaptan, mozavaptan, satavaptan. V2 selective (V2RA) can cause an electrolyte-free aquaresis, reduce urine osmolality and raise serum Na. Their mechanism of action is presented in **Figure 11.8**.
- Tolvaptan and conivaptan are FDA-approved drugs.
- **Tolvaptan**, an oral V2 selective agent, is the most commonly used agent.
  - Indication: Use in euvolemic or hypervolemic hyponatremia (heart failure).
  - Dose:
    - Initially 15 mg/day
    - Maximum 60 mg/day
  - Treatment should be limited to 30 days
  - Monitor serum sodium and volume status
  - Contraindicated in:
    - Hypovolemic hyponatremia
    - Acute hyponatremia and severe symptomatic hyponatremia (urgent need to raise serum sodium levels)
    - Pregnancy
    - Severe liver dysfunction and cirrhosis
- Vaptans are not suitable for hyponatremia due to cerebral salt wasting and psychogenic polydipsia where the ADH level is appropriate.
- Caution: It should **NOT** be used along with hypertonic saline.
- Adverse effects:
  - Thirst 8–16%; dry mouth 4–13%, polyuria
  - Hypernatremia develops in 5%.
  - Rapid correction of serum sodium levels may predispose to osmotic demyelination syndrome.
  - Hyperglycemia
  - GI hemorrhage in cirrhosis



Vasopressin
Vasopressin type 2 receptor antagonist
V2 receptor
Aquaporin 2
Increase in water permeability
• Concentrated urine
• Decreased free water clearance
• Lowering of serum sodium
• Dilute urine
• Increased free water clearance
• Raising of serum sodium

FIG. 11.8: Mechanism of action of vaptans.

Other Uses of Vaptans

- **Polycystic kidney disease:** Polycystin defects may promote cyst development because they increase intracellular cAMP (a second messenger for AVP acting at the V2R), therefore, V2R antagonists may reduce cyst volume.
- **Congenital nephrogenic diabetes insipidus:** Type 2 V2R mutations cause misfolding and interfere with trafficking of the receptor from the endoplasmic reticulum to the cell membrane—VRA can bind to misfolded intracellular V2R and improve transport to the cell membrane.

Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH/SIAD)

Q. Write short note on syndrome of inappropriate antidiuretic hormone secretion.

The syndrome of inappropriate antidiuretic hormone is a disorder of water and sodium balance characterized by hypotonic euvolemic hyponatremia due to impaired free water excretion, which is caused by nonphysiologic secretion of ADH which persists in the absence of an osmotic or hemodynamic stimulus.

Criteria for the diagnosis of SIADH are enlisted in **Box 11.4**. SIADH is the most common cause of hyponatremia.

Plasma levels of arginine vasopressin (AVP) in various types of SIADH are shown in **Box 11.5** and **Figure 11.9**.

Box 11.4: Bartter's criteria for diagnosis of syndrome of inappropriate antidiuretic hormone secretion.

- Hyponatremia
- Serum osmolality <270 mOsm/kg (hypotonic)
- Euvolemia
- Urinary osmolality >100 mOsm/kg of H_2O
- Urinary sodium >30 mEq/L without restricted dietary intake of salt
- Normal renal, cardiac, hepatic, adrenal, pituitary, and thyroid function
- Exclusion of diuretic use

Box 11.5: Five types of SIADH.

Type A: Characterized by unregulated secretion of vasopressin—most common pattern

Type B: Elevated basal secretion of vasopressin despite normal regulation by osmolality

Type C: "Reset osmostat"

Type D: *Nephrogenic SIAD*—undetectable vasopressin (AVP) levels (these patients may have a gain of function mutation of the V$_2$-receptor)

Type E: "Barostat"—altered baroreceptor signaling despite normovolemia. Thus there is a large increase in vasopressin secretion with minor reduction in blood pressure or volume.

Etiology of SIADH

See **Box 11.6.**

Clinical Features

- **Clinical euvolemia:** No edema observed
- Features of hyponatremia, based on the severity of hyponatremia, as described in the earlier section
- Features suggestive of underlying etiology.

Differentiating features of SIADH, cerebral salt wasting (CSW) and diabetes insipidus are presented in **Table 11.16.**

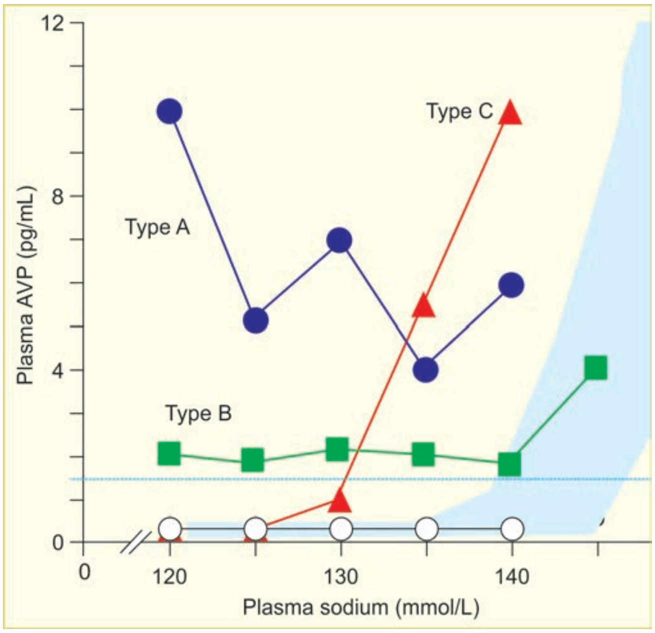


FIG. 11.9: Types of SIADH (syndrome of inappropriate antidiuretic hormone). (AVP: Arginine vasopressin)

Box 11.6: Various causes of SIADH.

- *Malignancies*: Bronchogenic carcinoma (small cell carcinoma), carcinoma of duodenum, stomach, pancreas, prostate, bladder, lymphoma, and mesothelioma
- *Respiratory*: Pneumonia, lung abscess, tuberculosis, aspergillosis, positive pressure ventilation (PPV), pneumothorax, and asthma
- *Neurological*: Encephalitis, meningitis, brain abscess, head trauma, GB syndrome, subarachnoid hemorrhage, subdural hemorrhage, cerebrovascular accident, cerebral and cerebellar atrophy, multiple sclerosis (MS), and hydrocephalus
- *Others:*
  - AIDS
  - *Drugs*: Chlorpropamide, SSRI, MAOI, tricyclic antidepressants, carbamazepine, oxytocin, vasopressin, desmopressin, cyclophosphamide, and vincristine
  - *Acute intermittent porphyria*
  - *Idiopathic*

TABLE 11.16: Differentiating features of syndrome of inappropriate antidiuretic hormone secretion (SIADH), cerebral salt wasting (CSW), and diabetes insipidus.

	SIADH (euvolemic)	***CSW (hypovolemic)***	***Diabetic insipidus***
Mechanism	Inappropriate ADH secretion leading to free water retention	Inappropriate natriuretic peptide levels which leads to salt and water loss	Deficiency/resistance to ADH
Urine output	Normal–low	Normal–high	Polyuria
CVP	Normal	Low	Can be normal or low
Blood pressure	Normal	Orthostatic hypotension may be present	Orthostatic hypotension may be present
Serum Na	Low	Low	High
Serum osmolality	Low <285 mOsm/kg	Low <285 mOsm/kg	Normal or high
Urine Na	High >30 mmol/L	Higher >30 mmol/L	Low
Serum urea	Normal–low	Normal–high	Normal–high
Management	Fluid restriction	Fluid administration	Correction of water deficit, desmopressin

Treatment

- Treat the underlying cause
- In severe hyponatremia, infusion of hypertonic saline as described above
- Restrict the fluid intake to 500–1,000 mL/day, as described above
- Oral salt tablets can be advocated
- Oral urea
- Combination of loop diuretics and oral salt tablets
- Vasopressin-2 receptor antagonists (aquaretics: tolvaptan, conivaptan)
- Demeclocycline:
  - It inhibits AVP in the collecting duct.
  - Indicated for chronic asymptomatic hyponatremia due to SIADH if unresponsive to fluid restriction
  - Adverse effects: Nephrotoxicity

Cerebral Salt Wasting

- ***Causes***:
  - ***Typically described in subarachnoid hemorrhage.***
  - Also seen in other CNS disorders such as closed head injury, CNS surgery, CNS tumors, CNS infections, and meningitis.
- ***Mechanism***: Postulated that brain natriuretic peptide increases urine volume and Na^+ excretion.
- ***Signs/Symptoms***:
  - ***Typical onset is within the first 10 days following a neurosurgical procedure or event.***
  - Polyuria, weight loss, dehydration/hypovolemia, hypotension, and low CVP.

Laboratory Values

- Hyponatremia due to excessive renal Na loss
- High urine Na >30 mmol/L
- Urine osmolality inappropriately elevated >100 mOsm/kg
- Low serum uric acid concentration

Treatment

- 3% saline to raise the serum sodium levels, as described in the section on hyponatremia
- Volume replacement with 0.9% normal saline
- Salt supplementation
- Fludrocortisone

Hypernatremia

Q. IM22.6 Enumerate the causes and describe the clinical and laboratory features and the correct approach to the diagnosis and management of the patient with hypernatremia.

Definition: It is defined as serum Na^+ concentration >145 mmol/L. Hypernatremia is usually the result of loss of water in excess of sodium.

Hypernatremia is generally mild unless thirst mechanism is abnormal or access to water is limited, e.g., infants, physically challenged, impaired mental status, postoperative patient, and intubated patients in ICU.

Table 11.17 describes the causes of hypernatremia based on the volume status.

Classification of Hypernatremia based on Duration of Symptoms

- Acute hypernatremia <48 hours
- Chronic hypernatremia >48 hours

Clinical Features

- Features of underlying etiology
- Features due to hypernatremia:
  - Marked thirst
  - Increased urine frequency/volume
  - Lethargy
  - Weakness
  - Irritability
  - Seizures
    - Coma
    - Neurological symptoms are more common with acute hypernatremia, but patients with chronic hypernatremia may progress to altered mental status and coma
- Volume status should be determined to classify hypernatremia.

Drugs causing hypernatremia

- Drugs associated with nephrogenic DI:
  - Lithium
  - Cisplatin
  - Aminoglycosides
  - Amphotericin B
  - Demeclocycline
  - Vitamins A and D
- Drugs associated with central diabetes insipidus:
  - Phenytoin
  - Ethanol
- Drugs that lead to renal water loss:
  - Loop diuretics
  - Mannitol
- Other drugs:
  - Lactulose and sorbitol—lead to hypotonic GI losses
  - Hypertonic saline
  - Sodium bicarbonate

TABLE 11.17: Causes of hypernatremia based on volume status.

Volume status	*Total body water*	*Total body Na^+*	*Causes*
Hypovolemic	↓↓	↓	**Extrarenal losses:** Diarrhea, fistulas, burns **Renal losses:** Osmotic or loop diuretics, intrinsic renal disease, postobstruction
Euvolemic	↓	Slight ↓/No change	**Renal losses:** Diabetes insipidus, hypodipsia **Extrarenal losses:** Respiratory/skin insensible losses
Hypervolemic	↑	↑↑	➢ Accidental salt ingestion ➢ Administration of hypertonic saline ➢ Malfunctioning of hemodialysis equipment ➢ Primary hyperaldosteronism ➢ Cushing's syndrome

Investigations

- Serum sodium levels: Hypernatremia if serum sodium >145 mEq/L
- 24-hour urine volume measurement:
  - The appropriate response to hypernatremia is a small amount of concentrated urine.
    - Urine volume <800 mL
    - Urine osmolality >800 mOsm/L
    - May be seen in GI or insensible losses, primary hypodipsia
  - Urine volume >1,000 mL suggests a defect in renal water conservation.
- Urine osmolality and serum osmolality: Possible etiologies based on urine osmolality are described in **Table 11.18**.
- Other testing based on etiology:
  - Further testing for DI: Discussed in Chapter 13.
    - Water deprivation test
    - Desmopressin challenge test
    - Serum AVP levels
    - Imaging of the brain with MRI/CT in central DI
      - Renal USG and RFTs: For renal disease
      - Gastric sodium or stool sodium: In salt poisoning
      - CPK: For hypernatremia associated with rhabdomyolysis.

TABLE 11.18: Urine osmolality and the possible etiologies of hypernatremia.

Urine osmolality		*Etiology*
Low	Urine osmolality ≤ serum osmolality	Diabetes insipidus
High	Urine osmolality ≥ serum osmolality	Pure volume depletion not due to diabetes insipidus, e.g., GI or insensible losses, primary hypodipsia
Equal	Urine osmolality = serum osmolality	Partial DI Osmotic diuresis Renal concentrating defect due to renal failure

Management of Hypernatremia

Management depends upon:

- Onset of hypernatremia: Acute vs chronic
- Volume status

Management of chronic hypernatremia

- Fluid replacement:
  - If hypovolemic, treat with 0.9% saline until vital signs are normal.
  - Once patient is euvolemic, calculate the free water deficit as follows:

    Calculation of free water deficit for chronic hypernatremia

    $$\text{Free water deficit} = \frac{\text{Plasma Na}^{+}\text{ concentration} - 140}{140} \times \text{Total body water}$$
  - Also correct ongoing water losses
  - Choice of fluids for correction of free water deficit includes:
    - Water by NG tube or orally
    - IV 5% dextrose
    - Hypotonic saline: IV quarter or half normal saline
  - Goal of treatment: To lower sodium by 8–10 mmol/day
  - Rapid correction of hypernatremia is dangerous because sudden decrease in osmolality can cause rapid shift of water into the cells resulting in swelling of brain cells.
  - Typical requirements of fluids depending on the degree of fluid depletion are mentioned in **Table 11.19**.
- Treatment based on volume status and etiology:
  - Hypovolemic hypernatremia:
    - Correct hypovolemia with isotonic saline
    - Treat underlying cause of hypovolemia (e.g., diarrhea)
    - 5% dextrose or hypotonic saline to correct water deficit
  - Euvolemic hypernatremia:
    - Replace water losses
    - For central DI:
      - Desmopressin

TABLE 11.19: Requirement of fluids depending on degree of depletion.

Degree of depletion	*Type of fluid and route of administration*	*Quantity and time for replacement*
Mild (1–2 L deficit)	Water by mouth or 5% glucose IV	2 L, over 6–12 hours
Moderate (2–4 L deficit)	5% glucose IV	2–4 L, over 24 hours
Severe (4–10 L deficit)	0.9% NaCl IV 5% dextrose IV 5% dextrose IV	1 L, over 1 hour 3 L, over 2 hours 3 L, over 24–48 hours

- For nephrogenic DI:
  - ❑ Stop causative agent
  - ❑ Amiloride for lithium-associated nephrogenic DI
  - ❑ Low sodium diet, combined with thiazide diuretics may be useful. This enhances the proximal reabsorption of salt and water, thus decreasing urinary free water loss
- Hypervolemic hypernatremia:
  - ❑ Discontinue salt intake
  - ❑ Diuretics—to lower serum sodium and treat volume expansion
  - ❑ 5% dextrose to correct water deficit

Management of acute hypernatremia

Correction of serum sodium by 1 mEq/L/hr in the first 6–8 hours is recommended.

Indicators of adequate correction: Relief of thirst, urine output of more than 1,500 mL/24 hours and normal plasma sodium levels.

Diabetes Insipidus

Discussed in Chapter 13.

Osmotic Demyelination Syndrome or Central Pontine Myelinolysis

Q. Write short note on osmotic demyelination.

- It was first described by Adams et al. in 1959.
- *Risk factors*: Alcoholism, chronically ill-patients, elderly/malnourished, cirrhosis predisposes to demyelination (due to depletion of intracellular organic solutes).
- Hypokalemia is a strong predictor.
- Demyelination can be diffuse and not involve the pons. Extrapontine areas include cerebellar and neocortical white/gray junctional areas, thalamus, subthalamus, amygdala, globus pallidus, putamen, caudate, and lateral geniculate bodies.
- Rate of correction over 24 hours more important than rate of correction in any one particular hour.
- More common, if sodium increases by more than 20 mEq/L in 24 hours.
- Very uncommon, if sodium increases by 12 mEq/L or less in 24 hours.
- Symptoms generally occur 2–6 days after elevation of sodium and usually either irreversible or only partially reversible.

Clinical Features

- Dysarthria, dysphagia, parkinsonism, catatonia, locked-in syndrome, lethargy and coma, seizures, nystagmus, ataxia, emotional lability, akinetic mutism, gait disturbance, myoclonus, behavioral disturbances, paraparesis or quadriparesis.
- MRI with diffusion-weighted imaging will be helpful in early detection.

Treatment

- There is no effective therapy.
- Changes are permanent.
- Mortality is very high.
- Case reports of improvement with aggressive plasmapheresis immediately after diagnosis.
- Case reports of treatment with thyrotropin-releasing hormone. Infusion of myoinositol (a major osmolyte lost in the adaptation to hyponatremia) protects against mortality and myelinolysis from rapid correction of hyponatremia.

DISORDERS OF POTASSIUM BALANCE

Potassium

Q. Write short note on the normal physiology of potassium in the body.

- Potassium is the major intracellular cation.
- *Distribution of potassium*:
  - ■ Total body potassium in a person weighing 70 kg is about 4,000 mEq.
  - ■ 99% of the potassium is located inside the cells, predominantly within muscle cells.
    - ♦ 28 L of ICF contains ~4,000 mEq = 150 mEq/L
  - ■ <1% of the total body potassium is extracellular.
    - ♦ 14 L of ECF contains ~70 mEq = 4 mEq/L

- Potassium levels are maintained within a narrow range of 3.5–5.5 mEq/L in the ECF.
- The electrochemical gradient of potassium across the cell membrane is maintained by the Na^+/K^+ ATPase system in the cell membrane which actively transports potassium into and sodium out of the cell.
- This gradient is required for the proper functioning of excitable tissues such as nerves and muscles.
- Overall potassium balance:
  - Normal intake: 100 mEq/day
  - Normal excretion:
    - Urine: 90 mEq/day
    - Fecal excretion: 10 mEq/day
- Internal potassium balance: Sudden changes in plasma K^+ is prevented by:
  - Shift of K^+ into the cell via the Na^+/K^+ ATPase under the influence of insulin and beta-adrenergic stimulation
  - Renal K^+ excretion
- Renal excretion:
  - Excretion through kidney is the major route of elimination of dietary and other sources of excess K^+.
  - Potassium reabsorption:
    - About 65% of filtered potassium is absorbed in proximal convoluted tubule. It is absorbed passively with sodium and water, through the paracellular pathway.
    - 25% of the filtered potassium is reabsorbed at the thick ascending limb by the $Na^+/K^+/2Cl^-$ transporter.
  - Only 10% of the filtered potassium reaches the distal nephron.
  - Potassium secretion (and hence excretion):
    - In the distal nephron and the collecting duct
    - Increased distal fluid and sodium delivery increases K^+ secretion
    - Hyperkalemia and metabolic alkalosis also directly increase K^+ secretion
    - However, the most important factor that influences potassium secretion is aldosterone.
  - A negative feedback mechanism exists between plasma potassium concentration and aldosterone.
  - Hyperkalemia leads to increased release of aldosterone (via renin-angiotensin-aldosterone mechanism or via direct release of aldosterone from adrenal cortex), which then leads to increased K^+ secretion, H^+ secretion, and sodium reabsorption by the kidneys.

Hypokalemia

Q. IM22.7 Enumerate the causes and describe the clinical and laboratory features and the correct approach to the diagnosis and management of the patient with hypokalemia.

- Normal serum potassium level is maintained within a narrow range of 3.5–5.5 mEq/L.
- An abnormally low level (<3.5 mmol/L) of serum potassium (K^+) is called hypokalemia.

Causes (Table 11.20)

TABLE 11.20: Various causes of hypokalemia.

1. **Decreased intake**
   a. Starvation, anorexia nervosa
   b. Potassium-free IV fluid
   c. Clay ingestion (bentonite): It binds dietary K^+ and decreases K^+ absorption
2. **Redistribution into cell**
   a. *Metabolic or respiratory alkalosis*: Due to K^+ redistribution into the cell as well as increased K^+ loss (renal)
   b. Hormonal
      i. Insulin
      ii. β_2 *adrenergic agonist*: It causes K^+ influx into the cell as well as stimulates insulin release
      iii. α-adrenergic antagonist
   c. *Anabolic states*:
      i. Vitamin B12 or folic acid (red blood cell production)
      ii. Granulocyte macrophage colony-stimulating factor
      iii. Total parenteral nutrition
   d. *Others*:
      i. Pseudohypokalemia
      ii. Barium toxicity

   c. **Dialysis and plasmapheresis**
   d. **Renal*:***
      Diuresis:
      i. Diuretics—acetazolamide, loop, and thiazide
      ii. Osmotic diuresis
      iii. Recovery from ATN/renal obstruction
      True mineralocorticoid excess:
      i. Primary hyperaldosteronism (Conn's)
      ii. Secondary hyperaldosteronism
      iii. Cushing syndrome, steroid therapy
      iv. Congenital adrenal hyperplasia
      v. Hereditary glucocorticoid responsive aldosteronism
      vi. Renal artery stenosis
      ***Genetic conditions that cause renal loss of potassium*:**
      i. Liddle syndrome
      ii. Apparent mineralocorticoid excess
      iii. Bartter syndrome
      iv. Gitelman syndrome
      v. Fanconi syndrome

Contd...

Contd...

   - iii. Hypothermia
   - iv. Hypokalemic periodic paralysis
   - v. Chloroquine intoxication

3. **Increased loss**
   - a. **Gastrointestinal**:
     - Vomiting
     - Nasogastric aspiration
     - Diarrhea
     - Villous adenoma
     - VIPoma
     - Ileal loop/conduit with ureteric implants
     - Sodium phosphate solution used for bowel cleansing
     - Laxative abuse
   - b. **Integumentary loss**

***Renal tubular acidosis*:**
- i. Distal (type 1) RTA
- ii. Proximal (type 2) RTA

***Other drugs*:**
- Fludrocortisone
- Antibiotics: Penicillin, ampicillin
- Sodium bicarbonate
- Drugs associated with hypomagnesemia
  - Amphotericin B
  - Aminoglycosides
  - Cisplatin

***Others*:**
- Hypomagnesemia
- Licorice ingestion—mineralocorticoid-like effects

Clinical Features of Hypokalemia

- Severity of clinical manifestations depends on degree and duration of hypokalemia.
- Patients with mild hypokalemia (K^+ 3–3.5 mEq/L) are usually asymptomatic.
- Nervous system manifestations:
  - Leg cramps
  - Generalized weakness
  - Fasciculations and tetany
  - Ascending paralysis including respiratory muscle paralysis
- Cardiac manifestations:
  - Arrhythmias
  - ECG changes
- GI manifestations:
  - Paralytic ileus
- Renal manifestations:
  - Metabolic acidosis
  - Rhabdomyolysis in severe hypokalemia
  - Hypokalemic nephropathy—renal tubular damage
  - Cyst formation
  - Nephrogenic diabetes insipidus
  - Polyuria
- Features of the underlying cause of hypokalemia

Investigations

- Initial tests:
  - Measurement of serum electrolytes, including bicarbonate, calcium, and magnesium.
  - Blood glucose testing
  - Urea and creatinine
  - ECG:
    - **ECG changes (Fig. 11.10 and Table 11.21):** The electrocardiographic changes of hypokalemia are due to delayed ventricular repolarization and do not correlate well with plasma-potassium concentration.
  - Urine potassium
  - Urine potassium to creatinine ratio

TABLE 11.21: Electrocardiographic changes in hypokalemia.

Early changes	***Changes due to severe potassium depletion***
➢ Flattening or inversion of the T wave	➢ Prolonged PR interval
➢ Prominent U wave	➢ Decreased voltage and widening of the QRS complex
➢ ST segment depression	➢ An increased risk of ventricular, arrhythmias especially in patients with myocardial ischemia or left ventricular hypertrophy
➢ Prolonged QU interval	

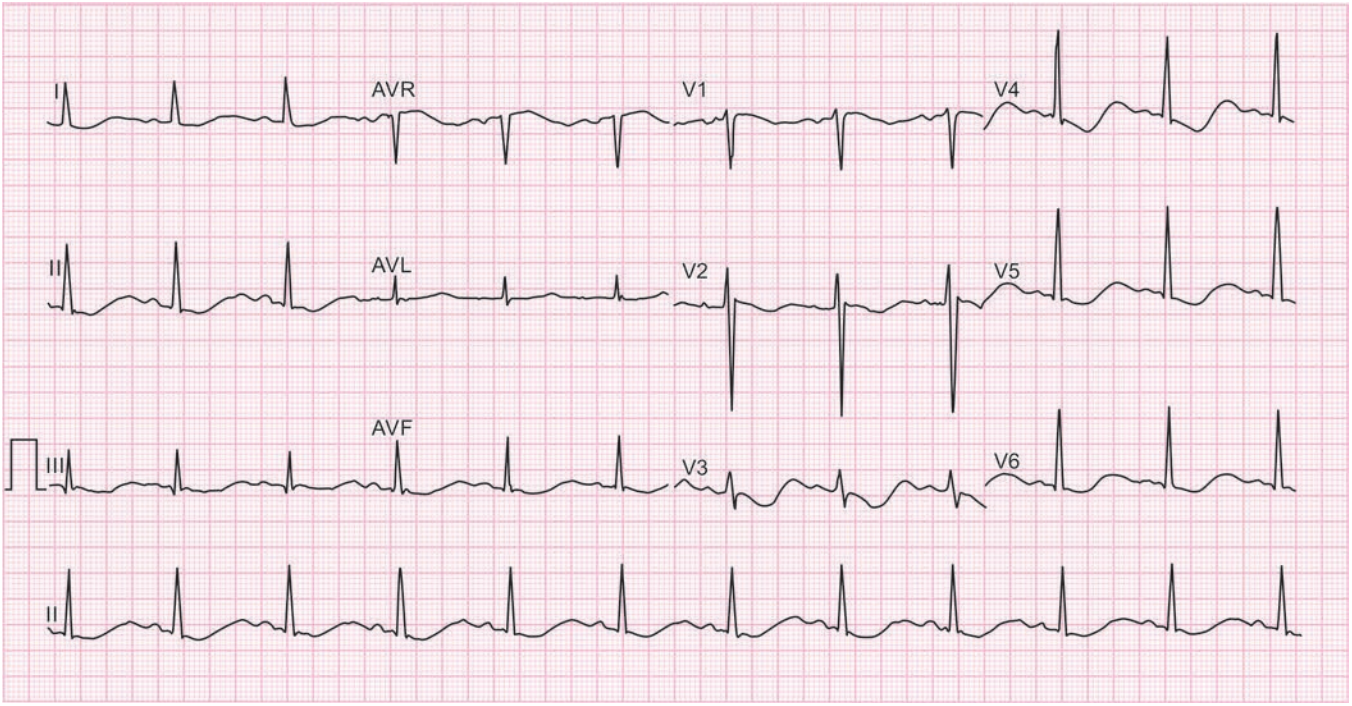

FIG. 11.10: ECG showing QT prolongation and U waves.

Q. Discuss approach to management of hypokalemia. Add a note on TTKG.

Approach to Diagnosis of a Patient with Hypokalemia

- **Exclude pseudohypokalemia and potassium redistribution** from the ECF to the ICF, e.g., with marked leukocytosis (e.g., AML), recent IV insulin, prolonged storage of samples.
- Thorough history and physical examination to determine the etiology, e.g., diuretic and laxative abuse, vomiting, and severity of symptoms.
- In patients with hypokalemic paralysis, life-threatening ventricular arrhythmias or patients with severe hypokalemia who require emergency surgery, emergency treatment should be initiated.
- In the absence of such life-threatening features:
  - Assess intake of potassium. If low, consider oral replacement of potassium
  - If potassium intake is normal, measure urinary K^+ and creatinine.
    - If 24-hour urinary K^+ is less than 15 mEq/day or spot urine K^+/creatinine ratio is less than 15 mEq/g, it suggests extrarenal potassium loss, such as GI potassium loss.
    - If 24-hour urinary K^+ is more than 15 mEq/day or spot urine K^+/creatinine ratio is more than 15 mEq/g, it suggests abnormal renal potassium loss.
  - If renal loss is present, the next step is to assess the **transtubular potassium gradient (TTKG)**.
    - TTKG is a measurement of net K^+ secretion by the collecting duct after correcting for changes in urine osmolality.
    - TTKG = Urinary K^+ × Plasma osmolality/Serum K^+ × Urinary osmolality
    - In hypokalemia, TTKG should be <3
    - TTKG >4 suggests increased distal K^+ secretion.
  - The next step would be to assess the **blood pressure and the volume status**.
    - If hypertension is found, then measure plasma renin, aldosterone, and cortisol levels **(Table 11.22)**
    - If no hypertension is found, look for acid-base status.
  - If **metabolic acidosis** is present, causes include:
    - Renal tubular acidosis

TABLE 11.22: Differentiating hypokalemia with increased distal K^+ secretion and hypertension.

Plasma aldosterone	*Plasma renin*	*Cortisol levels*	*Etiology*
High	High	Normal	Renal artery stenosis Reninoma Malignant hypertension
High	Low	Normal	Primary hyperaldosteronism
Low	Low–normal	Normal	Liddle syndrome Licorice ingestion
Low	Low–normal	High	Cushing syndrome

        - Diabetic ketoacidosis or
        - Acetazolamide use
    - If **metabolic alkalosis** is present:
        - Measure **urine chloride** levels.
            - If urine chloride is <10 mmol/L, consider chloride secreting diarrhea or vomiting
            - If urine chloride is >20 mmol/L, measure urine calcium to creatinine ratio
                - Urine calcium to creatinine ratio <0.15: Gitelman syndrome or thiazide diuretic use
                - Urine calcium to creatinine ratio > 0.20: Bartter's syndrome or loop diuretic use

Additional testing

- Serum digoxin levels if patient is receiving treatment with digoxin
- Thyroid function tests, especially in patients with paralysis, to rule out thyrotoxic periodic paralysis
- Serum magnesium levels, as hypomagnesemia is often associated with hypokalemia, and such patients are often refractory to K^+ replacement alone.
- Other testing as per etiology (e.g., CT of adrenal glands if mineralocorticoid/glucocorticoid/catecholamine excess is suspected).

Treatment

- Therapeutic goals:
    - To correct the potassium deficit
    - To minimize the ongoing losses
    - To treat the underlying cause to prevent further episodes
    - To prevent overly rapid correction, which can cause acute hyperkalemia, which in turn can cause ventricular fibrillation and sudden death
- It should be noted that a decrement of 1 mmol/L in the plasma-potassium concentration (from 4.0 to 3.0 mmol/L) may represent a total body potassium deficit of 200–400 mmol.

Oral Therapy

- Oral or enteral therapy is preferred in nonemergent patients who can take orally and has normal GI tract function.
- Potassium chloride (15 mL = 20 mEq) is the preferred agent. Especially useful in Cl–responsive metabolic alkalosis.
- Potassium phosphate is useful when coexistent phosphorus deficiency.
- Potassium bicarbonate, acetate, gluconate, or citrate is useful in metabolic acidosis.
- Usual dose: 40–100 mEq/day in 2–4 divided doses

IV Therapy

- Indicated for patients with severe hypokalemia (<2.5 mEq/L), symptomatic hypokalemia, those with nonfunctioning GI tract or those who are unable to take orally.
    - *Note:* 1 mL of 15% potassium chloride = 2 mEq/L, 10 mL = 20 mEq/L.
- The maximum concentration of administered potassium should be no more than:
    - 40 mEq/L via a peripheral vein or
    - 100 mEq/L via central vein
- The rate of infusion should not exceed 10–20 mEq/hr unless paralysis or malignant ventricular arrhythmia is present.
    - Maximum rate of infusion should not exceed 40 mEq/hr in these cases.
    - Maximum dose per day: 240–400 mEq/day

Choice of fluid during IV therapy

- KCL should always be administered in saline solutions, rather than dextrose-containing solutions.
- This is because dextrose-containing solutions can stimulate cellular potassium uptake, resulting in worsening of the hypokalemia.

Choice of central line placement for IV therapy

In cases of infusion of potassium chloride through central lines, femoral lines are preferred to internal jugular or subclavian central lines, as the infusion through the latter can lead to rapid changes in the local concentration of potassium and affect cardiac conduction.

Monitoring during IV therapy

- Continuous ECG monitoring should be done, especially if the rate of infusion is more than 10 mEq/hr.
- Serum potassium levels should be monitored 1–4 hours after a dose of 60–80 mEq/L is given, before giving further potassium doses.

Additional therapy

- **Replace magnesium, if magnesium deficiency is present.**
- High potassium diet
- Treat the underlying cause

Hyperkalemia

Q. IM22.8 Enumerate the causes and describe the clinical and laboratory features and the correct approach to the diagnosis and management of the patient with hyperkalemia.

Q. Write short essay/note on:

- **ECG changes in hyperkalemia.**
- **Clinical features, diagnosis, and treatment/management of hyperkalemia.**
- **Drugs used to treat hyperkalemia.**

Definition: Hyperkalemia is defined as plasma **potassium greater than 5.5 mEq/L.**

Based on severity, it may be classified as:

- Mild hyperkalemia: Serum potassium: 5.5–5.9 mEq/L
- Moderate hyperkalemia: Serum potassium: 5.9–6.4 mEq/L
- Severe hyperkalemia: Serum potassium: ≥6.5 mEq/L

Causes of Hyperkalemia

See **Table 11.23.**

TABLE 11.23: Causes of hyperkalemia.

A. *Increased potassium intake*
  - Diet
  - Potassium-containing salt substitutes
  - Potassium supplementation
  - Chewing and ingestion of burnt match heads (cautopyreiophagia)

B. *Decreased renal excretion*
  i. Reduced GFR:
    - Acute kidney injury (AKI)
    - Chronic kidney disease (CKD)

  ii. Tubulointerstitial disease:
    - Interstitial nephritis
    - Sickle cell disease
    - Obstructive uropathy

  iii. Mineralocorticoid deficiency:
    - Primary adrenal insufficiency
    - Type IV RTA

  iv. Drugs:
    - Reduced renin release:
      - Beta-blockers
      - NSAIDs
    - Reduced mineralocorticoid receptor activation:
      - ACE-I
      - ARBs
      - Aldosterone receptor antagonists
      - Heparin
      - Ketoconazole
    - Inhibition of Na^+/K^+ ATPase, necessary for collecting duct K^+ secretion:
      - Calcineurin inhibitors
      - Digitalis
    - Blocking ENaC Na channel, decreasing gradient for K^+ secretion:
      - Amiloride
      - Triamterene
      - Trimethoprim
      - Pentamidine

  v. Other: Gordon syndrome (pseudohypoaldosteronism type 2)

C. *Transcellular shift of potassium*:
  - Metabolic acidosis
  - Severe hyperglycemia
  - Insulin deficiency
  - Beta-blockers
  - Hemolysis
  - Rhabdomyolysis
  - Tumor lysis syndrome
  - Hyperkalemic periodic paralysis

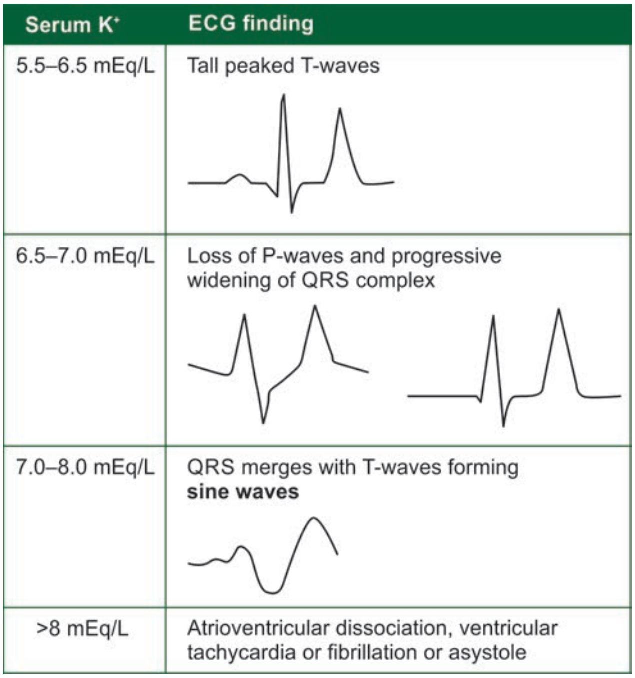
D. *Pseudohyperkalemia:*
  - Hemolysis due to mechanical trauma during venipuncture
  - Repeated fist clenching during blood withdrawal
  - Acute respiratory alkalosis (crying/hyperventilation during blood withdrawal)
  - In vitro hemolysis
  - Leukocytosis

Clinical Features

- **Often asymptomatic** until plasma K^+ concentration is greater than 6.5–7.0 mEq/L, when it may lead to fatal cardiac arrhythmia, hence it is called as **silent killer**. Hence, suspect hyperkalemia as potential cause in all patients presenting with cardiac arrest.
- Signs and symptoms of underlying disease: For example:
  - Chronic kidney disease (CKD)
  - History of drugs causing hyperkalemia
- Signs and symptoms due to hyperkalemia:
  - Cardiac: Arrhythmias **(Figs. 11.11 and 11.12)**
  - Musculoskeletal:
    - Weakness
    - Paresthesia
    - Ascending paralysis
  - Gastrointestinal:
    - Nausea
    - Vomiting
    - Diarrhea

Investigations

- Initial tests:
  - Measurement of urea, creatinine, electrolytes, including bicarbonate
  - Blood glucose levels
  - Blood gas analysis to look for metabolic acidosis
  - ECG: ECG changes are shown in **Figures 11.12 and 11.13.** The earliest electrocardiographic changes are increased T-wave, amplitude or peaked T-wave.
  - Urine electrolytes



Serum K^+	ECG finding
5.5–6.5 mEq/L	Tall peaked T-waves
6.5–7.0 mEq/L	Loss of P-waves and progressive widening of QRS complex
7.0–8.0 mEq/L	QRS merges with T-waves forming **sine waves**
>8 mEq/L	Atrioventricular dissociation, ventricular tachycardia or fibrillation or asystole

FIG. 11.12B: ECG of severe hyperkalemia showing sine wave pattern.

- Additional tests:
    - CPK levels in suspected rhabdomyolysis
    - LDH levels in suspected hemolysis
    - Uric acid and phosphorous levels in suspected tumor lysis syndrome
    - Plasma cortisol, renin and aldosterone levels to assess mineralocorticoid deficiency
    - Serum digoxin levels in patients receiving digoxin

Approach

- Rule out pseudohyperkalemia, transcellular shifts and excess intake of potassium
- Thorough history and physical examination to determine the etiology (e.g., renal disease, drugs) and severity of symptoms
- In asymptomatic patients with serum potassium >6.5 mEq/L or those with hyperkalemia and additional ECG changes/muscle weakness/paralysis or significant tissue injury, emergency treatment should be initiated **(Table 11.30)**.
- **Urine K^+** less than 40 mEq/day suggests reduced renal excretion.
- Urine Na^+ less than 25 mEq/day suggests that distal sodium delivery is a limiting factor in potassium excretion. Volume correction with normal saline or treatment with furosemide may be effective in reducing potassium levels.
- Measurement of **transtubular potassium gradient (TTKG)** helps to determine whether hyperkalemia is caused by aldosterone deficiency/resistance or whether hyperkalemia is secondary to nonrenal cause.
    i. TTKG = Urinary K^+ × Plasma osmolality/Serum K^+ × Urinary osmolality
    ii. Normally expected in the presence of hyperkalemia: 6–12
    iii. If <5: Suggests reduced distal potassium secretion
    iv. If >8–10: Suggests reduced tubular flow
- In cases of hypokalemia due to reduced distal potassium secretion, 0.05 g of 9α-fludrocortisone is given:
    - If TTKG < 8, it suggests tubular resistance. Likely causes include:
        - Tubulointerstitial diseases
        - Urinary tract obstruction
        - Pseudohypoaldosteronism type 1 or 2
        - Drugs: Amiloride, triamterene, spironolactone, calcineurin inhibitors, and trimethoprim
    - If TTKG > 8–10, hypoaldosteronism is likely
- In cases of hypoaldosteronism, renin levels should be measured:
    i. Renin high: Primary adrenal insufficiency, isolated aldosterone deficiency, ACE-I, and ARB
    ii. Renin low: Pseudohypoaldosteronism type 2, acute glomerulonephritis, diabetes mellitus, and beta-blockers, and NSAIDs.

Treatment

The urgency and aggressiveness of treatment of hyperkalemia depends on its degree and clinical status.

Emergency treatment (Table 11.24)

Indications for emergency treatment:

- Asymptomatic potentially fatal hyperkalemia (serum potassium >6.5 mEq/L)
- Profound weakness including paralysis
- Absence of P wave, QRS widening or ventricular arrhythmia on ECG

TABLE 11.24: Drugs used in the emergency treatment of hyperkalemia.

Mechanism	***Intervention***	***Dose***	***Onset and duration***	***Caution***
Myocardial membrane stabilization, if ECG changes are present	IV calcium gluconate or IV calcium chloride	➢ 10 mL of 10% calcium gluconate over 10 minutes ➢ Equivalent elemental calcium dose of 13.6 mEq	➢ Onset: 1–3 minutes ➢ Duration: 30–60 minutes	➢ Should not be administered in $NaHCO_3$ containing solutions because precipitation of calcium carbonate can occur ➢ Hypercalcemia can precipitate digoxin toxicity. Hence should be administered over 30 minutes in patients on digoxin
Intracellular potassium shifting	Dextrose/Insulin	Insulin (regular) 10 units intravenous with 50 mL of 50% dextrose, if blood glucose < 250 mg/dL	➢ Onset: 30 minutes ➢ Duration: 4–6 hours	Watch for hypoglycemia
	Beta agonists	➢ Nebulized salbutamol 10 mg ➢ Note that the dose of salbutamol is 2–8 times that usually given for bronchodilation	➢ Onset: 30 minutes ➢ Duration: 2–4 hours	Tachycardia
Potassium removal	Sodium polystyrene sulfonate	30–60 g PO or PR	➢ Onset: 1–2 hours ➢ Duration: 4–6 hours	Risk of colon perforation when given as enema, especially with concurrent use of sorbitol
	Hemodialysis	Best way of removal	➢ Onset: Immediate ➢ Duration: Until dialysis completed	Serum potassium should not be reduced too rapidly in patients with arrhythmias or heart disease

Other drugs which can be considered in acute hyperkalemia:

- **Sodium bicarbonate:**
  - Useful in patients who have metabolic acidosis (pH <7.2)
  - Mechanism: Shifts potassium into the cell
  - Adverse effects:
    - Can worsen intravascular volume overload, especially in patients with oliguric AKI
    - Acute hypernatremia
- IV normal saline: Mechanism: Increases distal sodium delivery, thus helping in renal excretion.
- Diuretics:
  - Useful for chronic or mild hyperkalemia
  - Used in volume expanded patients or along with IV normal saline
  - Mechanism: Increased renal excretion
  - Not very effective in patients with severe renal impairment, who constitute the majority of the population with severe hyperkalemia.
    - Hence, it is not used routinely in the emergency management of hyperkalemia.

Chronic treatment

- Treat the underlying cause
- Stop the offending drug
- Reduction of dietary potassium intake
- Use of medications such as:
  - Diuretics
  - Sodium bicarbonate in patients with acidosis
  - Potassium-binding resins
- Sodium polystyrene sulfonate (SPS), patiromer, and sodium zirconium cyclosilicate (ZS-9)
  - Fludrocortisone has been used in patients with chronic hypotension secondary to adrenal insufficiency in patients with normal renal function.

ACID-BASE BALANCE

Definitions

- **Acid:** Any compound which forms H^+ ions in solution (proton donors), e.g., carbonic acid releases H^+ ions.
- **Base:** Any compound which combines with H^+ ions in solution (proton acceptors), e.g., bicarbonate (HCO^-) accepts H^+ ions.

Regulation of Acid-base Balance

- Maintenance of blood pH is an important homeostatic mechanism of the body. The pH of the blood is maintained between 7.35 and 7.45.
- Normal pH and its variation is indicated in **Box 11.7**.

Maintenance of Acid-base Balance/pH

Many physiological mechanisms maintain pH of the ECF within narrow limits **(Box 11.8)**.

Q. IM22.13 **Identify the underlying acid-based disorder based on an ABG report and clinical situation.**

Box 11.7: Normal pH and its variation.

- *Normal pH*: 7.35–7.45
- *Acidosis*: Physiological state resulting from abnormally low plasma pH
- *Alkalosis*: Physiological state resulting from abnormally high plasma pH
- *Acidemia*: Plasma pH <7.35
- *Alkalemia*: Plasma pH >7.45
- *When we interpret an ABG, 7.4* is taken as normal pH. Less than 7.4 is taken as acidemia, more than 7.4 is taken as alkalemia.

Box 11.8: Response of the body to acid-base challenge.

1. *Buffering*: Two most common chemical buffer groups:
   i. Bicarbonate
   ii. Nonbicarbonate (hemoglobin, protein, and phosphate):
      - Blood buffer systems act instantaneously
      - Regulate pH by binding or releasing H^+
2. Respiratory acid-base control mechanisms
3. Renal acid-base control mechanisms

APPROACH TO ACID-BASE DISORDER

Step 1: Determine if the patient has academia (plasma pH <7.35) or alkalemia (plasma pH > 7.45).
Step 2: Determine the primary abnormality and the compensatory response, as described in **Table 11.25**.
Step 3: Determine whether the compensation is appropriate, as describe in **Box 11.9**. If the compensation is **not** appropriate, it suggests the presence of a combined acid-base disorder.

TABLE 11.25: Classification of acid-base disorders.

Disorder	*pH*	*[H^+]*	*Primary abnormality*	*Compensatory response*
Metabolic acidosis	↓	↑	↓ [HCO_3] <22 mmol/L	↓ pCO_2
Metabolic alkalosis	↑	↓	↑ [HCO_3] >26 mmol/L	↑ pCO_2
Respiratory acidosis	↓	↑	↑ pCO_2 >42 mm Hg	↑ [HCO_3]
Respiratory alkalosis	↑	↓	↓ pCO_2 <38 mm Hg	↓ [HCO_3]

- For example:
  - In a patient with metabolic acidosis, the body tries to compensate by lowering the pCO_2.
    - If the pCO_2 is lower than expected: Compensation is excessive. The patient has an additional respiratory alkalosis.
    - If the pCO_2 is higher than expected: Compensation is inadequate. The patient has an additional respiratory acidosis.

Step 4: For patients with metabolic acidosis:
- Determine anion gap.
- Assess the delta ratio.

Classification of Acid-Base Disorders

See **Table 11.25.**

ANION GAP

Q. What is anion gap? Enumerate conditions associated with increased anion gap.

- Anion gap (AG) denotes the concentration of the unmeasured anions in the plasma, namely—phosphates, sulfates, organic acids, and protein anions.
- Anion gap = {[Na^+] + [K^+]} – {[HCO_3^-] + [Cl^-]}
  - Normal cations in plasma: Na^+, K^+, Ca^{2+}, Mg^{2+}
  - Normal anions in plasma are Cl^-, HCO^-, negative charges present on albumin, phosphate, sulfate, lactate, and other organic acids.
  - The sums of the positive and negative charges are equal.
- Normal anionic gap is 8–12 mEq/L.
- **Albumin is the principal unmeasured anion.**
- Hence, if there are gross changes in serum albumin levels, the following correction should be applied.
  - $AG_{corrected} = AG + \{(4 - \text{albumin}) \times 2.5\}$
- Elevated anion gap:
  - An elevated anion gap suggests the presence of metabolic acidosis with a circulating anion
  - Usually found in some forms of metabolic acidosis **(Table 11.26)**.

Box 11.9: Determining if the compensation is appropriate.

Expected compensation

Metabolic acidosis:
- *Winter's formula*: $pCO_2 = 1.5\,[HCO_3] + 8 \pm 2$
- *Alternate methods*:
  - For decrease of 1 mmol/L of HCO_3^-: 1.2 mm Hg decrease in pCO_2 **or**
  - $pCO_2 = HCO_3^- + 15$ **or**
  - pCO_2 = Last 2 digits of pH
- *Note:* If pCO_2 > expected pCO_2 • additional respiratory acidosis
- If pCO_2 < expected pCO_2 • additional respiratory alkalosis is also present.

Metabolic alkalosis:
- For every 10 mmol/L increase in HCO_3 • pCO_2 increases by 7
- *Note:* If pCO_2 > expected pCO_2 • additional respiratory acidosis
- If pCO_2 < expected pCO_2 • additional respiratory alkalosis is also present

Respiratory acidosis:
- ***Acute*:** For every 10 increase in pCO_2 • HCO_3 increases by **1**
- ***Chronic*:** For every 10 increase in pCO_2 • HCO_3 increases by **3.5**
- *Note:* If HCO_2^- > expected HCO_2^- • additional metabolic alkalosis is also present
- If HCO_2^- < expected HCO_2^- • additional metabolic acidosis is also

Respiratory alkalosis:
- ***Acute*:** For every 10 decrease in pCO_2 • HCO_3 decreases by **2**
- ***Chronic*:** For every 10 decrease in pCO_2 • HCO_3 decreases by **5**
- *Note:* If HCO_2^- > expected HCO_2^- • additional metabolic alkalosis is also present
- If HCO_2^- < expected HCO_2^- • additional metabolic acidosis is also present.

TABLE 11.26: Causes of high anion gap metabolic acidosis (HAGMA).

Lactic acidosis	**Toxins**	Mnemonic: **GOLDMARK**
Ketoacidosis:	Ethylene glycol	**G**—Glycols
Diabetic	Methanol	**O**—Oxoproline
Alcoholic	Salicylates (Aspirin)	**L**—L-Lactate
Starvation	Propylene glycol	**D**—D-Lactate
Renal failure		**M**—Methanol
(acute and chronic)		**A**—Aspirin
		R—Renal failure
		K—Ketoacidosis

- Normal anion gap: Normal anion gap metabolic acidosis can result from renal or nonrenal causes **(Table 11.27)**.
- **Urinary anion gap (UAG):**
  - UAG *(in mEq/L or mmol/L)* = ($U_{Na}^+ + U_k^+$)
  - In cases of normal anion gap metabolic acidosis (NAGMA), urine anion gap is useful to distinguish between renal and extrarenal causes.
  - UAG is normally a positive value: +30 to +50 mmol/L.

TABLE 11.27: Causes of normal anion gap metabolic acidosis(NAGMA).

Loss of bicarbonate	*Reduced renal acid excretion (retention of HCl)*	*Others*
➢ GI causes: Diarrhea, biliary or pancreatic fistulas ➢ Renal causes: – Proximal renal tubular acidosis (type 2) – Toluene intoxication (>12 hours) – Carbonic anhydrase inhibitors – Spironolactone ➢ Ureter: GI connections (intestinal mucosa exchanges urinary chloride for bicarbonate resulting in urinary bicarbonate loss)	➢ Renal failure ➢ Renal tubular acidosis type 1 (distal) and type 4	➢ Fluid resuscitation with saline (mild dilution of HCO_3^- by addition of Cl^- containing fluid) ➢ Adrenal insufficiency ➢ Drugs: – Prostaglandin inhibitors – Amiloride – Trimethoprim – Pentamidine

- Positive UAG:
  - Renal tubular acidosis (types 1, 2, and 4)
  - Renal failure
- Negative UAG: Increased renal excretion of an unmeasured cation such as NH_4^+:
  - Diarrhea
  - Biliary or pancreatic fistulas
  - GI-ureteral connections

"Delta Ratio"/"GAP-GAP"

- Ratio of delta anion gap (difference in anionic gap from the normal anion gap) to delta bicarbonate (the difference in bicarbonate from the normal bicarbonate levels).
- Delta ratio = Δ AG/Δ HCO_3^-
- It can be used to identify concurrent metabolic disorders.
- Should be applied when there is high anion gap metabolic acidosis
- Interpretation of delta ratio:
  - 0.8–1.2 = Anion gap metabolic acidosis alone
  - 0.3–0.7 = Anion gap metabolic acidosis + Nonanion gap metabolic acidosis
  - >1.2 = Anion gap metabolic acidosis + Metabolic alkalosis

Metabolic Acidosis

Q. IM22.9 Enumerate the causes and describe the clinical and laboratory features of metabolic acidosis.

Q. Write short note on:

- Causes of metabolic acidosis (Refer Tables 11.27 and 11.28).
- Clinical features and management of metabolic acidosis.

- Metabolic acidosis is a primary acid-base disorder characterized by fall in both pH of blood (↓ pH) and bicarbonate level in the plasma (↓ HCO_3^-).
- Metabolic acidosis can develop when there is an imbalance between net acid production and net acid excretion **(Fig. 11.13).**
- Metabolic acidosis occurs when an acid other than carbonic acid (due to CO_2 retention) accumulates in the body, leading to fall in the plasma bicarbonate.
- Thus, it is due to gain of strong acid or loss of base (HCO_3^-).

Clinical Features (Box 11.10)

Symptoms are specific and a result of the underlying pathology.

Treatment

- Correct the underlying disorder
- Sodium bicarbonate may be administered in severe acidosis.
- Tromethamine (tris-hydroxymethyl aminomethane; THAM) is an alternative to $NaHCO_3$.
- Dialysis may be necessary in renal failure with metabolic acidosis.

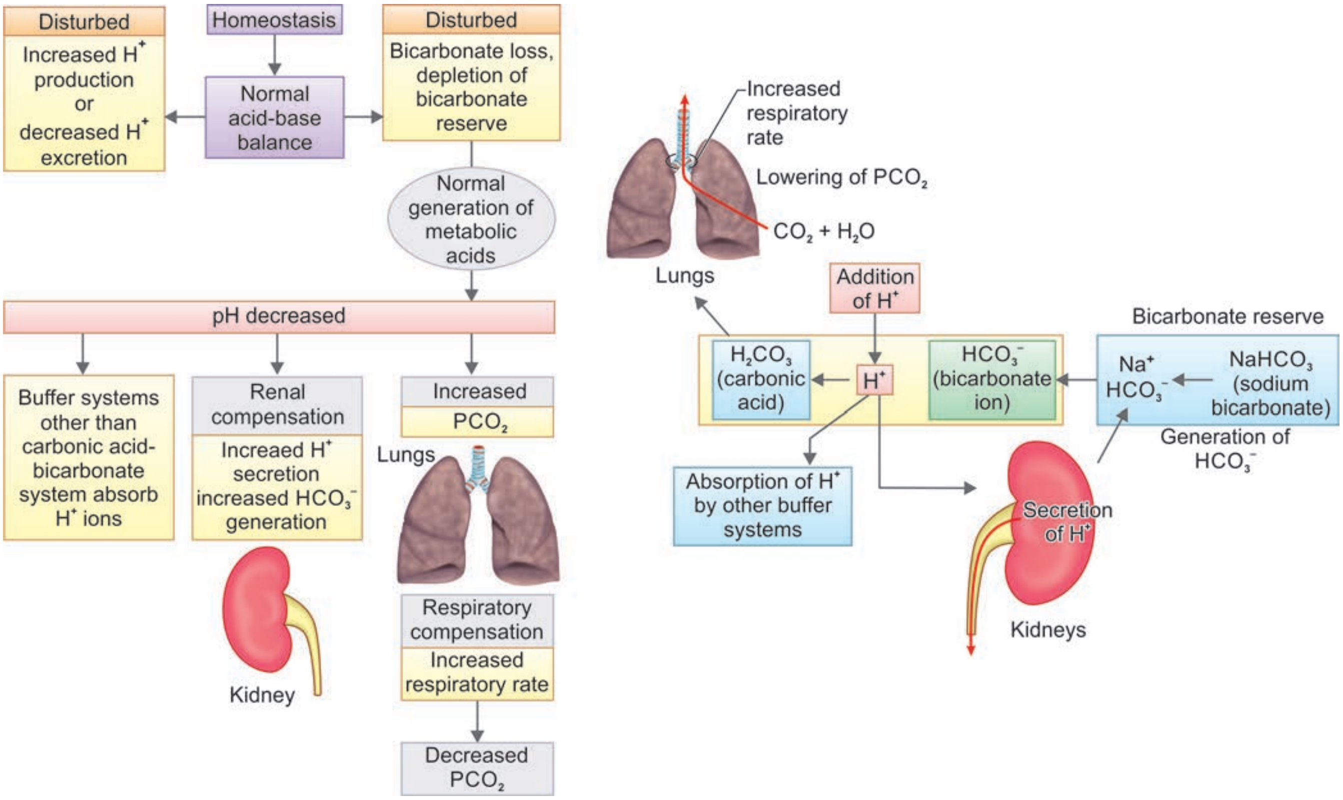
Box 11.10: Clinical features of metabolic acidosis.

Respiratory effects: Hyperventilation. In severe cases, there is deep sighing respiration (Kussmaul's breathing or "air hunger").

CVS: ↓ myocardial contractility, sympathetic over activity, resistant to catecholamines

CNS: Lethargy, disorientation, stupor, muscle twitching, coma, and cranial nerve palsies

Others: Hyperkalemia



Disturbed
Increased H+ production or decreased H+ excretion
Homeostasis
Normal acid-base balance
Disturbed
Bicarbonate loss, depletion of bicarbonate reserve
Normal generation of metabolic acids
pH decreased
Buffer systems other than carbonic acid-bicarbonate system absorb H+ ions
Renal compensation

Bicarbonate reserve
Na+ HCO3-
NaHCO3 (sodium bicarbonate)
Generation of HCO3-
Absorption of H+ by other buffer systems
Secretion of H+
Kidneys

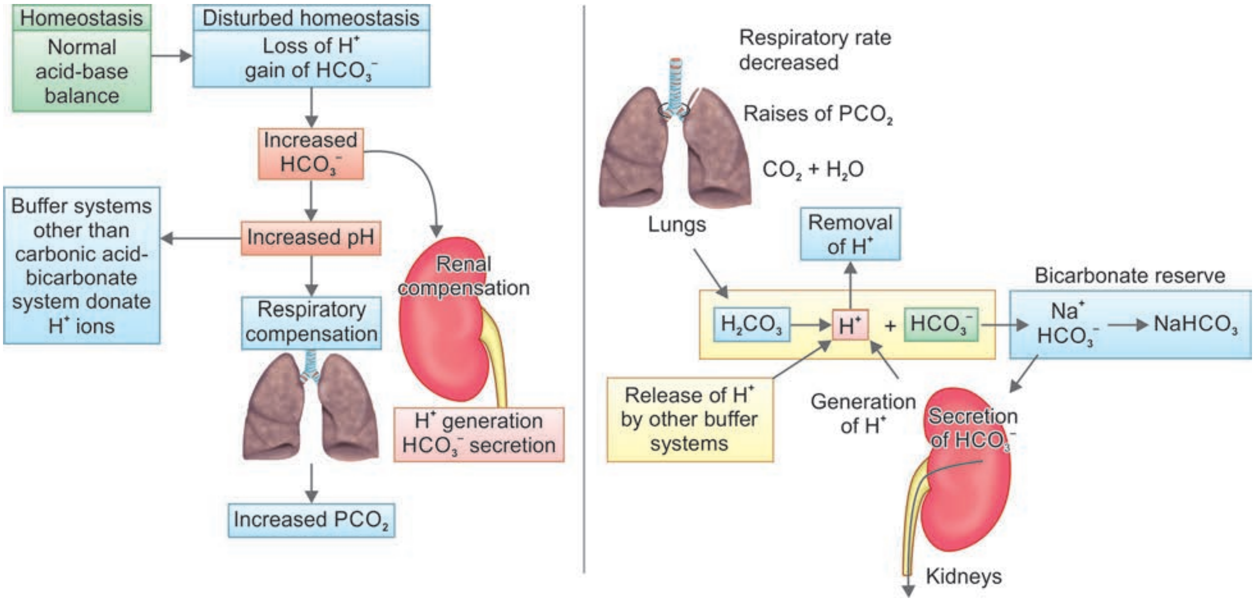
FIG. 11.13: Mechanism and response to acidosis.

Metabolic Alkalosis

Q. IM22.10 Enumerate the causes of describe the clinical and laboratory features of metabolic alkalosis.

Metabolic alkalosis is characterized by rise in both plasma bicarbonate level and plasma pH. The primary event is elevation of pH due to raised plasma bicarbonate concentration (HCO_3^-) or decreased acid **(Fig. 11.14).**

Types: Metabolic alkalosis may be hypovolemic or normovolemic. Causes of metabolic alkalosis are listed in **Table 11.28**.



Homeostasis
Normal acid-base balance
Disturbed homeostasis
Loss of H+ gain of HCO3-
Increased HCO3-
Increased pH
Buffer systems other than carbonic acid-bicarbonate system donate H+ ions
Respiratory compensation
Renal compensation
H+ generation HCO3- secretion
Increased PCO2
Respiratory rate decreased
Raises of PCO2
CO2 + H2O

Kidneys

FIG. 11.14: Mechanism and response to alkalosis.

TABLE 11.28: Causes of metabolic alkalosis.

- *Exogenous HCO_3^- loads*:
  - Acute alkali administration
  - Milk-alkali syndrome
- *Gastrointestinal origin*:
  - Vomiting
  - Gastric aspiration
  - Congenital chloridorrhea
  - Villous adenoma
- *Renal origin*:
  - Diuretics
  - Posthypercapnic state
  - Hypercalcemia/hypoparathyroidism
  - Recovery from lactic acidosis or ketoacidosis
  - Nonreabsorbable anions including penicillin, carbenicillin
  - Mg^{2+} deficiency
  - K^+ depletion

Chloride-responsive alkalosis:

- **Low urinary chloride concentration** (<15 mEq/L)
  - Gastric acid loss
  - Diuretic therapy
  - Volume depletion
  - Renal compensation for hypercapnea

Chloride-resistant alkalosis:

- **Elevated urinary chloride** (>25 mEq/L):
  - Primary mineralocorticoid excess
  - Severe potassium depletion
- **Associated with volume expansion**

Clinical Features (Table 11.29)

TABLE 11.29: Clinical features of metabolic alkalosis.

- Decreased myocardial contractility
- Arrhythmias
- Decreased cerebral blood flow
- Confusion
- Mental obtundation
- Neuromuscular excitability
- Hypoventilation
- Pulmonary microatelectasis

Management

- Correct the underlying cause to stop loss of acid
- *Metabolic alkalosis with hypovolemia*: Corrected by intravenous infusions of 0.9% saline with potassium supplements. This reverses the secondary hyperaldosteronism and the kidneys excrete the excess alkali in the urine.
- *Metabolic alkalosis with normal or increased volume*: Treatment of the underlying endocrine cause.
- *Acetazolamide may be considered for patients with posthypercapnic metabolic alkalosis*
- *Dialysis may be required if severe alkalosis or renal failure is present.*

Respiratory Acidosis

Q. IM22.11 Enumerate the causes and describe the clinical and laboratory features of respiratory acidosis.

Respiratory acidosis is a primary acid-base disorder characterized by ↑ PCO_2 and ↓ pH.

- Acute (<24 hours)
- Chronic (>24 hours)

Causes of Respiratory Acidosis (Table 11.30)

TABLE 11.30: Causes of respiratory acidosis.

CNS depression:

- *Drugs:* Opiates, sedatives, and anesthetics
- Obesity hypoventilation syndrome
- Stroke

Neuromuscular disorders

- *Neurologic:* Multiple sclerosis, polio, GBS, tetanus, botulism, and high cord lesions
- *End plate:* Myasthenia gravis, OP poisoning, and aminoglycoside toxicity
- *Muscle:* Hypokalemia, hypophosphatemia, muscular dystrophy

Airway obstruction

- COPD, acute aspiration, and laryngospasm

Chest wall restriction:

- *Pleural*: Effusions, empyema, pneumothorax, and fibrothorax
- *Chest wall*: Kyphoscoliosis, scleroderma, ankylosing spondylitis, and obesity

Severe pulmonary restrictive disorders:

- Pulmonary fibrosis
- *Parenchymal infiltration*: Pneumonia and pulmonary edema

Abnormal blood CO_2 transport

- *Decreased perfusion*: Heart failure, cardiac arrest, and pulmonary embolism
- Severe anemia
- Acetazolamide carbonic anhydrase inhibition
- *Red cell anion exchange:* Loop diuretics, salicylates, NSAID

Clinical Features (Box 11.11)

Box 11.11: Clinical features of respiratory acidosis.

- **RS (respiratory system):**
  - Stimulation of ventilation (tachypnea)
  - Dyspnea
- **CNS (central nervous system):**
  - ↑ cerebral blood flow • ↑ ICT, papilledema
  - CO_2 narcosis (disorientation, confusion, headache, lethargy)
  - Coma (arterial hypoxemia, ↑ ICT, anesthetic effect of ↑ PCO_2 >100 mm Hg)
- **CVS:** Tachycardia, bounding pulse
- **Others:** Peripheral vasodilatation (warm, flushed, sweaty)

Treatment

- The underlying causes should be corrected.
- Consider ventilatory support:
  - Noninvasive positive pressure ventilation
  - Intubation and mechanical ventilation
  - Rapid infusion of alkali is justified only in prolonged cardiopulmonary arrest.
  - Avoid overfeeding as changes in metabolism may worsen acidosis by increasing the rate of elimination of carbon dioxide.

Respiratory Alkalosis

Q. IM22.12 **Enumerate the causes and describe the clinical and laboratory features of respiratory alkalosis.**

- Most common acid-base abnormality in critically ill is characterized by ↓PCO_2 → ↑pH.
- Primary process: **Hyperventilation:**
  - **Acute:** $PaCO_2$ ↓, pH-alkalemic
  - **Chronic:** $PaCO_2$ ↓, pH normal/near normal

Causes of Respiratory Alkalosis (Table 11.31)

TABLE 11.31: Causes of respiratory alkalosis.

A. *Central nervous system stimulation*:
   1. Pain
   2. Anxiety, psychosis
   3. Fever
   4. Cerebrovascular accident
   5. Meningitis, encephalitis
   6. Tumor
   7. Trauma

B. *Hypoxemia or tissue hypoxia*:
   1. High altitude
   2. Septicemia
   3. Hypotension
   4. Severe anemia

C. *Drugs or hormones*:
   1. Pregnancy, progesterone
   2. Salicylates
   3. Cardiac failure

D. *Stimulation of chest receptors*:
   1. Hemothorax
   2. Flail chest
   3. Cardiac failure
   4. Pulmonary embolism

E. *Miscellaneous*:
   1. Hepatic failure
   2. Mechanical ventilation
   3. Heat exposure
   4. Recovery from metabolic acidosis

Clinical Features of Respiratory Alkalosis (Table 11.32)

TABLE 11.32: Clinical features of respiratory alkalosis.

- **CNS:**
  - ↑ Neuromuscular irritability (tingling, circumoral numbness)
  - **Tetany**
  - ↑ ICT (intracranial tension)
  - Light-headedness, confusion
- **CVS:**
  - CO and SBP ↑ (↑ SVR, HR)
  - Arrhythmias
  - ↓ myocardial contractility
- **Others**
  - Hypokalemia, hypophosphatemia
  - ↓ Free serum calcium—tetany
  - Hyponatremia, hypochloremia

Treatment

- Elimination of the underlying disorder
- In acute hyperventilation syndrome, sedation and **rebreathing into a bag** may terminate the attack.

GENETIC SYNDROMES WITH ACID-BASE AND POTASSIUM ABNORMALITIES (TABLE 11.33 AND FIG. 11.15)

TABLE 11.33: Genetic syndromes with acid-base and potassium abnormalities.

Syndrome	*Genetics*	*Blood pressure*	*Acid-base disorder and potassium*	*Renin and aldosterone*	*Other features*	*Treatment*
Liddle syndrome	ENaC gene Chr 16p12 Autosomal dominant	Hypertension	Metabolic alkalosis Hypokalemia	Both suppressed	Salt-sensitive	ENaC inhibitors
Glucocorticoid-remediable aldosteronism (GRA)	CYP11B1/CYP11B2 Chr 8q24 Autosomal dominant	Hypertension	Metabolic alkalosis Hypokalemia	Renin suppressed Aldosterone normal or elevated	Unusual urine steroid metabolites	Corticosteroid therapy
Apparent mineralocorticoid excess (AME)	11β-HSD 2 Chr 16q22 Autosomal recessive	Hypertension	Metabolic alkalosis Hypokalemia	Both suppressed	Nephrocalcinosis can be seen Elevated urine cortisol:cortisone ratio	Spironolactone and ENaC inhibitors
Mineralocorticoid receptor activating mutation (Geller syndrome)	NR3C2 Chr 4q31 Autosomal dominant	Hypertension	Metabolic alkalosis Hypokalemia	Both suppressed	Exacerbated in pregnancy Spironolactone acts as agonist	ENaC inhibitors

FIG 11.15: Sites of the nephron affected with genetic syndromes with acid-base potassium abnormalities.

CHAPTER 12

Diabetes Mellitus

INTRODUCTION

Q. IM11.1 Define and classify diabetes.

Definition

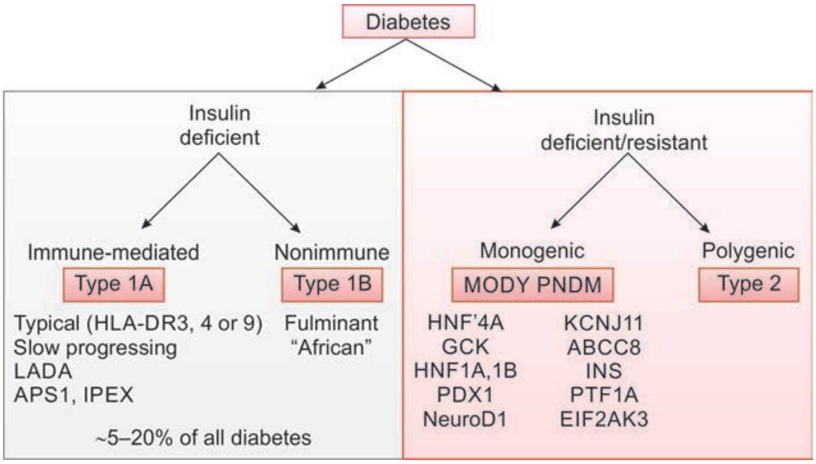
Diabetes mellitus (DM) is a metabolic cum vascular syndrome of multiple etiologies characterized by chronic hyperglycemia with disturbances of carbohydrate, fat, and protein metabolism resulting from defects in insulin secretion, insulin action, or both leading to changes in both small blood vessels (microangiopathy) and large blood vessels (macroangiopathy).

The International Diabetes Federation (IDF) estimated that in 2015, 415 million people worldwide were diagnosed with DM. This number is expected to go up to 642 million by 2040.

China and India have the largest number of diabetics (109.6 million and 69.2 million, respectively) with the prevalence in Southeast Asia second only to the Western Pacific. β-cell dysfunction may play a more prominent role in the pathogenesis of type 2 diabetes in population or subgroups where low body mass index (BMI) coexists with a high prevalence of the disease, as seen in Southeast Asia, the type 2B, or the Asian-Indian phenotype.

CLASSIFICATION AND ETIOLOGY

Diabetes mellitus is classified according to etiopathogenesis that leads to hyperglycemia into different groups (**Fig. 12.1 and Table 12.1**), but **majority of cases fall into one of two** broad classes namely: **Type 1** (not type I) and **Type 2** (not type II).



Diabetes
Insulin deficient
Immune-mediated
Type 1A
Typical (HLA-DR3, 4 or 9)
Slow progressing
LADA
APS1, IPEX
Nonimmune
Type 1B
Fulminant
"African"
~5–20% of all diabetes
Insulin deficient/resistant
Monogenic
MODY PNDM
HNF'4A
GCK
HNF1A,1B
PDX1
NeuroD1
KCNJ11
ABCC8
INS
PTF1A
EIF2AK3
Polygenic
Type 2

FIG. 12.1: Types of diabetes mellitus.

(ABCC8: ATP-binding cassette transporter subfamily C member 8; APS1: Autoimmune polyendocrine syndrome type 1; EIF2AK3: Eukaryotic translation initiation factor 2-alpha kinase 3; GCK: Glucokinase; HNF4: Hepatocyte nuclear factor 4; HLA: Human leukocyte antigen; IPEX: Immune dysregulation, polyendocrinopathy, enteropathy, X-linked; INS: Insulin; KCNJ11: Potassium inwardly rectifying channel subfamily J member 11; LADA: Latent autoimmune diabetes in adults; MODY: Maturity-onset diabetes of the young; NeuroD1: Neurogenic differentiation 1; PDX1: Pancreatic and duodenal homeobox 1; PNDM: Permanent neonatal diabetes mellitus; PTF1A: Pancreas transcription factor 1 subunit alpha)

TABLE 12.1: Classification of diabetes mellitus.

- **Type 1 diabetes** (destruction of β-cell usually leading to absolute deficiency of insulin):
  - Type 1A: Immune-mediated
  - Type 1B: Idiopathic
- **Type 2 diabetes** (may range from predominantly insulin resistance with relative insulin deficiency to a predominantly insulin secretory defect with insulin resistance)
- **Other specific types of diabetes:**
  - **Genetic defects of β-cell development or function characterized by mutations in:**
    - Hepatocyte nuclear factor 4α (HNF4α) and maturity-onset diabetes of the young 1 (MODY 1)
    - Glucokinase (MODY 2)
    - HNF1α (MODY 3)
    - Insulin promoter factor 1 (MODY 4)
    - Hepatocyte nuclear factor 1β (MODY 5)
    - Neurogenic differentiation factor 1 (MODY 6)
  - **Genetic defects in insulin action:** Type A insulin resistance, Leprechaunism, Rabson–Mendenhall syndrome, and lipodystrophy syndromes
  - **Exocrine pancreatic defects:** Pancreatitis, pancreatectomy, hemochromatosis, pancreatic neoplasm, cystic fibrosis, and fibrocalculous pancreatopathy
  - **Endocrinopathies:** Acromegaly, Cushing syndrome, hyperthyroidism, pheochromocytoma, and glucagonoma
  - **Infections:** Cytomegalovirus, Coxsackie B virus, and congenital rubella (hepatitis C virus infection has been associated with an increased incidence of diabetes, but it is uncertain if there is a direct relationship)
  - **Drugs or chemical-induced:** Glucocorticoids, pentamidine, nicotinic acid, thyroid hormone, diazoxide, β-adrenergic agonists, thiazides, phenytoin, α-interferon, asparaginase, and tacrolimus
  - **Genetic** syndromes **sometimes associated with diabetes:** Down syndrome, Klinefelter syndrome, Turner syndrome, Wolfram syndrome, DIDMOAD (diabetes insipidus, diabetes mellitus, optic atrophy, and deafness), Friedreich's ataxia, Huntington's disease, Laurence–Moon–Biedl syndrome, myotonic dystrophy, porphyria, and Prader–Willi syndrome
  - **Uncommon forms of immune-mediated diabetes:** "Stiff-man" syndrome and anti-insulin receptor antibodies
- **Gestational diabetes mellitus (GDM)**
- **Latent autoimmune diabetes in adults (LADA)**

- **Type 1 DM:** In this, there is **absolute (complete or near-total) deficiency of insulin**. It is subdivided into two subtypes namely **type 1A**, which is due to **autoimmune** destruction of β-cells and **type 1B**, where the cause of β-cell destruction is **unknown**.
- **Type 2 DM:** It constitutes a **heterogeneous group** characterized by variable degrees of **insulin resistance, impaired insulin secretion, and increased glucose production**. It also develops due to several genetic and metabolic syndromes.
  - **Risk categories:** Type 2 diabetes mellitus is usually preceded by a period of abnormal glucose homeostasis classified as **impaired fasting glucose (IFG) or impaired glucose tolerance (IGT)**.

Features of Current Classification of Diabetes Mellitus

- The terms insulin-dependent diabetes mellitus (IDDM) and noninsulin-dependent diabetes mellitus (NIDDM) are no longer used now because many patients with T2DM eventually need insulin for control of hyperglycemia.
- The age or treatment modality is not a criterion for classification. Type 1 DM most often occurs in younger patients before the age of 30 years and an autoimmune destruction of P-cell can start at any age. However, about 10% of patients above the age of 30 years have type 1 DM. T2DM usually develops with increasing age. However, it is now being diagnosed more frequently in children and young adults (particularly in obese adolescents).

Metabolic Effects of Lack of Insulin (Table 12.2)

TABLE 12.2: Functions of insulin and metabolic effects of insulin deficiency.

Functions of insulin	*Consequences of insulin deficiency*
Functions that decreases blood glucose level	**Insulin deficiency increases the blood glucose level**
Increases activity of glycolytic enzymes	Decreased activity of glycolytic enzymes
Increases glycogen synthesis	Glycogen breakdown into glucose increases (gluconeogenesis)
Increases uptake of glucose by skeletal and cardiac muscle	Decreased glucose transport into skeletal and cardiac muscle
Decreases activity of gluconeogenic enzymes	Increased activity of gluconeogenic enzymes (gluconeogenesis)
Lipid metabolism: Increases lipid synthesis	Lipolysis (raised plasma free fatty acids) and ketogenesis
Protein metabolism: Enhances tissue uptake of amino acids and accelerates protein synthesis	Decrease in tissue uptake of amino acids and reduced protein synthesis
Other functions	
Increases transmembrane K^+ transport	Decrease in movement of K^+ into the cell
Decreases cyclic adenosine monophosphate (AMP) level in adipose tissue and liver	Increased cyclic AMP levels in adipose tissue and liver

ETIOPATHOGENESIS OF TYPE 1 DIABETES MELLITUS

Q. IM11.2 **Describe and discuss the epidemiology and pathogenesis and risk factors and clinical evolution of type 1 diabetes.**

Q. IM11.4 **Describe and discuss the genetic background and the influence of the environment on diabetes.**

It accounts for ~**5–10%** of all cases.

Age: Most common in **childhood (younger than 20 years** of age). Since, it can develop at any age; the term "juvenile diabetes" should be avoided.

Etiology

- **Autoimmune disease** is characterized by:
  - **Pancreatic β-cell destruction**
  - **Absolute deficiency of insulin**
- **Idiopathic:** It is a rare form in which there is no evidence for autoimmunity.

Pathogenesis of Type 1 Diabetes Mellitus (Fig. 12.2)

- It is an **autoimmune disease** that involves interplay of both genetic susceptibility and environmental factors.
  Genetic susceptibility: Incidence of type 1 diabetes is greater in twins of affected individuals than in the general population and greater in monozygotic than in dizygotic twins.
- **Human leukocyte antigen (HLA) genes:** About 95% of patients with type 1 diabetes have either **HLA-DR3 or HLA-DR4, or both**, compared with the general population.
  Environmental factors: **Viral infections may trigger islet cell destruction** and associations have been found between type 1 diabetes and infection with ***mumps, rubella, Coxsackie B, or cytomegalovirus***. Environmental event initiates the process in genetically susceptible individuals. Relative deficiency of vitamin D may also be responsible.
  Mechanisms of β-cell destruction (Fig. 12.2): The autoimmune damage starts many years before the disease becomes clinically evident. An inflammatory response in the pancreas called "**insulitis**" develops and there is infiltration of the islets with activated T lymphocytes.
- **Phases in the development of diabetes mellitus:**
  - **Phase with normal glucose tolerance:** In most of the patients, islet cell autoantibodies appear much earlier than overt diabetes. β-cell mass and insulin secretion progressively decrease; however, normal levels of blood glucose are maintained.

Absolute deficiency of insulin

FIG. 12.2: Pathogenesis of type 1 diabetes mellitus.
(CTLs: Cytotoxic T lymphocytes; HLA: Human leukocyte antigen; IFN-γ: Interferon-γ; TNF: Tumor necrosis factor)

TABLE 12.3: Various autoimmune disorders that can be associated with type 1 diabetes mellitus (DM).

Autoimmune diseases	***Autoantibody types***	***Autoantibody (%)***	***Disease prevalence (%)***
Addison's disease	21-hydroxylase	1.5	0.5
Celiac disease	Transglutaminase	12	6
Pernicious anemia	Parietal cell	21	2.6
Thyroiditis or Graves' disease	Peroxidase or thyroglobulin	25	4

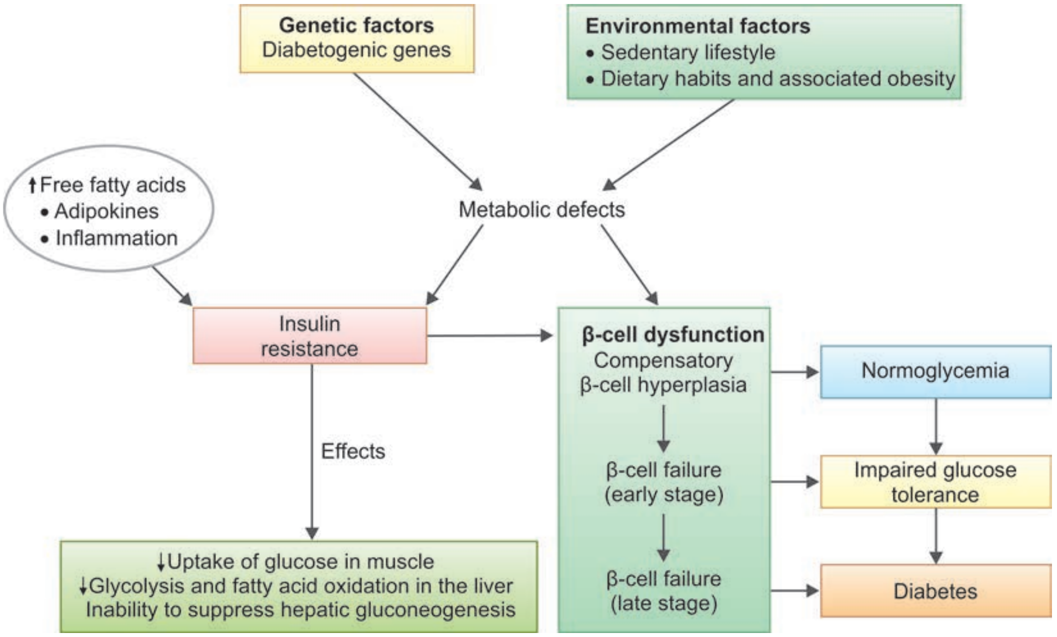
  - **Phase of impaired glucose intolerance:** Features of diabetes do not become evident even with destruction of 70–80% of β-cells. At this point, residual functional β-cells cannot maintain glucose tolerance and patient develops glucose intolerance.
  - **Phase of frank diabetes:** Stress, infection, or puberty may be associated with increased insulin requirements and may trigger the *transition* from glucose intolerance to frank diabetes.
  - ***Honeymoon phase:*** *After the initial clinical presentation of frank type 1 DM, a phase may occur during which time patient is euglycemic with modest doses of insulin or rarely without insulin for some time. This is referred to as honeymoon phase. This usually lasts for a few months after which the patient develops frank DM again.*
    - **Hyperglycemia and ketosis** occur after >**90% of the β-cells have been destroyed** by an autoimmune process.
    - **Immunologic markers:** These include autoantibodies against islet cell, insulin, glutamic acid decarboxylase (GAD65), zinc transporter 8 (ZnT8), and tyrosine phosphatase such as insulinoma-associated protein-2 (IA-2) and IA-2p. One or more of these autoantibodies are detected in 85–90% of individuals when fasting hyperglycemia is initially detected.
- Type 1 DM can be associated with various autoimmune disorders as outlined in **Table 12.3**.
- **Slow-burning variant of type 1 DM:** It is characterized by slower progression to insulin deficiency and develops in later life and is sometimes called **latent autoimmune diabetes in adults (LADA)**. LADA may be difficult to distinguish from T2DM.

PATHOGENESIS OF TYPE 2 DIABETES MELLITUS (FIG. 12.3)

Q. IM11.3 Describe and discuss the epidemiology, pathogenesis, risk factors, and clinical evolution of type 2 diabetes.

Type 2 diabetes is a **multifactorial disease**. The four major factors are: (1) **increasing age**, (2) **obesity**, (3) **ethnicity**, and (4) **family history**.

Type 2 diabetes is associated with central obesity, hypertension, hypertriglyceridemia, and decreased high-density lipoprotein (HDL) cholesterol (metabolic syndrome).



Genetic factors
Diabetogenic genes
Environmental factors
• Sedentary lifestyle
• Dietary habits and associated obesity
↑Free fatty acids
• Adipokines
• Inflammation
Metabolic defects
Insulin resistance
β-cell dysfunction
Compensatory β-cell hyperplasia
Normoglycemia
Effects
β-cell failure (early stage)
Impaired glucose tolerance
β-cell failure (late stage)
Diabetes
↓Uptake of glucose in muscle
↓Glycolysis and fatty acid oxidation in the liver
Inability to suppress hepatic gluconeogenesis

FIG. 12.3: Pathogenesis of type 2 diabetes. Insulin resistance associated with obesity is induced by free fatty acids, adipokines, and chronic inflammation in adipose tissue. Insulin resistance causes β-cells of pancreas to undergo compensatory hyperplasia and the resulting hypersecretion of insulin maintains normoglycemia. However, at some point, β-cell compensation is followed by β-cell failure and diabetes develops.

- Environmental factors play a role and include:
    - **Sedentary lifestyle**
    - **Dietary habits and associated obesity:** Overeating, obesity, and underactivity are associated with the development of T2DM.
- **Genetic factors:** It is much more significant in T2DM than in type 1 DM **(Fig. 12.4)**.
    - Type 2 diabetes has a **concordance rate of 35–60% in monozygotic twins compared with 17–30% in dizygotic twins.**
    - Lifetime risk for type 2 diabetes in an offspring is more than double, if **both parents** are **affected**.
    - Diabetogenic genes have been found.
- In contrast to type 1 DM, in T2DM, there is no HLA relationship and there is no evidence of an autoimmune basis. Pancreatic β-cell mass is intact in T2DM, in contrast to type 1 DM. The β-cell mass is increased.

Genome Wide Association Studies (GWAS)

- The development of new genotyping technologies and the realization that we inherit stretches of the genome together as haplotypes facilitated the cataloging of common variants (HAPMAP, 1000 genomes) and allowed for new possibilities to apply unbiased global approaches to screen millions of common variants for association with complex diseases.
- Advances in genomic technology have initiated a myriad of novel genetic discoveries including more than 2,000 common variants contributing to risk of complex disease.
- The first was a GWAS on early-onset T2D reporting two new diabetes loci: *HHEX* and *SLC30A8*.
- Variants in UBE2E2, C2CD4A-C2CD4B, ANK1, GRK5, RASGRP1, PAX4 and others were discovered in the East Asian population and replicated in Caucasians with variants in PPARγ, KCNJ11, TCF2, TCF7L2, CDKAL1, CDKN2A-CDKN2B, IDE-KIF11-HHEX, IGF2BP2, whereas variants in MTNR1B, SLC30A8, KCNQ1, CDC123, GLIS3, HNF1B, DUSP9 and others were identified in Caucasian populations and were also replicated in East Asian population.
- Variants in *GLIS3, PEPD, ITM2-R3HDML-HNF4A, KCNK16, MAEA, GCC1-PAX4, PSMD6*, and *ZFAND* were discovered in populations of East Asian descent, *SLC16A11* in the Mexican population, and *TMEM163* in chr 2 in a North Indian population.

Characteristics of Type 2 Diabetes Mellitus

These include: (1) insulin resistance, (2) abnormal/impaired insulin secretion/action, (3) increased hepatic production of glucose, and (4) abnormal fat metabolism.

Genome-wide association studies (GWASs) have linked aberrations in >40 different genes with an increased risk of T2DM. These genes are involved in the regulation of various biological processes including cellular development, differentiation, and physiological functions.

Epigenetics and deoxyribonucleic acid (DNA) methylation play an important role in the pathogenesis of T2DM including insulin production, β-cell secretion, and resistance. This regulation can either occur by affecting the DNA methylation of the

insulin gene itself or by affecting the DNA methylation status of other genes that regulate insulin production, secretion, and sensing.

INSULIN RESISTANCE

Q. Write short essay/note on insulin resistance.

- Insulin resistance is **the decrease/failure of target (peripheral) tissues to insulin action**.
- Main factors in the development of insulin resistance are combination of genetic susceptibility and **obesity**. The obesity accompanying T2DM is central obesity and central adipose tissue is more "lipolytic" than peripheral sites. Insulin resistance is induced by free fatty acids (FFAs), adipokines, and chronic inflammation in adipose tissue.
- **Consequences of insulin resistance:**
  - **Decreased uptake of glucose in muscle** results in postprandial hyperglycemia. The defects in the uptake are due to defect in the receptors present in target tissues and usually at the postreceptor level.
  - **Reduced glycolysis** and **fatty acid oxidation** in the liver.
  - **Inability to suppress hepatic gluconeogenesis.**
- **Abnormalities of insulin secretion and action:**
- **β-cell dysfunction:** Abnormalities (abnormal/impaired) of insulin secretion develops early in the course of type 2 diabetes and is due to β-cell dysfunction. β-cell dysfunction is multifactorial in origin. In type 2 diabetes, β-cell dysfunction manifests as **inadequate insulin secretion by the pancreatic β-cells (relative insulin deficiency)** in association with insulin resistance and hyperglycemia.
- **Compensatory β-cell hyperplasia:** Pancreatic β-cells **initially respond** to long-term demands of peripheral insulin resistance **by undergoing compensatory hyperplasia leading to increased insulin secretion (hypersecretion)**. Thus, the hyperinsulinemic state can compensate for peripheral resistance and maintain normal blood glucose for years.
  - **β-cell failure (early stage):** However, at some point, β-cells exhaust their capacity to adapt. β-cell compensation cannot maintain normal blood sugar level. In this stage, the patient develops IGT.
  - **β-cell failure (late stage):** The early stage of cell failure is followed by decreased insulin secretion, hyperglycemia, and frank diabetes develops.
- **Increased hepatic production of glucose:** Relative lack of insulin is associated with increased production of glucose from the liver (due to inadequate suppression of gluconeogenesis) and reduced glucose uptake by peripheral tissues. Increased hepatic glucose output produces fasting hyperglycemia.
- **Abnormal fat metabolism:** Insulin resistance in adipose tissue causes lipolysis and increased production of free fatty acid from adipocytes. This leads to increased synthesis of lipid [very-low-density lipoprotein (VLDL) and triglyceride] in hepatocytes. Deposition of fat in the liver is a common association with central obesity and is increased by insulin resistance and/or deficiency. The deposition of fat/lipid or steatosis in the liver may result in nonalcoholic fatty liver disease (NAFLD). This is also responsible for the dyslipidemia observed in T2DM (i.e., **raised triglycerides, decreased HDL, and raised small dense LDL).**

  Hyperglycemia (**glucotoxicity**) and elevated free fatty acid levels (**"lipotoxicity"**) and dietary fat may also cause further β-cell loss and deterioration of glucose homeostasis.
- **Phases of insulin resistance:**
  - **Phase 1:** Normal plasma glucose due to compensatory increase in insulin secretion.
  - **Phase 2:** Worsening of insulin resistance leading to postprandial hyperglycemia despite elevated insulin secretion.
  - **Phase 3:** Insulin resistance remains constant and decline in β-cell function produces fasting hyperglycemia.

Clinical findings in insulin resistance: Acanthosis nigricans and skin tags.

Pathophysiology of T2DM

The **ominous octet** of presented in **Figure 12.5**.

CLINICAL FEATURES OF DIABETES MELLITUS

Q. Write short essay/note on clinical features of diabetes mellitus/type 1 diabetes mellitus/type 2 diabetes mellitus.

Usually, the clinical features of type 1 and T2DM are distinctive.

Type 1 Diabetes Mellitus

- **Age:** Usually begins before the age of 30 years, but can occur at any age.
- Weight is normal to lean (wasted).

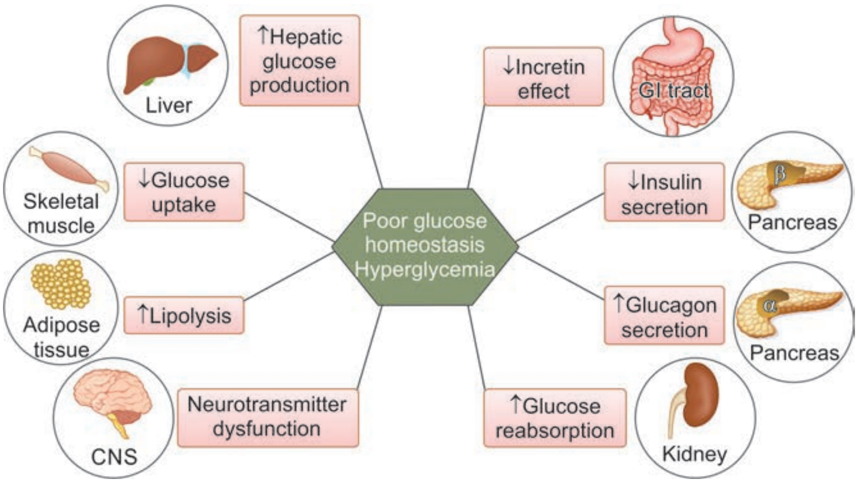

FIG. 12.5: Pathophysiology of type 2 diabetes mellitus—the ominous octet. Multiple drugs in combination may be needed to improve glucose homeostasis. The treatment should target the underlying pathophysiology.
(CNS: central nervous system)

- **Classical triad of diabetes:** The onset of symptoms may be abrupt with **polyuria, polydipsia, and polyphagia** to metabolic derangements. Weight loss may develop over days or weeks.
- Diabetic ketoacidosis (DKA) may be the initial presentation in approximately 25% of adults with newly diagnosed type 1 diabetes.
- **Insulin requirement:** In the initial 1 or 2 years, the exogenous insulin required may be minimal because of endogenous insulin secretion. But later, its requirement suddenly increases.
- Characteristically, the **plasma insulin is low** and **C-peptide levels** are low and unmeasurable. *Glucagon levels are raised and suppressible with insulin.*

Type 2 Diabetes Mellitus

- **Age:** Usually begins in older **above the age of 40 years** and frequently in **obese individuals**. Due to increase in obesity and sedentary lifestyle, it is now detected also in children and adolescents.
- **Presentation:** The symptoms develop gradually over a period of months to years. Examples are **polyuria, polydipsia, nocturia, blurred vision, unexplained weakness, or weight loss**.
- Polyuria occurs when the serum glucose concentration rises significantly above 180 mg/dL, exceeding the renal threshold for glucose reabsorption, which leads to increased urinary glucose excretion.
- Glycosuria causes osmotic diuresis (i.e., polyuria) and hypovolemia, which, in turn, can lead to polydipsia.
- In **asymptomatic individuals**, the **diagnosis is made after routine blood** (hyperglycemia) or **urine testing (glycosuria)**.
- Patients may complain of symptoms such as lack of energy, blurring of vision (due to glucose-induced changes in refraction), or pruritus vulvae or balanitis caused by *Candida* infection.
- Many patients may present with one of the chronic complications of diabetes and are found to be diabetic on investigations. These include staphylococcal skin infections, retinopathy, polyneuropathy, erectile dysfunction, and arterial disease (myocardial infarction or peripheral gangrene).
- Adults with type 2 diabetes can present with a hyperosmolar hyperglycemic state (HHS) characterized by marked hyperglycemia, severe dehydration, and obtundation, but without ketoacidosis. DKA as the presenting symptom of type 2 diabetes is also uncommon in adults.
- **Insulin levels in the plasma are normal to high**. Glucagon levels are raised, but resistant to insulin.

LATENT AUTOIMMUNE DIABETES IN ADULTS

Q. Write short note on LADA.

- Latent autoimmune diabetes in adults is a form of **autoimmune type 1 diabetes**, which is diagnosed in individuals who are older than the usual age of onset of type 1 diabetes. Often, LADA is mistaken for **type 2 diabetes** based on their age at the time of diagnosis.
- Alternate terms for "LADA" include late-onset autoimmune diabetes of adulthood, "slow-onset type 1" diabetes, and "type 1.5 diabetes".

Features of Latent Autoimmune Diabetes in Adults

- **Age:** Usually >30–35 years of age.
- Clinical presentation: Similar to nonobese type 2 diabetes.
- Initial control achieved with diet alone or diet plus oral antidiabetic drugs (OADs). Insulin dependency occurs within months (rarely can take years). LADA shares an increased frequency of risk for an HLA-DQB1 genotype than patients with type 1 diabetes and for a variant in the transcription factor 7-like 2 (*TCF7L2*) gene with patients with type 2 diabetes.
- Other features of type 1 DM:
  - Low fasting and postglucagon-stimulated C-peptide levels
  - Islet cell antibody (ICA) and GAD65 positive.
- Importance of diagnosis: High risk of progression to insulin dependency.
  - Avoid metformin treatment
  - Early introduction of insulin therapy.

MATURITY-ONSET DIABETES OF THE YOUNG

Q. Write short essay on maturity-onset diabetes of the young (MODY).

Maturity-onset diabetes of the young (MODY) is a heterogeneous disorder characterized by noninsulin-dependent monogenic form of diabetes diagnosed at a young age (<25 years) with autosomal dominant transmission and lack of autoantibodies accounting for 2–5% of diabetes.

- **Mutations** in several **transcription factors** or in **glucokinase** result in insufficient insulin release from pancreatic β-cells causing MODY. Almost 11 subtypes of MODY are identified based on the mutated gene.
- MODY can **occur at any age**. About 70% forms of MODY are MODY 3 (hepatic transcription factor 1 gene) and 10% MODY 2 (glucokinase gene).

Features of Maturity-onset Diabetes of the Young (FIG. 12.6)

- **Age:** Young onset of diabetes <25 years of age
- Strong family history of early-onset diabetes (2–3 generations affected)
- Evidence of macrovascular complications in earlier generation

(BMI: Body mass index; GCK: Glucokinase; HbA1c: Glycated hemoglobin; HNF1A: Hepatocyte nuclear factor 1 alpha; MODY: Maturity-onset diabetes of the young)

- Sulfonylurea sensitivity and noninsulin dependence (not requiring insulin even after 5 years of diagnosis)
- Absence of insulin resistance phenotype: Normal blood pressure, triglycerides, and HDL.

Subtypes of Maturity-onset Diabetes of the Young (Table 12.4)

Differences between type 1 DM, type 2 DM, and MODY are listed in **Table 12.5**.

Q. Write short note on fibrocalculous pancreatic diabetes (FCPD).

Fibrocalculous Pancreatic Diabetes

- Pancreatogenic diabetes is classified by the American Diabetes Association (ADA) and by the World Health Organization as **type 3c diabetes mellitus (T3cDM)**.
- Prevalence of 5–10% among all patients with DM.
- Seen almost exclusively in developing countries, FCPD is characterized by a triad of abdominal pain, steatorrhea, and diabetes.
- Genes implicated are serine protease inhibitor Kazal type 1 (*SPINK1*), *cathepsin B*, and cystic fibrosis transmembrane conductance regulator (*CFTR*).
- 70% are males in their second and third decades.
- Classically, patients are malnourished with low BMI, but very high insulin requirements. While the presence of microvascular complications are similar as in other types of diabetes, the presence of macrovascular complications are rare, believed to be due to young age, lean body, and low lipid levels.
- Risk of pancreatic cancer is very high in this population.

Other Types of DM

- **Maternally inherited diabetes and deafness (MIDD)** is due to the A3242G mutation in mitochondrial DNA (mtDNA). As mtDNA is only transmitted from the mother, MIDD shows maternal transmission. In addition to hearing loss, many patients also display neurological problems similar to patients with the MELAS syndrome (mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke), which is also caused by the same mutation in mtDNA.
- **Neonatal diabetes** is defined as diabetes with onset at birth or during the first 6 months of life with both transient and permanent forms. Mutations in several genes have been shown to cause neonatal diabetes (*KCJN11, SUR1, GCK, INS*, etc.),

TABLE 12.4: Types of maturity-onset diabetes of the young (MODY).

MODY types	*Defective chromosomes*	*Mutation in*	*Phenotypic features*
1.	20q	Hepatocyte nuclear factor 4α (HNF4α)	Adolescent/early adult: Progressive in insulin secretory defect
2.	7p	Glucokinase (GCK) gene	Since birth: Stable mild fasting hyperglycemia
3.	12q	HNF1α	Adolescent/early adult: Progressive insulin secretory defect
4.	13q	Insulin promoter factor-1 (IPF-1)	Early adult: Very rare, mild diabetes
5.	17q	HNF1β	Adolescent: Progressive diabetes
6.	2q	NeuroD1	Early adult: Rare
7.	2p	KLF11	Early adult: Pancreatic atrophy
8.	9q	Carboxyl ester lipase (CEL)	Early adult: Rare
9.	7q	PAX4	Early adult: Rare
10.	11p	INS	Rare
11.	8p	BLK	Rare

(BLK: B lymphocyte kinase; NeuroD1: Neurogenic differentiation 1; PAX4: Paired box gene 4; KLF11: Krüppel-like factor 11)

TABLE 12.5: Differences between type 1 DM, type 2 DM, and MODY.

Features	*Type 1 DM*	*Type 2 DM*	*MODY*
Frequency	Common	Increasing	2–5% of type 2 DM
Genetics	Polygenic	Polygenic	Monogenic autosomal dominant
Family history	<15%	>50%	100%
Ethnicity	Different races	Different races	Asians, Polynesians, and indigenous Australians
Age of onset	Throughout childhood	Postpuberty	<25 years
Severity of onset	Acute and severe	Mild	Mild/asymptomatic
Ketosis/diabetic ketoacidosis	Common	Uncommon	Rare
Obesity association	–	>90%	±
Acanthosis nigricans and metabolic syndrome	Absent	Common	Absent
Autoimmunity	Positive	Negative	Positive
Pathophysiology	β-cell destruction	Insulin resistance and relative insulinopenia	β-cell dysfunction

(DM: Diabetes mellitus; MODY: Maturity-onset diabetes of the young) and an appropriate genetic diagnosis is a prerequisite for optimal treatment. Patients with mutations in the *KCJN11* gene do not only have severe diabetes but also developmental defects (DEND). These conditions are improved after switching from insulin treatment to treatment with large doses of sulfonylureas.

DIAGNOSIS OF DIABETES MELLITUS

Q. Discuss the diagnostic criteria for diabetes mellitus.

- Classical symptoms: Diabetes may present with polyuria, polydipsia, and polyphagia. There may be significant weight loss, despite polyphagia.
- Symptoms due to depressed immune status: Diabetes is associated with immune dysfunction. It may result in activation of pulmonary tuberculosis, nonhealing of wounds, candidal pruritus vulvae or balanitis, recurrent styes, and recurrent urinary tract infections.
- End-organ involvement: Some patients may present with symptoms of end-organ involvement such as retinopathy, nephropathy, or neuropathy.
- Risk factors of DM: Some patients may have identifiable risk factors such as obesity, pregnancy, and first-degree relatives of known diabetics.

Normal Glucose Levels

- Normally, the **blood glucose levels** are maintained in a very narrow range of **70–120 mg/dL**.
- Glycemia can be classified into three categories: (1) euglycemia (normal), (2) prediabetes (impaired), and (3) diabetes **(Table 12.6)**.

Prediabetes: It is defined as condition in which there is **IGT**, but elevated **blood sugar does not reach the criterion accepted for an outright diagnosis of diabetes**. Prediabetes may be either IFG based upon a fasting plasma glucose (FPG) result or IGT based upon the fasting and 2-hour oral glucose tolerance test (OGTT) results. Recently, the term "prediabetes" has been changed to **"categories of increased risk for diabetes"**. The criteria for diagnosis are mentioned in **Table 12.6**.

TABLE 12.6: WHO criteria: Levels of blood glucose in normal, prediabetes, and diabetes in glucose tolerance test.

	Euglycemic	***Prediabetes (impaired glucose tolerance)***	***Diabetes***
Fasting glucose level	<100 mg/dL	>100 mg/dL but <126 mg/dL	>126 mg/dL on more than one occasion
2-hour OGTT (75 g anhydrous glucose in water)	<140 mg/dL	>140 mg/dL but <200 mg/dL	>200 mg/dL

(OGTT: Oral glucose tolerance test)

Q. Write short note/essay on impaired fasting glucose (IFG).

Impaired fasting glucose: **Fasting glucose** level is **>100 mg/dL but <126 mg/dL** (whole-blood glucose ≥88 mg/dL but <110 mg/dL). This diagnostic category does not need glucose tolerance test. It is not a distinct clinical entity, but individuals have the future risk of frank diabetes and cardiovascular disease.

Q. Write short note/essay on impaired glucose tolerance (IGT).

- **Impaired glucose tolerance: GTT** values **>140 mg/dL but <200 mg/dL** (whole-blood glucose between 125 and 175 mg/dL 2 hours after oral glucose load). IGT is not a disease, but a risk factor for future diabetes and cardiovascular disease. This is heterogeneous group of people who are obese, have fatty liver, and are on medication, which can alter glucose tolerance. IGT patients have the same risk of cardiovascular disease as those with frank diabetes, but microvascular complications are rare.
    - Additionally, glycated hemoglobin (HbA1c) in the range of **5.7–6.4%** is also included in "prediabetes". **Risks in prediabetes:** (1) **Progression to frank diabetes** over time and (2) **cardiovascular disease**.
    - Impaired fasting glucose and IGT are associated with the **metabolic syndrome**.
- **Medical nutrition therapy** aimed at reducing 5–10% loss of body weight and exercise has been found to prevent or delay the development of diabetes in individuals with IGT. However, no drug therapy is recommended at present. Acarbose and metformin have been tried in prediabetes.

Diagnostic Criteria for Diabetes Mellitus

Q. Write short essay/note on oral glucose tolerance test: WHO diagnostic criteria.

WHO Diagnostic Criteria for Diabetes Mellitus (Box 12.1)

Q. Write short note on World Health Organization (WHO) diagnostic criteria for diabetes mellitus.

Box 12.1: WHO criteria for the diagnosis of diabetes mellitus.

- Fasting plasma glucose >126 mg/dL (7.0 mmol/L)
- Random plasma glucose >200 mg/dL (11.1 mmol/L) with classical signs and symptoms
- One abnormal laboratory value is diagnostic in symptomatic individuals:
  - Two values are needed in asymptomatic individuals
  - The glucose tolerance test is only required for borderline cases and for diagnosis of gestational diabetes
- HbA1c >6.5 (48 mmol/mol).

(HbA1c: Glycated hemoglobin: WHO: World Health Organization)

Box 12.2: Criteria for diagnosis of diabetes (American Diabetes Association, 2016).

Typical symptoms of diabetes mellitus (DM) (polyuria, polydipsia, and weight loss) + random plasma glucose **≥200 mg/dL** (symptoms of diabetes + random whole-blood glucose >175 mg/dL)

Or

Fasting plasma glucose **≥126 mg/dL** (fasting whole-blood glucose ≥110 mg/dL)

Or

2-hour plasma glucose **≥200 mg/dL** during an oral glucose tolerance test (OGTT) (whole blood ≥175 mg/dL during an oral 75-g glucose tolerance test)

Or

Glycated hemoglobin (HbA1c) **≥6.5%**

Criteria for Diagnosis of Diabetes (American Diabetes Association) (Box 12.2)

Q. Write short note/essay on American Diabetes Association (ADA) criteria for the diagnosis of diabetes mellitus.

Q. Write short note/essay on differential diagnosis of glycosuria.

Investigation of suspected type 1 diabetes in newly diagnosed adults, **Flowchart 12.1**.

Box 12.3: Differential diagnosis of glycosuria.

- Glycosuria with hyperglycemia:
  - Endocrine disorders: Diabetes mellitus, acromegaly, Cushing's syndrome, hyperthyroidism, hyperadrenocorticism, functioning α- or β-cell pancreatic tumors, and pheochromocytoma
  - Nonendocrine diseases: Increased intracranial tension (brain tumor or hemorrhage), liver disorders, drugs (e.g., corticosteroids, adrenocorticotropic hormones, thiazides), and alimentary glycosuria

Glycosuria without hyperglycemia: Renal glycosuria and pregnancy

Differential diagnosis of glycosuria (Box 12.3):

- Normal renal threshold is blood glucose level of 180 mg/dL and at this level, there is no glycosuria. If the blood sugar level exceeds the renal threshold (usually >180–200 mg/dL), the excess glucose will not be reabsorbed into the blood and will be eliminated in the urine as in cases of DM. The presence of detectable amounts of **glucose in urine** is termed as **glycosuria**.
- When there is glycosuria, it should be determined whether it is secondary to hyperglycemia (DM) or renal glycosuria or alimentary (lag storage) glycosuria or any other causes (nondiabetic glycosuria).

Renal glycosuria

Q. Write short note/essay on renal glycosuria and Marble's criteria for diagnosis of renal glycosuria.

- **Definition:** Renal glycosuria is the excretion of glucose in the urine at normal blood glucose concentrations in the absence of any signs of generalized proximal renal tubular dysfunction. There is decreased renal threshold below the normal level of 180 mg/dL for glucose. Renal glycosuria is a benign condition transmitted as an autosomal dominant disorder.
- **Diagnosis of renal glycosuria:** It is based on the Marble's criteria **(Box 12.4)**.

Box 12.4: Marble's criteria for the diagnosis of renal glycosuria.

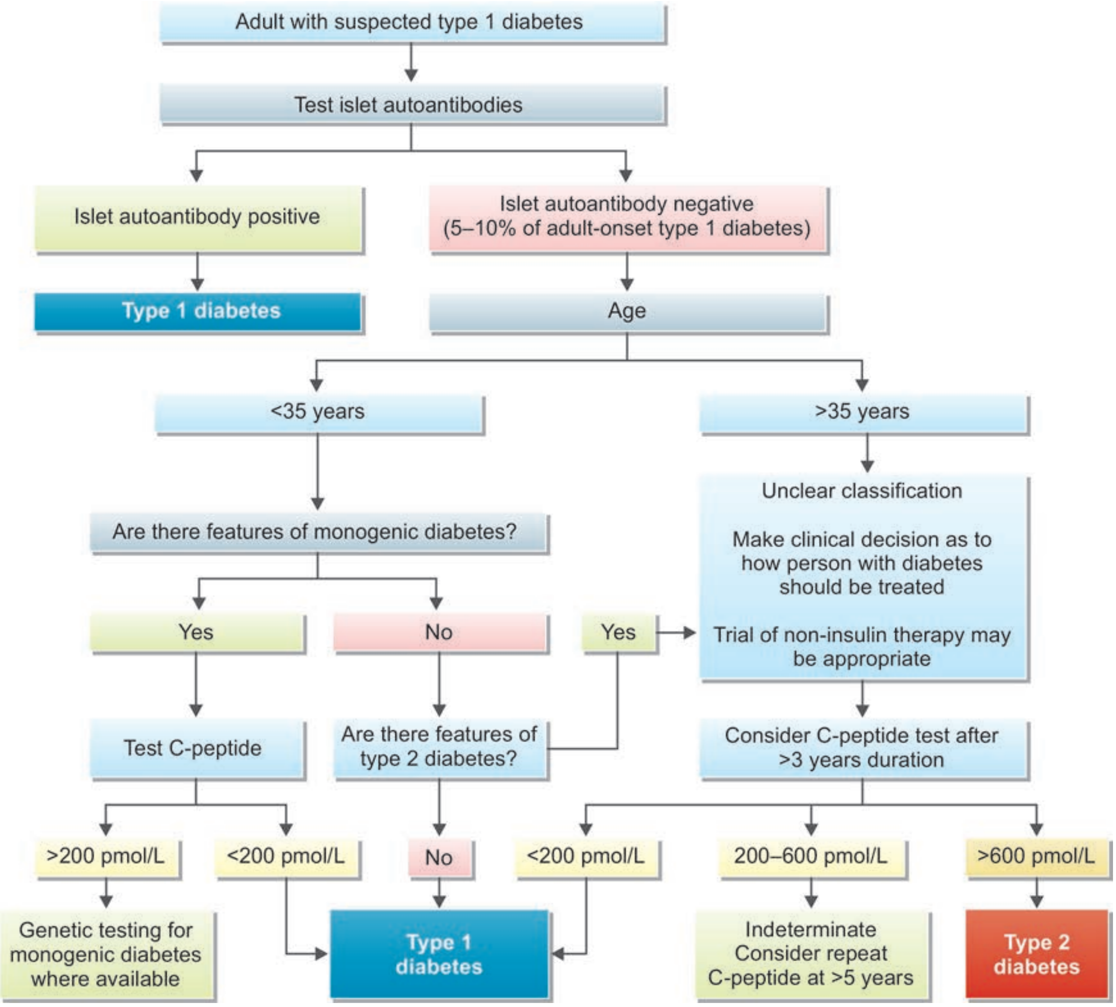
- Constant glycosuria with little fluctuation related to diet
- Normal oral glucose tolerance test (OGTT)
- Identification of urinary reducing substance as glucose
- Normal storage and utilization of carbohydrates

Alimentary (lag storage) glycosuria

Q. Write short note/essay on alimentary (lag storage) glycosuria.

- Alimentary glycosuria is characterized by a transient abnormal rise in blood glucose level following moderate amount of a meal (which normally does not cause appearance of glucose in the urine) and appearance of glucose in the urine. It develops because the blood sugar level exceeds the normal renal threshold (180 mg/dL).
- **Conditions associated** with alimentary glycosuria:
  - Glucose tolerance test reveals a peak at 1 hour above renal threshold (which causes glycosuria), but the fasting and postprandial (i.e., 2 hours after meal) glucose values are normal.
  - Following gastric surgery (e.g., gastrectomy or gastrojejunostomy) with rapid gastric emptying time.
  - Hyperthyroidism
  - Liver diseases
  - Some normal individuals.

FLOWCHART 12.1: Investigation of suspected type 1 diabetes in newly diagnosed adults.



Adult with suspected type 1 diabetes
Test islet autoantibodies
Islet autoantibody positive
Islet autoantibody negative (5–10% of adult-onset type 1 diabetes)
Type 1 diabetes
Age
<35 years
>35 years
Are there features of monogenic diabetes?
Unclear classification
Make clinical decision as to how person with diabetes should be treated
Trial of non-insulin therapy may be appropriate
Yes
No
Yes
Test C-peptide
Are there features of type 2 diabetes?
Consider C-peptide test after >3 years duration
>200 pmol/L
<200 pmol/L
No
<200 pmol/L
200–600 pmol/L
>600 pmol/L
Genetic testing for monogenic diabetes where available
Type 1 diabetes
Indeterminate Consider repeat C-peptide at >5 years
Type 2 diabetes

Oral Glucose Tolerance Test

Q. Write short essay/note on oral glucose tolerance test (OGTT).

Indication: It is not recommended for routine diagnosis of either type 1 or T2DM. This is because FPG identifies the abnormal glucose metabolism.

- In patients where the FPG is in the range of IFG (100–125 mg/dL)
- Diagnosis of gestational DM
- Uncertainty about the diagnosis of diabetes.

Preparation of the patient: Patient should be taking an unrestricted carbohydrate diet for at least 3 days or more prior to the test because carbohydrate-restricted diet reduces glucose tolerance. Patient should be with normal physical activity.

- Oral glucose tolerance test is performed in the morning after patient has fasted overnight (at least 8 hours).
- The patient should rest for at least half an hour before starting the test and refrain from smoking, tea/coffee, or exercise during the test.

Test: A fasting venous sample of blood is drawn to estimate the glucose level.

- Patients are given 75 g of anhydrous glucose dissolved in 250–300 mL of water orally over 5 minutes. Dose in children is 1.75 g of glucose/kg body weight up to a maximum of 75 g. Time of starting glucose is taken as 0 hour.
- A single venous sample of blood is drawn 2 hours after the glucose administration and glucose level is estimated (previously, blood samples were collected at 0.5 hour, 1 hour, 1.5 hour, and 2 hours).
- The criteria for IGT are discussed earlier.

MANAGEMENT OF DIABETES MELLITUS

Q. Long essay on:

- Treatment and monitoring the control of uncomplicated diabetes mellitus.
- Diagnosis and management of type 1 diabetes mellitus (DM)/type 2 DM.
- Diagnosis and treatment of obese patient with type 2 diabetes mellitus (DM).

Diet and Lifestyle Management

Q. Write short essay/note on:

- Dietary management of diabetes mellitus.
- Medical nutrition therapy in diabetes.

Aims of dietary management are given in **Box 12.5**.

Box 12.5: Aims of dietary management in diabetes.

- Achieve good glycemic control
- Reduce hyperglycemia and avoid hypoglycemia
- Reduce the risk of diabetic complications
- Weight management:
  - Weight maintenance for type 1 diabetes mellitus (DM) and nonobese type 2 DM
  - Weight loss for overweight and obese type 2 DM
- Maintain adequate intake of nutrition
- Avoid atherogenic diets or restrict diet for those aggravate complications (e.g., avoid high-protein diet in nephropathy)

Medical Nutrition Therapy

Q. BI8.3 Provide dietary advice for optimal health in childhood and adult, in diabetes mellitus.

Medical nutrition therapy (MNT) should optimally manage the "**ABCs**" of diabetes control: Hb**A**1c, **B**lood pressure, and LDL **C**holesterol.

Medical nutrition therapy for diabetes **has to be individualized** with consideration given to eating habits and lifestyle factors. There must be flexibility in use of ordinary foods for patients and families. The best diet advised is the Mediterranean diet.

Medical nutrition therapy can reduce the HbA1c levels by **0.6–1.4%** if strictly adhered to:

- A **regular pattern of meals** (and snacks) is important to maintain a constant daily intake of carbohydrate and protects against hypoglycemia. Mild deviations in one or two meals do not matter. It is overall long-term dietary pattern that is important.
- Diet in the management of diabetes **varies with the type of disease**.
- In **insulin-dependent** patients and those on intensive insulin regimens, since adjustment of insulin can cover wide variations, the composition of the **diet is not of critical importance**.
- In **noninsulin-dependent** patients, who are not on exogenous insulin, **rigorous adherence to diet** is needed, as the endogenous insulin reserve is limited. The increased demand produced by excess calories or increased intake of rapidly absorbed carbohydrate cannot be met.
- **Caloric content of the diet:** It is first decision to be taken based on the need to gain, lose, or maintain current weight. **Two basic types of diet** used in the treatment of diabetes are: (i) **low-calorie weight reducing diets** and (ii) **weight maintenance diets**. Dietary prescriptions, should be such that there is daily deficit of 500 kcal, provide a realistic diet and produce a weekly weight loss of around 0.5 kg. Calorie recommendations for adults carrying out "average" activity are 36 kcal/kg for men and 34 kcal/kg for women. Recommended diabetic diet should aim at achieving a BMI of 22 kg/m^2. If weight loss cannot be achieved, weight maintenance (rather than gain) is an important goal.
- **Low glycemic index of pulses and pulse-incorporated cereal foods**—including grams and pulses in rice or wheat-based starchy high glycemic index diets reduces the glycemic index and brings satiety along with adequate supply of calories. Meals with mixed sources of cereals, pulses, and legumes contribute to regulation of insulin and glycemic responses.
- **Protein requirement:** Minimal protein requirement for good nutrition is about **0.9 g/kg of body weight/day** (acceptable range is 1.0–1.5 g/kg/day) and should constitute **10–15% of the total calorie intake**. Very low protein diets may retard the progression of diabetic nephropathy. Protein content should be limited to 0.8 g/kg/day or about 10% of daily calories, once nephropathy develops.
- **Fat:** The calories required through carbohydrate and fat must be determined individually. **Restriction of fat is** necessary **if weight loss is desired** because of the high energy value of fat compared to protein and carbohydrate. An **average recommendation** of fat for nonobese diabetic patients and those without hyperlipidemias is **30% or less of total calories** with 10% each as saturated, monounsaturated, and polyunsaturated fats. Monounsaturated fats improve plasma lipid profile with reduction in total and LDL cholesterol without lowering HDL cholesterol in T2DM patients.
- **Carbohydrate:** After choosing the protein and fat content, the remaining calories are to be derived from carbohydrate. It should **constitute 50–55% of the daily caloric intake**, of which significant amount should be in the form of nonstarch

polysaccharide, as dietary fiber. Foods with higher fiber content have a lower glycemic index. **Restrict mono- and disaccharides** (fructose, sucrose, and glucose). The nonnutritive sweeteners such as saccharin, aspartame, sucromate, and acesulfame K are used to reduce energy intake without loss of palatability.

- **Fiber and diabetes mellitus**—increasing the intake of dietary fibers is known to have a favorable effect on the overall metabolic health. Fiber-rich foods contain complex carbohydrates that are resistant to digestion and thereby reduce glucose absorption and insulin secretion.
- **Alcohol consumption:** It accounts for extra calories and has tendency to inhibit gluconeogenesis. Thus, it may potentiate the hypoglycemic action of sulfonylureas and insulin. In addition, alcohol predisposes toward the development of lactic acidosis in patients taking metformin. Hence, it should be best avoided. Recommended intake of various nutrients in diabetic patients is presented in **Table 12.7**.

Pattern of distribution of calories is presented in **Table 12.8**.

Exercise

Advantages: Exercise **improves insulin sensitivity, reduces fasting and postprandial glucose**, and has **metabolic, cardiovascular, and psychological benefits** in diabetic patients.

Based on all available evidence, the ADA and the IDF recommend a total of at least 150 minutes of moderate-intensity physical activity per week that can be a combination of aerobic activities (such as walking or jogging) or resistance training.

Aerobic exercise—adults with diabetes are encouraged to decrease sedentary time and to perform 30–60 minutes of moderate-intensity aerobic activity on most days of the week. Shorter-duration, intensive exercise may be appropriate for physically fit individuals.

Resistance training—in the absence of contraindications (e.g., moderate-to-severe proliferative retinopathy, severe coronary artery disease), people with type 2 diabetes should also be encouraged to perform resistance training (exercise with free weights or weight machines) at least twice per week. Goals of therapy are presented in **Table 12.9**.

TABLE 12.7: Recommended intake of various nutrients in diabetic patients.

Nutrients	*Recommended intake*
Carbohydrate	~50–60% of total calories
Protein	15–20% of total calories
Total fat	25–35% of total calories
Saturated fat	<10% of total calories (<7% in dyslipidemia)
Polyunsaturated fat	~10% of total calories
Monounsaturated fat	Up to 20% of total calories
Cholesterol	<300 mg/day (<200 mg/day in dyslipidemia)
Total calories	➤ Adjust based on age, weight, and height ➤ Sedentary individuals: 30 kcal/kg/day ➤ Moderately active individual: 35 kcal/kg/day ➤ Heavily active individuals: 40 kcal/kg/day

TABLE 12.8: Pattern of distribution of calories.

Percentage of total calories (%)	*Provision for*
20	Breakfast
35	Lunch
15	Late evening feed
30	Dinner

TABLE 12.9: Treatment goals for adults with diabetes.

Index	*Goal*
Glycemic control [glycated hemoglobin (HbA1c)]	<7.0%
Preprandial capillary plasma glucose	3.9–7.2 mmol/L (70–130 mg/dL)
Peak postprandial capillary plasma glucose	<10.0 mmol/L (<180 mg/dL)
Blood pressure	<130/80 mm Hg
Lipids	
➤ Low-density lipoprotein	<2.6 mmol/L (100 mg/dL)
➤ High-density lipoprotein	>1 mmol/L (40 mg/dL) in men and >1.3 mmol/L (50 mg/dL) in women
Triglycerides	<1.7 mmol/L (150 mg/dL)

Cardiovascular Risk Factor Management

In addition to glycemic control, vigorous cardiac risk reduction (smoking cessation; blood pressure control; reduction in serum lipids with a statin; diet, exercise, and weight loss or maintenance; and antiplatelet therapy aspirin for those with established atherosclerotic cardiovascular disease) should be a top priority for all patients with type 2 diabetes.

ORAL HYPOGLYCEMIC (GLUCOSE-LOWERING) DRUGS

Q. 11.16 Discuss and describe the pharmacologic therapies for diabetes, their indications, contraindications, adverse reactions, and interactions of drugs used in diabetes.

Agents used for treatment of type 1 and type 2 diabetes are listed in **Table 12.10**.

Based on their mechanisms of action, oral hypoglycemic drugs are subdivided into agents that increase insulin secretagogues, reduce glucose production, increase insulin sensitivity, enhance glucagon-like peptide-1 (GLP-1) action, or promote urinary excretion of glucose. Various categories of oral hypoglycemic drugs are listed in **Table 12.10**.

TABLE 12.10: Agents used for treatment of type 1 and type 2 diabetes.

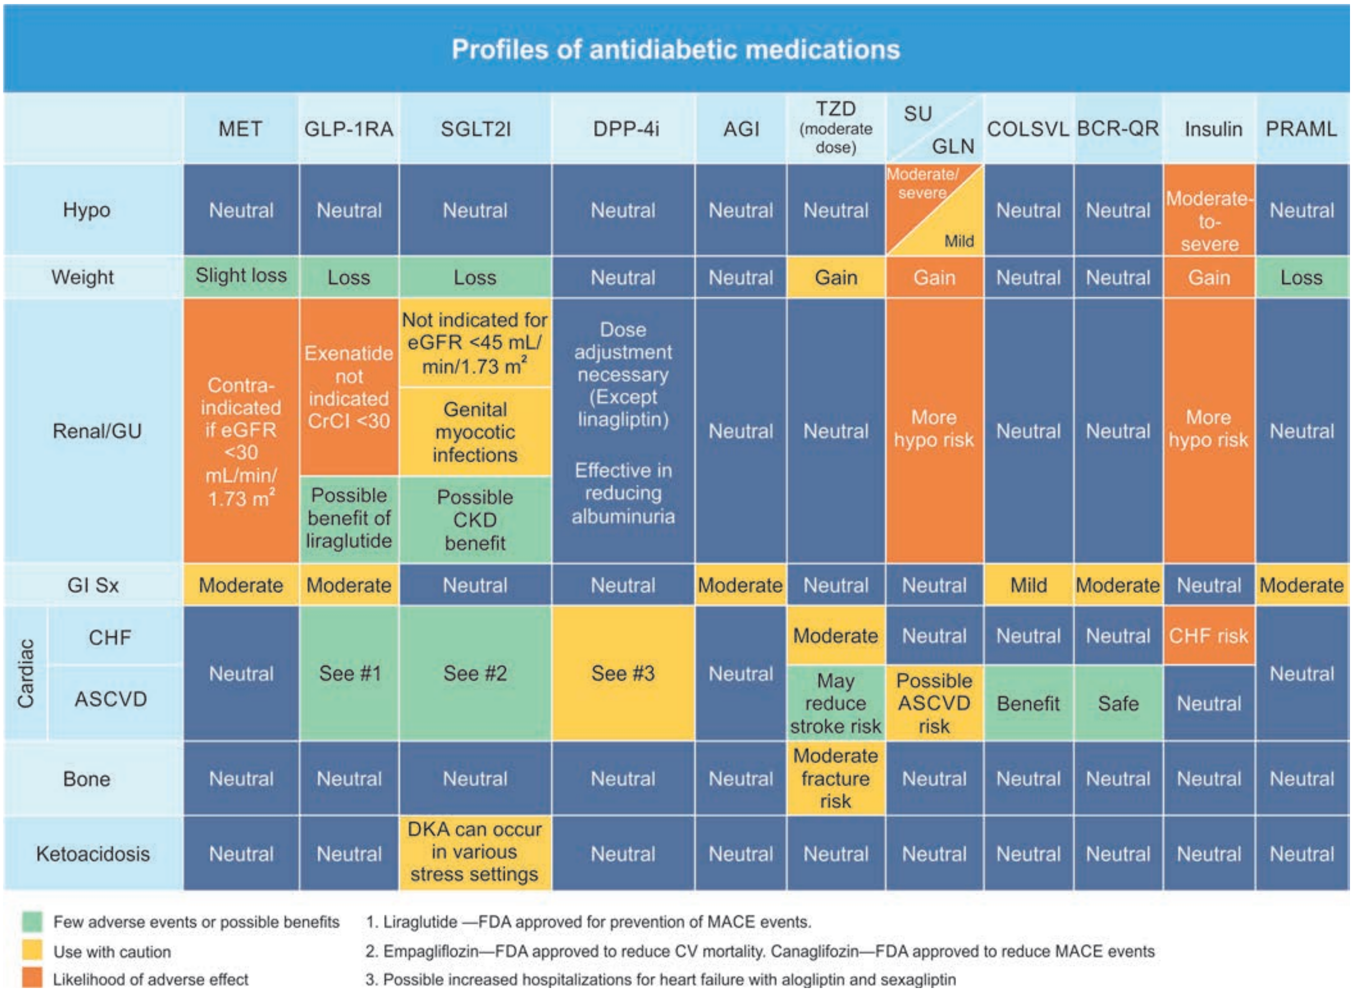
	Mechanism of action	*Examples*	*HbA1c reduction (%)*	*Specific advantages*	*Specific disadvantages*
Oral					
Biguanides	Hepatic glucose production	Metformin	1–2	Weight neutral/ mild weight loss do not cause hypoglycemia, inexpensive	Diarrhea, nausea, lactic acidosis, and vitamin B_{12} deficiency (0.5%)
Insulin secretagogues: Sulfonylureas	Insulin secretion	Glibenclamide (glyburide), glipizide, gliclazide, and glimepiride	1–2	Inexpensive	Hypoglycemia, weight gain, and sulfonamide allergies
Insulin secretagogues: Nonsulfonylureas	Insulin secretion	Repaglinide, nateglinide, and mitiglinide	1–2	Short onset of action, lower post-prandial glucose	Hypoglycemia
Insulin secretagogues: Dipeptidyl peptidase-4 inhibitors	Prolong endogenous GLP-1 action	Saxagliptin, sitagliptin, vildagliptin, linagliptin, teneligliptin, and evogliptin	0.5–0.8	Do not cause hypoglycemia	Nasopharyngitis, meniscus lesions, headache, contact dermatitis, osteoarthritis, and tremor
α-glucosidase inhibitors	↓GI glucose absorption	Acarbose, miglitol, and voglibose	0.5–0.8	Reduce postprandial glycemia	GI flatulence, liver function abnormalities, and contraindicated in kidney disease, inflammatory bowel disease
Thiazolidinediones *Contraindication: CHF and liver disease*	↓ Insulin resistance and ↑ glucose utilization	Rosiglitazone and pioglitazone	0.5–1.4	Lower insulin requirements	Peripheral edema, CHF, weight gain, fractures, macular edema; rosiglitazone may increase cardiovascular risk
Sodium-glucose cotransporter 2 (SGLT2) inhibitors	Help eliminate glucose in the urine	Canagliflozin, dapagliflozin, empagliflozin, and remogliflozin	0.4–1.1	No hypoglycemia and weight loss	Genital and urinary infections
Bile acid sequestrants					
Bile acid sequestrants *Contraindications: Elevated plasma triglycerides*	Bind bile acids, mechanism of glucose lowering is not known	Colesevelam	0.5		Constipation, dyspepsia, abdominal pain, nausea, triglycerides interfere with absorption of other drugs, and intestinal obstruction
Parenteral					
Insulin	↑Glucose utilization, ↓hepatic glucose production, and other anabolic actions	*Refer* **Table 12.14**	Not limited	Known safety profile	Injection, weight gain, and hypoglycemia
GLP-1 receptor agonists *Contraindications: Renal disease, agents that also slow GI motility*	↑Insulin, ↓glucagon, slow gastric emptying, and satiety	Exenatide and liraglutide	0.5–10	Weight loss, do not cause hypoglycemia	Injection, nausea, risk of hypoglycemia with insulin secretagogues, pancreatitis, and renal failure
Amylin agonists *Contraindication: Agents that also slow GI motility*	Slow gastric emptying, ↑glucagon	Pramlintide	0.25–0.5	Reduce postprandial glycemia and weight loss	Injection, nausea, and risk of hypoglycemia with insulin
Medical nutrition therapy and physical activity	↓Insulin resistance, ↑insulin secretion	Low-calorie, low-fat diet and exercise	0.6–1.4	Other health benefits	Compliance difficult, long-term success low

(CHF: Congestive heart failure; GI: Gastrointestinal; GLP-1: Glucagon-like pepetide-1; HbA1c: Glycated hemoglobin)

Biguanides-Metformin

Q. Write short essay/note on metformin.

- It activates cyclic adenosine monophosphate (AMP) kinase and inhibits mitochondrial glycerol-3-phosphate dehydrogenase.



Profiles of antidiabetic medications

		MET	GLP-1RA	SGLT2I	DPP-4i	AGI	TZD (moderate dose)	SU / GLN	COLSVL	BCR-QR	Insulin	PRAML
Hypo		Neutral	Neutral	Neutral	Neutral	Neutral	Neutral	Moderate/ severe Mild	Neutral	Neutral	Moderate-to-severe	Neutral
Weight		Slight loss	Loss	Loss	Neutral	Neutral	Gain	Gain	Neutral	Neutral	Gain	Loss
Renal/GU		Contra-indicated if eGFR <30 mL/min/1.73 m^2	Exenatide not indicated CrCl <30 Possible benefit of liraglutide	Not indicated for eGFR <45 mL/min/1.73 m^2 Genital myocotic infections Possible CKD benefit	Dose adjustment necessary (Except linagliptin) Effective in reducing albuminuria	Neutral	Neutral	More hypo risk	Neutral	Neutral	More hypo risk	Neutral
GI Sx		Moderate	Moderate	Neutral	Neutral	Moderate	Neutral	Neutral	Mild	Moderate	Neutral	Moderate
Cardiac	CHF	Neutral	See #1	See #2	See #3	Neutral	Moderate	Neutral	Neutral	Neutral	CHF risk	Neutral
	ASCVD						May reduce stroke risk	Possible ASCVD risk	Benefit	Safe	Neutral	
Bone		Neutral	Neutral	Neutral	Neutral	Neutral	Moderate fracture risk	Neutral	Neutral	Neutral	Neutral	Neutral
Ketoacidosis		Neutral	Neutral	DKA can occur in various stress settings	Neutral	Neutral	Neutral	Neutral	Neutral	Neutral	Neutral	Neutral

🟩 Few adverse events or possible benefits
🟨 Use with caution
🟧 Likelihood of adverse effect

1. Liraglutide —FDA approved for prevention of MACE events.
2. Empagliflozin—FDA approved to reduce CV mortality. Canagliflozin—FDA approved to reduce MACE events
3. Possible increased hospitalizations for heart failure with alogliptin and sexagliptin

FIG. 12.7: Profile of antidiabetic agents.

(ASCVD: Atherosclerotic cardiovascular disease; CHF: Congestive heart failure; CKD: chronic kidney disease; CrCl: Creatinine clearance; DKA: Diabetic ketoacidosis; DPP-4i: Dipeptidyl peptidase-4 inhibitor; eGFR: Estimated glomerular filtration rate; FDA: Food and Drug Administration; GLP-1RA: Glucagon-like peptide-1 receptor agonist; MACE: Major adverse cardiovascular event; MET: Metformin; SGLT2i: Sodium-glucose cotransporter 2 inhibitor; SU: Sulfonylurea; TZD: Thiazolidinedione)

- It reduces both fasting level of blood glucose and the degree of postprandial hyperglycemia in patients with type 2 diabetes, but has no effect on normal subjects. It is thought to act by inhibiting the hepatic gluconeogenesis.
- Metformin is known to downregulate the hepatic glucose production, acts on the gut to increase glucose utilization, enhances insulin, increases GLP-1, and alters the microbiome.
- Reduces HbA1c by 1.5–2%.
- It is particularly useful in obese patients or those patients who are not responding optimally to maximal doses of sulfonylureas.
- Hypoglycemia does not occur with therapeutic doses of metformin, which permits its description as a "euglycemic" drug rather than an oral hypoglycemic agent (OHA).
- Metformin is not indicated for patients with type 1 diabetes.

Contraindications for metformin are given in **Box 12.6**.

Box 12.6: Contraindications for metformin.

- Malabsorption or GI disturbances/GI intolerance
- Low BMI <21 kg/m^2, marked weight loss
- Organ failure: Creatinine: >1.4 mg/dL, eGFR <30 mL/min/1.73 m^2
  - Liver failure: Acute/chronic
  - Cardiac failure, hypotension/sepsis
- Active vitamin B_{12} deficiency
- Metabolic acidosis

(BMI: Body mass index; eGFR: Estimated glomerular filtration rate; GI: Gastrointestinal)

Insulin Secretagogues (Table 12.11)—Agents that Affect the ATP-sensitive K$^+$ Channel

Sulfonylureas

Q. Write short essay/note on sulfonylureas and name newer sulfonylureas.

They specifically bind to a receptor that closes an ATP-sensitive potassium channel of the pancreatic β-cell, thus depolarizing the cell membrane. This results in an influx of extracellular calcium through voltage-gated calcium channels, which causes insulin granules to move toward the cell surface, facilitating exocytosis. Thus, sulfonylureas have an insulinotropic effect on pancreatic β-cells.

The sulfonylureas are most appropriate for use in nonobese mild type 2 diabetes. In obese mild diabetics and others with peripheral insensitivity to levels of circulating insulin, primary emphasis should be on weight reduction. However, concerns of modest weight gain and moderate-to-severe hypoglycemia and cardiovascular risk limit their clinical benefits. As a consequence of closure of cardiac KATP channel, the use of sulfonylureas have also been related to adverse cardiovascular effects due to impaired hypoxic coronary vasodilation during increased oxygen demands such as acute myocardial ischemia.

They can reduce fasting sugars by 40–70 mg/dL and HbA1c by 1–2% by immediate action.

TABLE 12.11: Properties of insulin secretagogues.

Class/Genetic name	*Daily dosage in milligrams (mg)*	*Duration of action in hours*
Sulfonylureas		
Glimepiride	1–8	24
Glipizide	5–40	12–18
Glipizide (extended release)	5–20	24
Glyburide/glibenclamide	1.25–20	12–24
Glyburide (micronized)	0.75–12	12–24
Nonsulfonylureas (Meglitinides)		
Repaglinide	0.5–16	2–6
Nateglinde	180–360	2–4
Glucagon-like peptide-1 (GLP-1) agonist		
Exenatide	0.01–0.02	4–6
Liraglutide	0.6–1.8	12–24
Dipeptidyl peptidase-4 inhibitors		
Saxagliptin	2.5–5	12–16
Sitagliptin	100	12–16
Vildagliptin	50–100	12–24

First generation: Tolbutamide and chlorpropamide.

Second generation: Glibenclamide (glyburide), glipizide, gliclazide, and glimepiride.

Third generation: Glimepiride.

- Glibenclamide should be taken about half an hour before meals, since rapid absorption is delayed when the drug is taken with food. Most sulfonylureas act via the 140 kDa part of the receptor while glimepiride acts via 65 kDa part of the receptor, hence has better cardiovascular safety.
- Sulfonylureas, particularly gliclazide-modified release (MR) and glimepiride, have a lower risk of hypoglycemia and are preferred in South Asian T2DM patient.

Contraindications to sulfonylureas

Hypersensitivity, renal insufficiency is a relative contraindication (glipizide and gliclazide are preferred, glibenclamide is avoided), hepatic insufficiency, type 1 DM, and DKA.

Nonsulfonylureas—Meglitinides

- **Repaglinide and nateglinide** are not sulfonylureas, but interact with the ATP-sensitive potassium channel. Owing to their short half-life, these are given with each meal or immediately before to reduce meal-related glucose excursions.
- **Advantages of meglitinides:** Flexibility in mealtime dosing—"Ramzan" drug, no significant increase in body weight, can be utilized in mild-to-moderate renal failure, and lesser hypoglycemia.

Agents that Enhance Glucagon-like Peptide-1 Receptor Signaling—Incretin-based Therapy

- The **incretin effect** is defined as the increased stimulation of insulin secretion caused by oral administration of glucose.
    - Two intestinal peptide hormones (incretin hormones) namely—**glucose-dependent insulinotropic polypeptide (GIP)** and GLP-1 have a potentiating effect on secretion of insulin by pancreas. In response to food, GIP is secreted by the K-cells in the duodenum and **GLP-1** by the L-cells of the ileum.
    - These hormones act on their receptors present on islet cells of pancreas and stimulate insulin secretion in response to food. This stimulation of insulin secretion by the gut is referred to as the intestinal secretion of insulin or incretin effect.
    - **The insulin secretion is markedly greater in response to an oral than to an intravenous glucose challenge.**

- **Glucagon-like peptide-1 analogs:**
  - The injectable GLP-1 analogs such as liraglutide, exenatide, lixisenatide, semaglutide , tirzepatide, dulaglutide, and albiglutide imitate the effects of endogenous GLP-1, thereby stimulating pancreatic insulin secretion in a glucose-dependent fashion, suppressing pancreatic glucagon output, slowing gastric emptying, and decreasing appetite.
  - Their main advantage is weight loss, which can be significant in some of the patients.
  - Limiting side effects of these agents are nausea and vomiting, particularly early in the course of treatment.
  - Chances of pancreatitis and pancreatic and thyroid cancer are a matter of concern.

Dipeptidyl Peptidase-4 inhibitors, Gliptins

Q. Write a short note on dipeptidyl peptidase-4 (DPP-4) inhibitors/vildagliptin.

- An alternative approach to the use of GLP-1 analogs is to inhibit DPP-4 to conserve endogenous GLP-1. DPP-4 enhances the incretin effect.
- The enzyme DPP-4 rapidly inactivates GLP-1. Inhibition of this enzyme, thus, potentiates the effect of endogenous GLP-1 secretion.
- **Drugs available: Linagliptin (5 mg OD), saxagliptin (5 mg OD), alogliptin, sitagliptin (100 mg OD), vildagliptin (50 mg OD/BD), teneligliptin (20–40 mg), and evogliptin (5 mg OD)** are oral agents. They are most effective in the early stages of T2DM when insulin secretion is relatively preserved. They are recommended for second-line use in combination with metformin or a sulfonylurea.
- They have a moderate effect in lowering blood glucose and risk of hypoglycemia is low.
- **Side effects:** Adverse effects (AEs) such as constipation, nasopharyngitis, urinary tract infection, myalgia, arthralgia, headache, skin reactions (bullous pemphigoid) and dizziness are the commonly reported AEs with the use of these agents. Worsening of heart failure and rare risk for pancreatitis have been reported.
- **Teneligliptin** is a newer, more potent DPP-4 inhibitor which is safe in renal failure.

α-Glucosidase Inhibitors

Q. Write short essay/note on α-glucosidase inhibitors/acarbose.

Drugs in this group: Acarbose, miglitol, and voglibose.

Mechanism of action: α-glucosidase is an enzyme present on the brush border of the small intestine. It is needed for the breakdown of oligosaccharides (carbohydrates) into simple sugars (before carbohydrates can be absorbed) in the intestinal lumen.

- α-glucosidase inhibitors **reduce glucose absorption** by inhibiting the enzyme α-glucosidase. This result in poor absorption of carbohydrates, thereby reduces postprandial hyperglycemia.
- They neither affect glucose utilization nor insulin secretion.

Indications: They are useful in the management of patients who develop **significant postprandial hyperglycemia** but otherwise have relatively well-controlled blood glucose levels.

- **Dosage:** Dose of both acarbose and miglitol is 25 mg which is first started with a single dose taken just before evening meal. This can be gradually increased to 50 mg with each meal. Dose of voglibose is 0.2–0.3 mg just before each meal.
- **Major side effects:** These drugs are poorly tolerated and may produce diarrhea, flatulence, and abdominal distension. They are due to increased delivery of unabsorbed oligosaccharides to the large intestine where it undergoes fermentation.
- **Advantages:** They are not as potent as other oral hypoglycemic drugs in lowering the HbA1c, but they are unique because it reduces the postprandial glucose rise even in patients with type 1 DM. They do not produce hypoglycemia.

Thiazolidinediones

Q. Write short essay/note on thiazolidinediones.

Drugs in this group: Thiazolidinediones (more conveniently known as the "glitazones") include **pioglitazone**, rosiglitazone, and troglitazone. Troglitazone and rosiglitazone are withdrawn due to increased incidence of liver failure and increased cardiovascular risk, respectively, in patients using it.

Mechanism of action: Thiazolidinediones reduce insulin resistance by binding to **peroxisome proliferator-activated receptor-γ (PPAR-γ)**.

- Highest levels of the PPAR-γ receptor are found in adipocytes. PPARγ is a nuclear receptor, which regulates transcription of large numbers of genes including those involved in lipid metabolism (promote adipocyte differentiation, reduce hepatic fat accumulation, and promote fatty acid storage) and insulin action.

- TZD molecules can interact with PPAR-α and PPAR-γ isoforms expressed primarily on fatty tissues and skeletal muscle. This leads to activating these receptors and stimulating complexation with another essential constituent–the retinoid X receptor. The triple complex can bind specifically to DNA by peroxisome proliferative response elements (PPRE) and act as a target gene promoter, thus stimulating gene expression.
- This therapeutic method leads to increased adiponectin levels, decreased gluconeogenesis, and increased glucose uptake in the muscle and fat. Adiponectin is a hormone secreted in adipose tissue that regulates glucose concentration by improving insulin sensitivity.

Pioglitazone

Q. Write short note on side effects of pioglitazone.

- **Dosage of pioglitazone:** 15–45 mg/day
- **Combination therapy:** It can be combined with metformin and sulfonylureas
- **Side effects:** It include:
  - Weight gain of 2–3 kg (due to fluid retention as well as increase in adiposity), fluid retention, and heart failure
  - Mild anemia and osteoporosis (increased propensity to bone fractures) and bladder carcinoma
- Maximum effect may be seen only after 3–4 weeks
- Conversely, pioglitazone is known to exert pleotropic effects on cardiovascular event; pioglitazone improves endothelial dysfunction, lowers hypertension, improves dyslipidemia, and lowers circulating levels of inflammatory cytokines and prothrombotic factors
- **Precautions:** Liver function should be periodically monitored as liver dysfunction may develop. It is contraindicated in liver disease and congestive cardiac failure.

Sodium-Glucose Cotransporter 2 Inhibitors

- For example, dapagliflozin (5–10 mg/day), remogliflozin (100 mg BD), empagliflozin (25 mg/day), ertugliflozin (5–15 mg/day), and canagliflozin (100–300 mg/day).
- Sodium-glucose cotransporters (SGLTs) are found in the intestinal mucosa of the small intestine and the proximal tubules of the nephrons.
- They provide insulin-independent glucose lowering by blocking glucose reabsorption in the proximal renal tubule. The capacity of tubular cells to reabsorb glucose is reduced by SGLT2 inhibitors leading to increased urinary glucose excretion and consequently, correction of the hyperglycemia.
- The AEs of SGLT2 inhibitors may include fatigue, hypoglycemia, increased urine output, increased hematocrit, and **mycotic genital or urinary tract infections**.
- Other side effects include hypotension, acute kidney injury, bone fracture, and autoamputations.
- Bring about a reduction in HbA1c by 0.7–1%.
- Dose reduction is needed in renal insufficiency.

The direct effects of SGLT-2i include empagliflozin, dapagliflozin, and canagliflozin to inhibit NHE-1 and late Na^+ in cardiomyocytes. SGLT2 inhibitors are especially useful in patients with heart failure and comorbid type 2 diabetes (T2D) by **reducing the risk of heart failure events** and improve life expectancy among patients with HFrEF. SGLT-2i promotes urinary glucose excretion by inhibiting SGLT-2 on the kidneys, lowers insulin, increases glucagon, and then promotes the increase of ketone bodies through the ketogenic effect of the liver. In addition, SGLT-2i increases urinary sodium excretion, reduces blood volume and blood pressure, and reduces preload and afterload of the heart. These indirect effects on vascular cells (including endothelial cells and macrophages) are shown to reduce arterial stiffness and improve vascular and endothelial functions. Metformin can increase the beneficial effects of SGLT-2i on atherosclerosis.

Other Drugs Used in Diabetes

- **Amylin agonist: Pramlintide** is a synthetic pancreatic hormone amylin. It is to be injected before each meal.
- **Bile acid-binding resins: Colesevelam** is a bile acid sequestrants and acts in the GI tract to reduce glucose absorption. Side effects can include constipation, nausea, and dyspepsia.
- **Dopamine agonist: Bromocriptine** is an ergot-derived dopamine agonist that has been used for the treatment of hyperprolactinemia and Parkinson's disease. A quick-release formulation of bromocriptine is used for the treatment of T2DM. Bromocriptine (up to 4.8 mg daily) as monotherapy or as adjunctive therapy to sulfonylureas was minimally effective in reducing HbA1c. Common side effects include nausea, vomiting, dizziness, and headache.

Hydroxychloroquine: 400 mg once daily, reduces HbA1c by 0.5–0.6%. Mechanism of action is impairing insulin degradation.

Lipase Inhibitors (Orlistat)

It produces weight loss which improves glucose tolerance and slows the rate of progression to type 2 diabetes.

Drugs in Pipeline

- Glucokinase activators: Piragliatin
- Dual PPAR (α and γ) agonists: Aleglitazar
- Chromium (Cr), sodium tungstate, vanadium, proxyfan, and β-sitosterol
- S-Allylcysteine (a natural constituent of fresh garlic)
- Otelixizumab and teplizumab—anti-CD3 monoclonal antibody, are known to stimulate C-peptide levels and reduce insulin requirement in type 1 diabetes
- Recombinant human GAD vaccine—for LADA
- Glimins—Imeglimin is the first in a new tetrahydrotriazine-containing class of oral antidiabetic agents, the glimins. It has been shown to act on the liver, muscle, and pancreatic β-cells to uniquely target the key defects of type 2 diabetes.
- **A bionic or "artificial" pancreas** is an external device or system of devices that mimics the glucose regulating function of a healthy pancreas. Such systems monitor glucose levels and automatically provide insulin and potentially other blood-glucose stabilizing hormones to the body.

INSULIN TREATMENT

Q. **Write short essay/note on:**

- **Role of insulin in the management of diabetes/insulin therapy.**
- **Classify insulins. Give a brief account of the commonly used insulins.**
- **Insulin indication and types/indications for short-, intermediate-, and long-acting insulins.**

Insulin is necessary for all patients with type 1 DM and many patients with T2DM. Goals of insulin therapy are mentioned in **Box 12.7**.

Box 12.7: Goals of insulin therapy.

- Elimination of primary symptoms of hyperglycemia and glycosuria
- Prevention of diabetic ketoacidosis (DKA) and hyperosmolar coma
- Restoration of lost lean body mass
- Improvement of physical performance and sense of well-being
- Reduction of frequent infections
- During pregnancy: Decrease fetal malformation, maternal and fetal morbidity
- Delay, arrest, or prevent macrovascular or microvascular complications

General Indications for Insulin Therapy (Table 12.12)

TABLE 12.12: Indications for insulin therapy.

➢ Type 1 DM ➢ Diabetic ketoacidosis (DKA) ➢ Hyperosmolar hyperglycemic state	Diabetes under following conditions: ➢ Pregnancy (preferably prior to pregnancy) ➢ Acute severe illness needing hospitalization ➢ Perioperative/intensive care unit setting ➢ Patients with acute coronary syndrome [myocardial infarction (MI)] ➢ Patients on high-dose corticosteroids ➢ Inability to tolerate or contraindication to oral antiglycemic agents ➢ Newly diagnosed type 2 diabetes with significantly elevated blood glucose levels (patients with severe symptoms or DKA) ➢ Patient no longer achieving therapeutic goals on combination of antiglycemic therapy

Insulin Preparations

Classification of Insulin Preparations (Table 12.13)

TABLE 12.13: Various ways of classification of insulin preparations.

Basis of classification	*Types*
Source	Bovine, porcine, and human insulins
Purity	Conventional, single peak, and monocomponent insulins
Time course of action	Rapid-, intermediate-, and long-acting insulins
Strength	40 and 100 units/mL
Newer insulin analogs	Glargine, detemir, etc.
Bolus insulin (mealtime or prandial)	Regular insulin, lispro, aspart, and glulisine
Basal insulin	Isophane insulin (NPH), glargine, and detemir

Properties of Various Insulin Preparations

The commonly used insulin preparations and their duration of action are presented in **Table 12.14**.

TABLE 12.14: Duration of action (in hours) of various insulin preparations.

Classes	*Types*	*Onset of effect (hours)*	*Peak effect (hours)*	*Effective duration of action (hours)*
Rapid acting	Insulin analogs: Lispro, aspart, and glulisine	<0.25	0.5–1.5	2–4
Short acting	Regular (crystalline, soluble, and plain)	0.5–1	2–3	3–6
	Semilente	0.5–1	2–6	10–12
Intermediate acting	Isophane insulin (NPH)	2–4	4–10	10–16
	Lente (excess zinc ions)[#]	1–3	6–12	18–24
Long acting	Protamine zinc insulin (PZI)	2–4	14–24	36
	Ultralente	2–4	18–24	36
	Insulin analogs: Glargine and detemir	1–4	None	18–24

[#] Lente (intermediate acting) insulin is mixtures of semilente and ultralente in the ratio of 30:70, respectively.

INSULIN ANALOGS/NEWER INSULINS (TABLE 12.15 AND FIG. 12.8)

Q. Write short note on human insulin analogs and advantages of newer insulins/insulin analogs.

TABLE 12.15: Insulin analogs.

Short acting	*Long acting*
Lispro	Glargine
Aspart	Detemir
Glulisine	Degludec

Insulin analogs are prepared by modifying human insulin and have replaced soluble and isophane insulins, especially type 1 diabetes mellitus. Insulin analogs have more flexibility and convenience. In contrast to soluble insulin (which should be injected 30 minutes before eating), rapid-acting insulin analogs can be given immediately before, during, or even after meals. Long- acting insulin analogs (better than isophane insulin) maintain "basal" insulin levels for up to 24 hours and may be given once daily.

Patients on regular insulin regimens may develop repeated episodes of hypoglycemia between meals (during some part of the day) and particularly at night. Insulin analogs are useful in such patients. The various preparations include:

Insulin Lispro

- It is first human insulin analog produced by recombinant DNA technology utilizing a nonpathogenic strain of *Escherichia coli* (*E. coli*).
- **Glucose-lowering activity:** More rapid onset of action (<15 minutes), early peak (60–90 minutes), and a shorter duration of glucose-lowering activity (<5 hours).
- **Disadvantages:** Because of its short duration of action.
- Patient needs to take this insulin analog just before or after meals.
- **Patients need** additional use of longer-acting insulin to maintain glucose control.

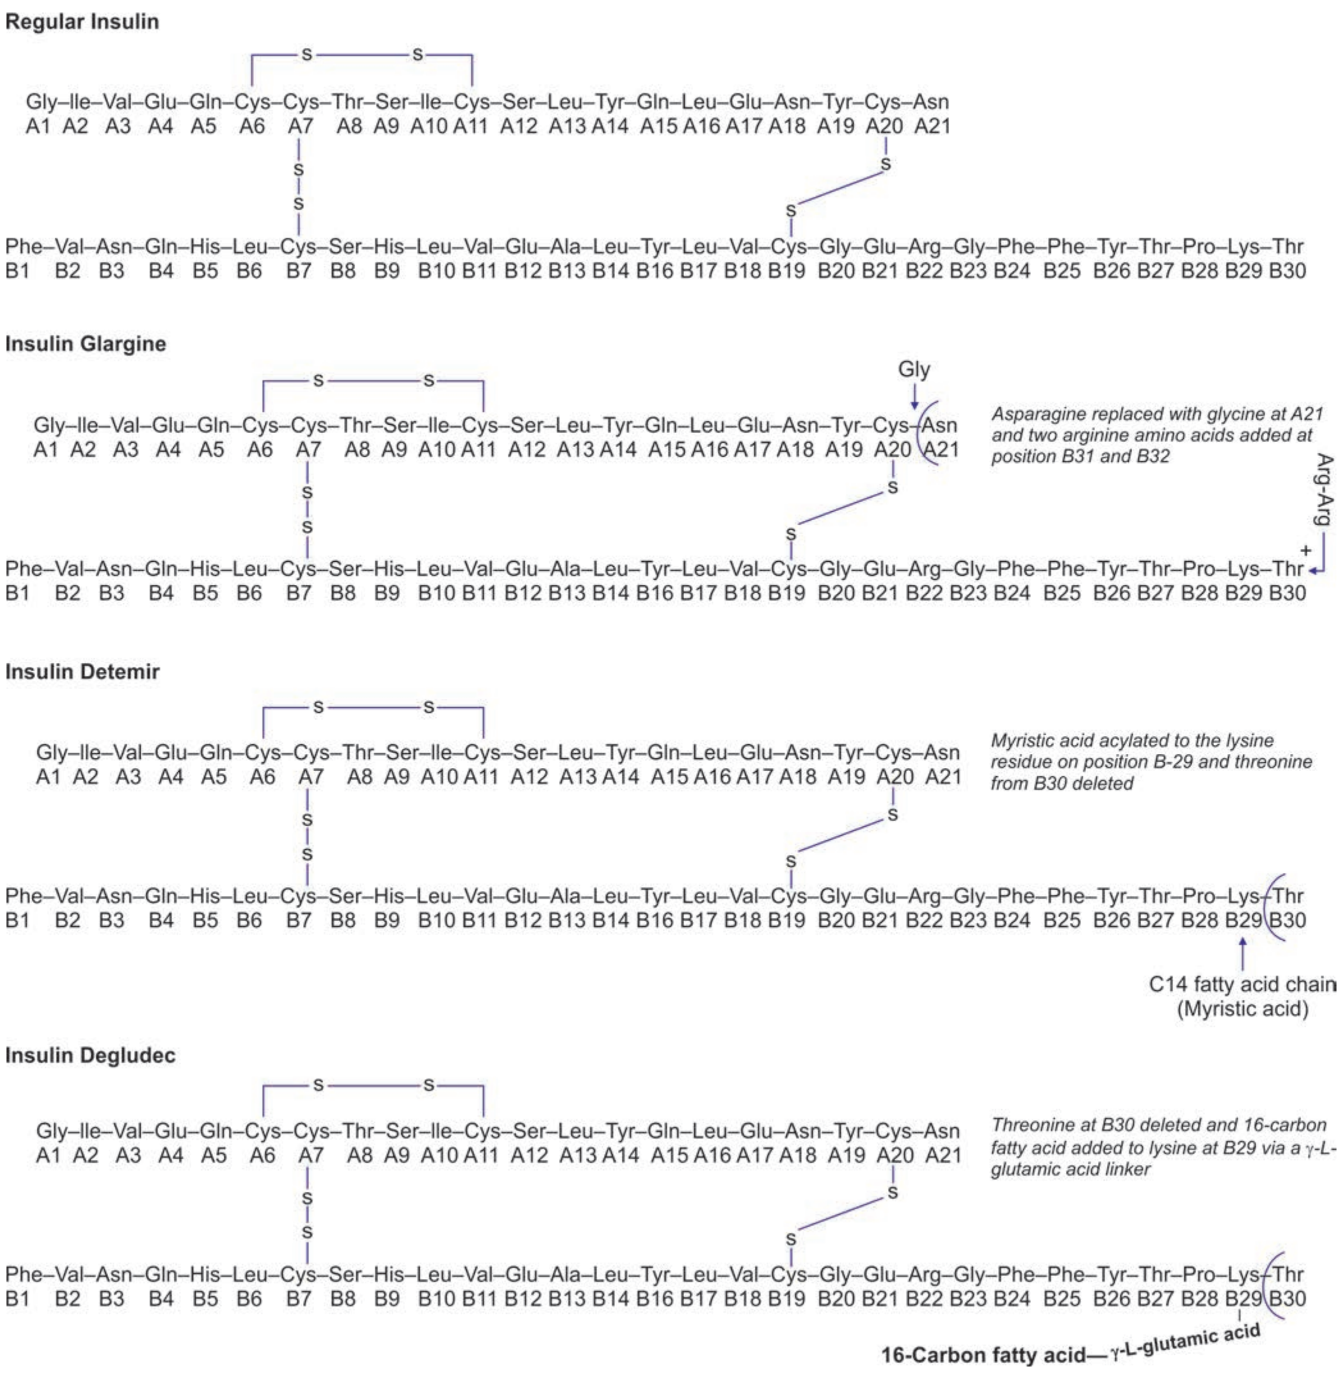
Insulin Aspart and Insulin Glulisine

They are also short-acting insulin analogs similar to lispro.

Fast-acting aspart insulin (FIAsp) is a novel insulin that contains niacinamide and l-arginine resulting in faster initial absorption of insulin aspart (IAsp). FIAsp subcutaneously has been shown to have greater early glucose lowering effect than aspart insulin.

Insulin Glargine

- **It is a human "peakless" bioengineered insulin analog that has a long duration of action and has an acidic pH.**
- **Glucose-lowering activity:** After a lag time of 4–6 hours, the flat peakless effect lasts for 24 hours.
- **Mechanism of action:** After injection into the subcutaneous tissue, **acidic form of insulin becomes neutral and forms microprecipitate**. They **release small amounts** of insulin **very slowly**. It results in a relatively constant concentration for 24 hours without a pronounced peak.
- **Advantages:** It is given **once daily** as subcutaneous injection generally at bedtime. **Hypoglycemia** does not develop.
- **Disadvantages:** As insulin glargine is in acid form, it may cause **increased pain at the injection site**. Its acid nature also **limits its ability to mix with other insulins**.



Regular Insulin

Insulin Glargine

Asparagine replaced with glycine at A21 and two arginine amino acids added at position B31 and B32

Insulin Detemir

Myristic acid acylated to the lysine residue on position B-29 and threonine from B30 deleted

Insulin Degludec

Threonine at B30 deleted and 16-carbon fatty acid added to lysine at B29 via a γ-L-glutamic acid linker

FIG. 12.8A

Insulin Detemir

It is a long-acting, basal soluble human insulin analog and has a neutral pH.

Advantages

- Because of its neutral pH, it causes **least pain** at the site of injection.
- It binds to albumin via its fatty acid chain which allows this analog to remain liquid and soluble following injection. It has **prolonged mode of action** due to its attachment to fatty acid.
- **Neither renal nor hepatic impairment exerts influence** over its pharmacological effects.
- **No gain of weight**.

FIG. 12.8B

FIGS. 12.8A AND B: Amino acid structure of insulin and insulin analogs.

- It is effective when administered once or twice daily and **combined with** the basal **soluble analog** insulin and/or with **oral hypoglycemic drugs** or **premeal short-acting insulin regimen**. Insulin detemir and the rapid-acting analog insulin aspart or lispro closely mimic near-normal insulin profiles and **improve glycemic control than more conventional insulin therapy**.

Insulin Degludec

- **It is a long-acting (>40 hours) human insulin analog.**
- **It forms** soluble multihexamers at the site of subcutaneous injection and releases monomers slowly to give an ultra-long peakless pharmacokinetic (PK) profile. It reduces variability of concentration in the plasma with once-daily regimen.

Advantages of degludec

- **Peakless insulin**
- Excellent improvement in HbA1c and superior FPG reduction
- Less hypoglycemia. Reduction of up to 36% in nocturnal hypoglycemia
- Flexibility: Dosing flexibility: **administration any time on any day.**

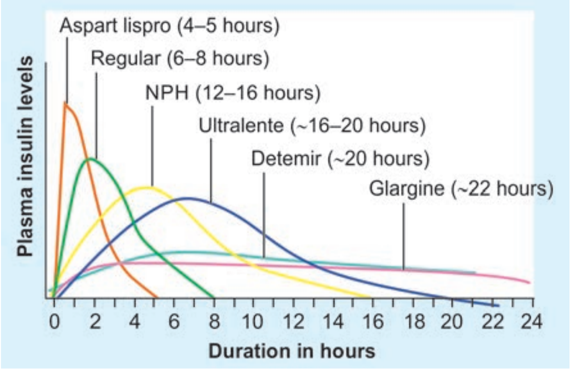

FIG. 12.9: Insulin therapy in diabetes mellitus. Schematic representation of duration of action of insulin profiles.

Schematic representation of duration of action of insulin profiles in diabetes mellitus is depicted in **Figure 12.9**.

Merits and demerits of newer insulin/insulin analogs are given in **Table 12.16**.

TABLE 12.16: Merits and demerits of newer insulin/insulin analogs.

Merits	*Demerits*
➢ Better mimicking of physiological insulin secretion ➢ Better control of glucose levels in the fasting, interdigestive, and postprandial period ➢ Lesser risk of hypoglycemia (especially nocturnal) ➢ No need to be injected half an hour before meals ➢ More predictable action profile independent of dose/site of injection/exercise ➢ Greater flexibility with short-acting analogs ➢ Compliance is improved with long-acting analogs as once a day insulin	➢ No significant different in adverse effects when compared to standard insulins ➢ Worsening retinopathy with lispro [homologous to insulin-like growth factor-1 (IGF-1)] ➢ Carcinogenicity: Concerns over glargine carcinogenicity ➢ High cost

TABLE 12.17: Insulin regimens.

Once-daily insulin regimen	Long-acting peakless insulin + oral hypoglycemic agents
Twice-daily insulin regimen	Intermediate Neutral Protamine Hagedorn (NPH) insulin given twice daily
Sliding scale—premixed/split—mix regimen	Combination of premixed insulin (30:70/50:50) given twice daily or combination of short- and long-acting analogs given three to four times a day
Basal-bolus regimen/multiple daily injection therapy	➢ Basal long-acting or intermediate-acting insulin (NPH, detemir/glargine) once daily usually at night and ➢ Bolus-separate injections of short- or rapid-acting insulin (regular, aspart/lispro/glulisine) at each meal
Continuous subcutaneous insulin infusion/insulin pump therapy	➢ Pump delivers a constant feed of insulin into the body via a cannula subcutaneously ➢ At meal times, an increased burst (bolus) of insulin can be delivered

Inhaled Insulin

- Inhaled human insulin powder was introduced in 2006 and its absorption was through the alveolar surface in the lungs. However, because of adverse effects and cost, it was withdrawn in 2007.
- Inhalation was done with each meal along with single injection of long-acting insulin to provide basal levels of insulin.
- **Side effects:** Cough, dry mouth, sore throat and shortness of breath, and hypoglycemia.
- Example: Afrezza.

Insulin Regimens (Table 12.17)

Three insulin regimens include: (i) conventional insulin therapy, (ii) multiple subcutaneous injections (MSI), and (iii) continuous subcutaneous insulin infusion (CSII). The choice of regimen depends on the degree of glycemic control desired, the severity of insulin deficiency, the patient's lifestyle, and their ability to adjust the insulin dose. Most of type 1 diabetes requires two or more injections of insulin daily. In type 2 diabetes, insulin is usually started as once-daily long-acting insulin, either alone or in combination with OHAs.

Conventional insulin therapy: It is the simplest regimen and used commonly. In this regimen, **intermediate-acting insulin** (lente), with **or without the addition of small amounts of regular insulin**, is injected subcutaneously **once or twice** per day.

- **Insulin mixtures:** In this, intermediate-acting insulin along with small doses of regular insulin is administered to achieve better euglycemic status.
- **Split-lente regimen:** If the total daily requirement of insulin exceeds 50 or 60 units or when there is a need for better control, the intermediate-acting insulin (lente) is administered in two doses/day. Two-thirds of the total required dose is taken before breakfast (7–8 AM) and the remaining one-third before dinner (7–8 PM).

Multiple subcutaneous injections: Insulin is injected subcutaneously several times a day into the anterior abdominal wall, upper arms, outer thighs, and buttocks.

- In this regimen, **intermediate- or long-acting insulin** is administered in the evening as a **single dose**/day together with **regular insulin prior to each meal**.
- It achieves overall control and may reduce the rate of development of long-term complications.
- **Commonly used schedule:** Calculate the total daily dose of insulin required at 0.6–0.7 units/kg body weight.
  - **25% of the calculated dose** is administered as **intermediate-acting insulin at bedtime**.
  - **75% of the calculated dose** is administered as **regular insulin in three divided doses** (40% before breakfast, 30% before lunch, and 30% before dinner).

Continuous subcutaneous insulin infusion/alternative insulin therapies: "Open-loop" systems are small battery-powered portable insulin pumps which provide continuous subcutaneous, intraperitoneal, or intravenous infusion of insulin.

- In this regimen, a **small battery-driven insulin pump** is worn externally and connected to a butterfly needle, which is inserted into the anterior abdominal wall.

- It mimics the physiological basal plus prandial pattern of insulin secretion and can achieve excellent glycemic control. The rate of insulin infusion can be programmed to match the patient's diurnal variation in requirements. About **40% of the total daily required dose** is given **at basal rate; the remainder is given as preprandial boluses**.
- **Advantages:**
  - Ease of taking multiple boluses, if desired.
  - Availability to program the basal rate of insulin delivery, especially useful in dawn phenomenon.
  - Improved control over multiple dose insulin (MDI).
  - Reduced risk of severe hypoglycemia and hypoglycemic attacks can be easily treated.
- **Disadvantages:**
  - Needs a high degree of patient motivation
  - Expensive—high cost
  - Infection at infusion sites
  - High incidence of ketoacidosis
  - Hypoglycemia, especially nocturnal and may be fatal
  - Risk of mechanical malfunctioning.
- Artificial pancreas project **aims to close the loop by using miniaturized glucose sensors to communicate wirelessly with the insulin pump. This would automatically adjust its insulin rate. However, this is not used in clinical practice at present**.

Insulin Delivery Systems

Q. Write short note on newer insulin delivery device.

- **Insulin syringes:** These are available as disposable plastic syringe in various sizes (i.e., 40 U/mL or 100 U/mL). Insulin can be administered using a fine needle (can be reused several times). They can be used easily and has enhanced accuracy.
- **Insulin pen:** An insulin pen holds a prefilled cartridge contain desired type of insulin and has a fine disposable needle that can be changed for each injection. It is suitable for multiple dosing.
- **Implanted insulin pump therapy:** Controlled pumps can be implanted in the peritoneal cavity. Insulin released into the peritoneal cavity is mostly absorbed and delivered into the splanchnic system.
- **External insulin pump therapy:** Portable insulin infusion pump or CSII is alternative insulin delivery devices (refer above).

Complications of Insulin Therapy

Q. Write short essay/note on adverse/side effects (complications) of insulin therapy.

- **Hypoglycemia during insulin treatment:** It is the most common complication of insulin therapy and causes anxiety for both patients and relatives. It occurs due to imbalance between injected insulin and a patient's normal diet, activity, and basal insulin requirement. The risk of hypoglycemia is more before meals, during the night, and during exercise. Irregular eating habits, unusual exertion, and alcohol excess may precipitate hypoglycemic episodes.
- **At the injection site:**
  - A **shallow injection** causes intradermal (rather than subcutaneous) delivery of insulin resulting in painful, red lesions or even scarring. Abscess at injection site is extremely rare.
  - **Local allergic reactions:** It may occur at the injection site early in therapy. These include local itching, erythematous and indurated lesions, and discrete subcutaneous nodules. They usually resolve spontaneously.
  - **Fatty lumps, called as lipohypertrophy,** may develop due to overuse of a single injection site due to lipogenic effects of the injected insulin. It may occur with any type of insulin.
  - **Insulin resistance and anti-insulin antibodies:** Most common cause of mild insulin resistance is obesity. Insulin resistance may be associated with antibodies directed against the insulin receptor.
- **Weight gain:** Many patients may gain weight on insulin treatment, especially if the insulin dose is increased inappropriately. This may be prevented by diet restriction, exercise, and addition of metformin.
- Generalized allergic (urticaria and anaphylactic) reactions are very rare.

Pancreatic Transplantation

Q. Write a short note on pancreatic transplantation.

Other option available in patients with type 1 diabetes mellitus includes whole-pancreas transplantation and islet cell transplantation. Both transplantations can restore normoglycemia without exogenous insulin therapy and survival rates of these patients are consistent with other organ transplantation procedures.

Box 12.8: Summarized management of type 1 diabetes.

- **Insulin therapy**: Oral hypoglycemic agents (OHAs) are ineffective and patient should be started on insulin therapy. It can be split-dose insulin therapy or intensive insulin therapy
- Usually need multiple injections for acceptable glycemic control

Box 12.9: Summarized management of nonobese type 2 diabetes.

- **Lifestyle modification:** If hyperglycemia is mild, following diabetic diet can occasionally restore normal metabolic control
- **Monotherapy:** When diet therapy is not sufficient, a trial of sulfonylurea is often effective in reducing sugar levels
- **Two-drug therapy:** Next step involved combination therapy with metformin, thiazolidinedione/dipeptidyl peptidase-4 inhibitors/glucagon-like peptide-1 receptor agonists/sodium-glucose cotransporter 2 inhibitors can be the next addition for sugar control
- **Insulin therapy:** When patient fails the combination of these three drugs, insulin therapy is indicated. Usually, patients have enough baseline insulin to allow use of single long-acting insulin to take care of sugar control

Box 12.10: Summarized management of obese type 2 diabetics.

- **Weight reduction**: First step is weight reduction to improve tissue sensitivity to insulin
- **Monotherapy**: Among oral hypoglycemic agents (OHAs), monotherapy with **α-glucosidase inhibitors or metformin** may be started, as they are not associated with weight gain or drug-induced hypoglycemia
- **Two-drug therapy**: If metformin therapy is inadequate, **sulfonylurea may be added**
- **Three-drug therapies**: If this combination of metformin and sulfonylurea is ineffective in controlling sugar levels, then **addition of thiazolidinediones**/dipeptidyl peptidase-4 inhibitors/glucagon-like peptide-1 receptor agonists/sodium-glucose cotransporter 2 inhibitors should be considered
- **Insulin therapy** should be instituted, if the combination of these three drugs fails to restore euglycemia. Generally, the sulfonylurea is discontinued when insulin therapy is instituted but the patient can stay on the metformin and thiazolidinediones. Usually, patients have enough baseline insulin to allow use of single long-acting insulin to take care of sugar control

- **Whole-pancreas transplantation:** At present, it is usually performed only in patients with end-stage renal failure who require a combined pancreas/kidney transplantation and in whom diabetes control is particularly difficult (e.g., because of recurrent hypoglycemia).
- **Transplantation of isolated pancreatic islets:** It is performed by harvesting pancreatic islets from cadavers (two or three pancreata are usually necessary). These islets cells are injected into the portal vein and they seed themselves into the liver.
- Management of type 1 diabetes, nonobese type 2 diabetes, and obese type 2 diabetes are summarized in **Boxes 12.8 to 12.10**, respectively.

Q. IM11.17 Outline a therapeutic approach to therapy of T2 diabetes-based on presentation, severity and complications in a cost effective manner.

Metabolic Surgery

It is a recommended treatment option for adults with type 2 diabetes and (1) a BMI of 40 kg/m^2 (or 37.5 kg/m^2 or over in people of Asian ancestry) or (2) a BMI of 35.0–39.9 kg/m^2 (32.5–37.4 kg/m^2 in people of Asian ancestry) who do not achieve durable weight loss and improvement in comorbidities with reasonable nonsurgical methods.

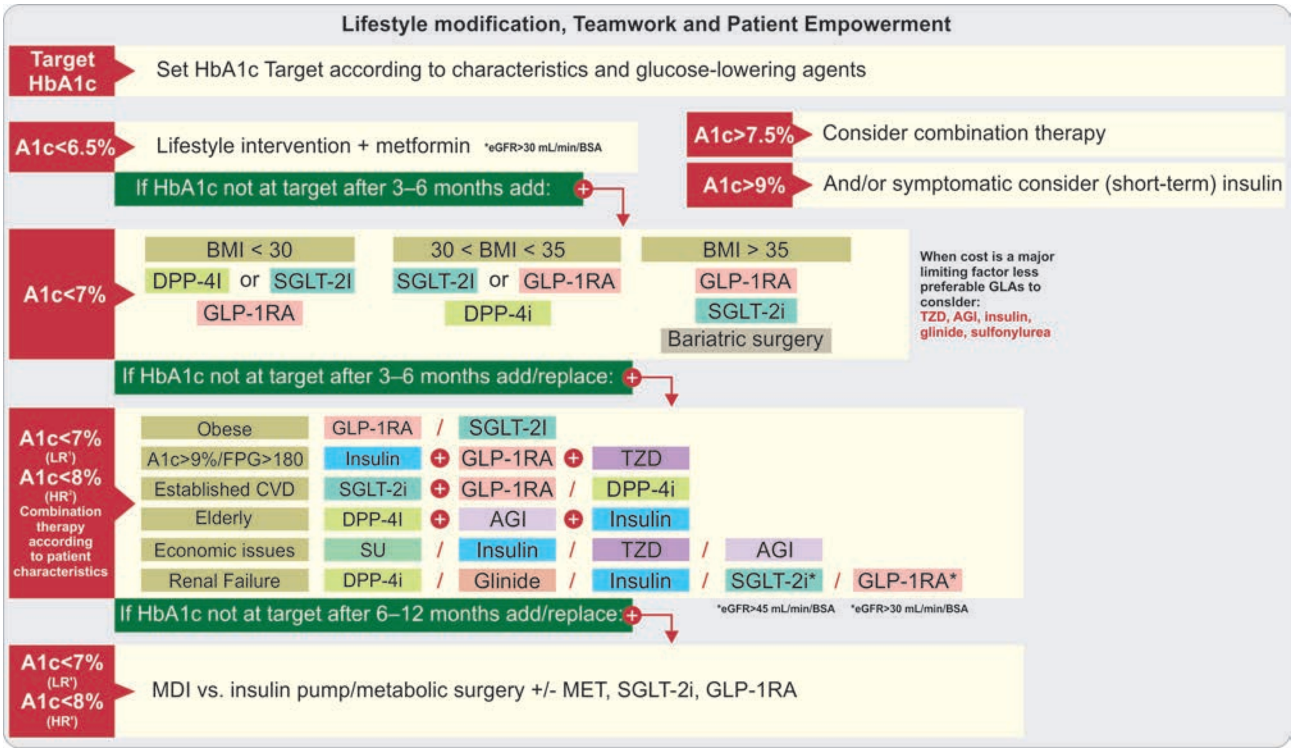
GLYCOSYLATED HEMOGLOBIN AND FRUCTOSAMINE

Q. Write short essay/note on glycosylated hemoglobin (HbA1c).

Guidelines for the treatment of type 2 diabetes is depicted in **Figure 12.10.**

Glycosylated Hemoglobin

- HbA1 is a minor component of adult hemoglobin A (HbA) and its important subgroup is HbAlc. HbAlc has an irreversibly attached glucose and is known as glycosylated hemoglobin.
- **Normal level:** Glycosylated hemoglobin is expressed as a percentage of the normal hemoglobin (standardized range 4–6.1%). In general, the goal of diabetic treatment is to obtain a value below 7%. It should be as close to normal (<6%) as possible without significant hypoglycemia.
- **Significance:** The percentage of HbA1c can be measured and its value provides an excellent assessment of overall state of **glycemic control during the preceding 3 months**.



Lifestyle modification, Teamwork and Patient Empowerment
Target HbA1c
Set HbA1c Target according to characteristics and glucose-lowering agents
A1c<6.5%
Lifestyle intervention + metformin *eGFR>30 mL/min/BSA
If HbA1c not at target after 3–6 months add:
A1c>7.5%
Consider combination therapy
A1c>9%
And/or symptomatic consider (short-term) insulin
A1c<7%
BMI < 30
DPP-4I or SGLT-2I
GLP-1RA
30 < BMI < 35
SGLT-2I or GLP-1RA
DPP-4i
BMI > 35
GLP-1RA
SGLT-2i
Bariatric surgery
When cost is a major limiting factor less preferable GLAs to consider:
TZD, AGI, insulin, glinide, sulfonylurea
If HbA1c not at target after 3–6 months add/replace:
A1c<7% (LR¹) A1c<8% (HR²) Combination therapy according to patient characteristics
Obese
GLP-1RA / SGLT-2I
A1c>9%/FPG>180
Insulin + GLP-1RA + TZD
Established CVD
SGLT-2i + GLP-1RA / DPP-4i
Elderly
DPP-4I + AGI + Insulin
Economic issues
SU / Insulin / TZD / AGI
Renal Failure
DPP-4i / Glinide / Insulin / SGLT-2i* / GLP-1RA*
*eGFR>45 mL/min/BSA
*eGFR>30 mL/min/BSA
If HbA1c not at target after 6–12 months add/replace:
A1c<7% (LR¹) A1c<8% (HR²)
MDI vs. insulin pump/metabolic surgery +/- MET, SGLT-2i, GLP-1RA

FIG. 12.10: Guidelines for the treatment of type 2 diabetes.

(AGI: Alpha-glucosidase inhibitors; BSA: Body surface area; CVD: CV Disease; DPP-4i: DPP-4 inhibitors; eGFR: Estimated glomerular filtration rate; FPG. >180: Fasting plasma glucose.180 mg/dL; HR²: High-risk of hypoglycemia; LR¹: Low-risk of hypoglycemia; MDI: Multiple daily injections; MET: Metformin; SGLT-2i: SGLT2 inhibitors; TZD: Thiazalidinediones).

- **Factors that influence HbA1c level:**
  - **Blood glucose level:** The level of HbA1c is dependent on the prevailing glucose level in the blood (exposure of the red cell to glucose). If young red blood cells (RBCs) are exposed to extremely high blood glucose (>400 mg/dL) for several hours, HbA1c level increases. Thus, in patients with DM, it is useful in assessing the blood glucose control; higher the count, poorer is the control.
  - **Disease associated with altered RBC survival:** Glycation of hemoglobin occurs only when the RBC circulates in serum. Older RBCs have more HbA1c than reticulocytes. Total HbA1c reflects the mixture of both old and younger RBCs. In patients with hemolytic anemia such as thalassemia, the measured HbA1c level will be lower, independent of glycemia. Conversely, if the circulating RBCs are older (e.g., aplastic anemia), then measured HbA1c level will be higher, regardless of glycemic status.
- Although the HbA1c level provides a rapid assessment of glycemic control, blood glucose level should also be tested to know the control.

Glycosylated Plasma Proteins (Fructosamine)

- It may also be measured as an index of diabetic control. It measures glycation of all serum proteins and the major component being **glycosylated albumin**. Since albumin accounts for most of the protein in blood, the measurement of fructosamine, for practical purposes, measures glycated albumin. As albumin has a turnover of about 2 weeks, fructosamine reflects **glycemia over the preceding 2–3 weeks** (shorter period).
- It is **useful in diabetic patients with anemia or hemoglobinopathy and in pregnancy** (when hemoglobin turnover is changeable).

Glucose Management Indicator (GMI) and Time in Range (TIR)

- These measurements are got from the continuous glucose monitoring (CGM) data.
- GMI is calculated based on the average sensor glucose over the last 14 days and provides an approximation of a laboratory-measured HbA1c in some individuals, but it may be higher or lower than actual HbA1c in others. GMI and TIR may be more useful than HbA1c for clinical management because they reflect more recent blood glucose levels and provide more detailed clinical information.

- A typical GMI goal is <53 mmoL/moL (<7.0%). TIR is often taken as 3.9–10 mmol/L (70–180 mg/dL) for most adults and time below range (TBR) as below 3.9 mmol/L (70 mg/dL) (risk alert level), as well as less than 3.0 mmol/L (54 mg/dL) (clinically significant).
- Time in Range (TIR) was recently released and defined the concept of the time spent in the target range between 70 and 180 mg/dL while reducing time in hypoglycemia, for patients using Continuous Glucose Monitoring (CGM). TIR is associated with microvascular complications and a TIR of 70% roughly corresponds to an HbA1c of 53 mmol/moL (7.0%).

COMPLICATIONS OF DIABETES

Classification of complications of diabetes is presented in **Table 12.18**.

Q. Write short essay/note on:

- Classify and enumerate the complications of diabetes.
- Chronic complications of diabetes mellitus.

Acute Complications of Diabetes (Table 12.18)

Q. Write short essay/note on acute complications of diabetes mellitus.

DIABETIC KETOACIDOSIS

Q. 11.23 Describe the precipitating causes, pathophysiology, recognition, clinical features, diagnosis, stabilization, and management of diabetic ketoacidosis.

Diabetic ketoacidosis, a medical emergency, is a state of metabolic decompensation, which occurs due to a severe deficiency of insulin. It is **more common and marked in type 1 diabetes** and is rare but may also occur in type 2 diabetes. It is usually seen in previously undiagnosed DM. Precipitating factors are listed in **Box 12.11**.

Mechanism/Pathogenesis (Fig. 12.11)

Cardinal biochemical features of DKA: (1) hyperglycemia, (2) hyperketonemia (and ketonuria), and (3) metabolic acidosis. DKA develops due to the combined effects by: (1) relative or absolute insulin deficiency and (2) counterregulatory glucagon excess. Other hormones such as catecholamines (e.g., epinephrine), cortisol, and growth hormone are also being produced in excess.

TABLE 12.18: Complications of diabetes.

Acute metabolic complications

- Diabetic ketoacidosis (DKA)
- Hyperosmolar hyperglycemic state (hyperosmolar nonketotic diabetic coma)
- Lactic acidosis
- Hypoglycemia

Chronic (long-term) complications

A. Vascular complications

- **Microvascular**
  - Ophthalmic:
    - Diabetic retinopathy (nonproliferative and proliferative)
    - Cataract
    - Glaucoma
  - Peripheral neuropathy:
    - Sensory
    - Motor
    - Sensory motor
    - Autonomic neuropathy
  - Renal:
    - Nephropathy: Microalbuminuria, macroalbuminuria
    - Chronic kidney disease
  - Foot disease
- **Macrovascular**:
  - Coronary artery disease
  - Peripheral vascular disease
  - Cerebrovascular disease

B. Nonvascular complications

- Gastroparesis
- Infections
- Skin changes (dermatological complications)
- Hearing loss

Box 12.11: Precipitating factors of diabetic ketoacidosis (DKA) in a known patient with diabetes mellitus (DM).

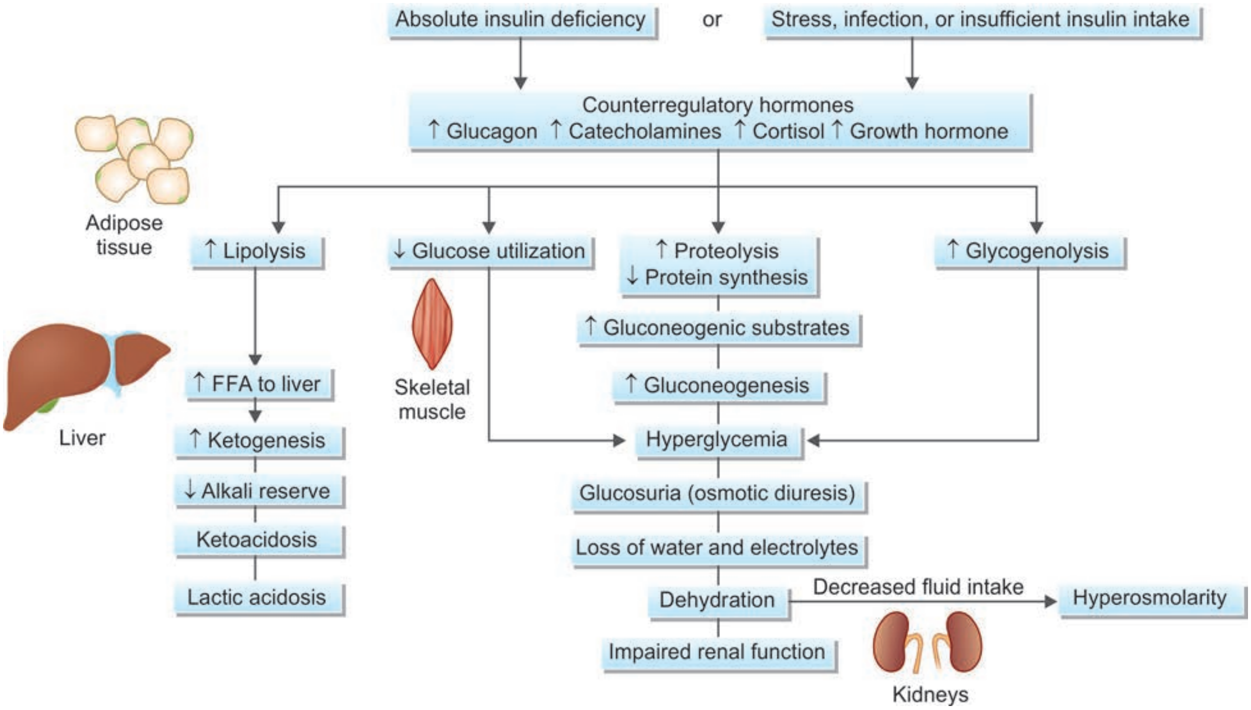
- Infections (pneumonia, urinary tract infections, sepsis, and gastroenteritis)
- Acute pancreatitis
- Alcohol intoxication
- Inadequate insulin
- Infarction (cerebral, coronary, mesenteric, and peripheral)
- Severe stress (e.g., physical, emotional)
- Hyperthyroidism, pheochromocytoma
- Drugs (e.g., thiazides, corticosteroids, cocaine)
- Pregnancy

Consequences of insulin deficiency and glucagon excess

- **Severe hyperglycemia:** The blood glucose levels of 500–700 mg/dL.
- **Diuresis and dehydration:** Hyperglycemia causes a hyperosmolar state, which induces an **osmotic diuresis** leading to volume depletion and **dehydration** (characteristic features of ketoacidosis). There is loss of electrolyte, particularly of sodium and potassium.

Q. Write short essay/note on ketone bodies.

- **Activation of the ketogenic machinery:**
  - **Lipolysis:** Insulin deficiency stimulates lipoprotein lipase, which breaks down fat stores (lipolysis) and increases the FFAs levels in the plasma.



Absolute insulin deficiency
or
Stress, infection, or insufficient insulin intake
Counterregulatory hormones
↑ Glucagon ↑ Catecholamines ↑ Cortisol ↑ Growth hormone
Adipose tissue
↑ Lipolysis
↓ Glucose utilization
↑ Proteolysis
↓ Protein synthesis
↑ Glycogenolysis
↑ Gluconeogenic substrates
Liver
↑ FFA to liver
Skeletal muscle
↑ Gluconeogenesis
↑ Ketogenesis
Hyperglycemia
↓ Alkali reserve
Glucosuria (osmotic diuresis)
Ketoacidosis
Loss of water and electrolytes
Lactic acidosis
Dehydration
Decreased fluid intake
Hyperosmolarity
Impaired renal function
Kidneys

FIG. 12.11: Pathogenesis of diabetic ketoacidosis.
(FFA: free fatty acid)

- **Generation of ketone bodies in liver:** In DKA, hyperglucagonemia (excess of glucagon) alters hepatic metabolism of FFA to favor ketone body formation. This is through activation of the enzyme **carnitine palmitoyltransferase 1**. The FFAs are esterified to fatty-acyl coenzyme A in the liver. In the mitochondria of liver cells, fatty-acyl coenzyme A molecules are oxidized to ketone bodies (**acetoacetic acid, β-hydroxybutyric acid**, and minor amount of acetone). These ketone bodies accumulate in the body fluids.

- **Ketonemia and ketonuria:** When the **rate of production of ketone bodies exceeds the rate of utilization** by peripheral tissues, it results in **ketonemia** and **ketonuria**.
- **Metabolic acidosis:** Acetoacetic acid and β-hydroxybutyric acid are strong acids and are responsible for the acidotic state. If the excretion of ketone bodies in the urinary is compromised by dehydration, it results in **systemic metabolic ketoacidosis (high anion gap)**.

Clinical features of diabetic ketoacidosis

- DKA may present as the initial symptom complex that leads to a diagnosis of type 1 DM for the first time, but more commonly, it develops in patient with already diagnosed DM.
- Clinical features of DKA are those of uncontrolled diabetes with acidosis. Patients typically present with **polyuria, polydipsia**, and other symptoms of progressive hyperglycemia.
- **Other clinical features** include **nausea, vomiting, weakness, weight loss**, lethargy, anorexia, leg cramps, blurred vision, and shortness of breath. Vomiting is an ominous symptom because it precludes oral replacement of fluid losses; severe volume depletion may follow quickly.
- **Abdominal pain** is classically periumbilical and sometimes may be so severe that may be confused with a surgical acute abdomen (such as acute pancreatitis or ruptured viscus).

Physical findings in diabetic ketoacidosis

- Findings secondary to **dehydration and acidosis**: These include **dry skin** and mucous membranes, **reduced jugular venous pressure, tachycardia, hypotension** (postural or supine), cold extremities/peripheral cyanosis, depressed mental function, and **Kussmaul (deep, rapid hyperventilation) respirations**.
- **Fruity** (sickly-sweet) **smell** of ketones on the patient's **breath** allows an instant diagnosis.
- **Hypothermia:** Body temperature is either normal or low in uncomplicated DKA. Presence of fever suggests infection.
- Mental apathy, confusion, psychomotor retardation, hyporeflexia, and hypotonia may be observed.
- Abdominal tenderness.

- **Symptoms and signs of cerebral edema:** Headache, altered sensorium, seizures, bowel/bladder incontinence, papilledema, bradycardia, hypertension, and respiratory arrest.

Complications

Acute gastric dilatation/erosive gastritis, cerebral edema, hyperkalemia/hypokalemia, hypoglycemia, infections, myocardial infarction, mucormycosis, and acute respiratory distress syndrome (ARDS).

Investigations

- **Urine examination:** Shows glucose and ketones.
- **Plasma levels** of following is to be estimated:
  - **Glucose levels** are raised (hyperglycemia) often markedly
  - **Ketone bodies** are raised.
- **Serum electrolytes:**
  - **Potassium** levels are normal or raised in the initial stages despite a total body deficit of potassium. This is because metabolic acidosis shifts potassium from intracellular compartment to extracellular compartment. The levels drop once the treatment is started.
  - **Sodium** levels are usually low, particularly if the patient has repeated vomiting and continued to drink water (pseudohyponatremia).
  - **Bicarbonate** levels are low. Value <12 mmol/L indicates severe acidosis.
  - **Phosphorus** level may be high initially despite a total body deficit of phosphorus.
- **Blood:**
  - **Leukocytosis** invariably occurs in DKA; this represents a stress response and may not necessarily indicate infection.
  - **Arterial blood gas (ABG):** Reveals high anion gap metabolic acidosis.
  - **Blood urea nitrogen (BUN)** is usually raised due to prerenal failure produced from volume depletion.
  - **Infection screen:** Full blood count, blood and urine culture, C-reactive protein, and chest X-ray.
  - **Serum amylase** may be elevated.
- **Electrocardiogram (ECG): To rule out myocardial infarction.**

Diagnostic criteria for DKA (Table 12.19)

Diagnostic criteria for DKA include plasma glucose >250 mg/dL, arterial pH <7.3, serum bicarbonate <15 mEq/L, ketonemia and/or ketonuria, and anion gap of >12 mEq/L (usually present in DKA).

TABLE 12.19: Diagnostic criteria for diabetic ketoacidosis and the hyperosmolar hyperglycemic state.

	Diabetic ketoacidosis (DKA)			*Hyperosmolar hyperglycemic state (HHS)*
Features	***Mild***	***Moderate***	***Severe***	
Mental status	Alert	Drowsy	Stupor or coma	Stupor or coma
Urine or serum ketone bodies	Positive	Positive	Positive	Negative to trace
Plasma glucose level (mg/dL)		>250		>600
Effective serum osmolality (mOsm/kg)		Variable		>320
Arterial pH	7.25–7.30	7.00–7.24	<7.00	>7.30
Serum bicarbonate (mEq/L)	15–18	10–15	<10	>15
Anion gap (mEq/L)	>10	>12	>12	<12

Management

Goals of therapy of diabetic ketoacidosis are given in **Box 12.12**.

Fluid resuscitation (Flowchart 12.2)

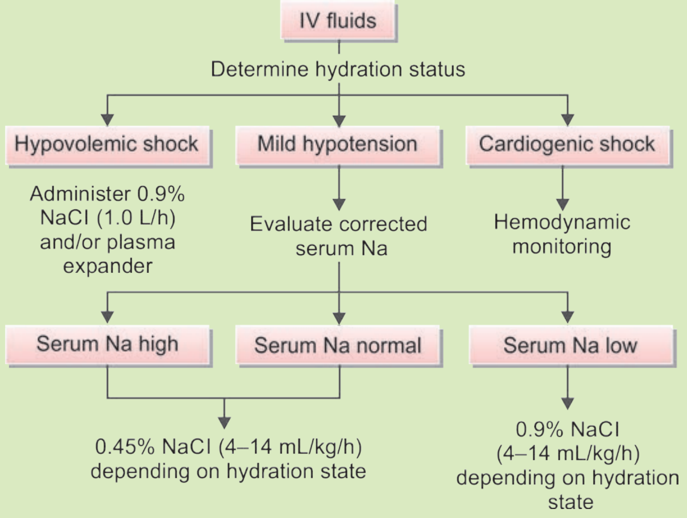
It is a critical part of treating patients with DKA as it is a state of severe dehydration.

- Intravenous solutions to replace extravascular and intravascular fluids and electrolyte losses. The usual fluid deficit is minimum 3–5 L and should be replaced intravenously. They dilute levels of both the glucose and the circulating counterregulatory hormones.
- Fluid itself leads to correction of acidosis to some extent.

Box 12.12: Goals of therapy of diabetic ketoacidosis.

- Rehydration
- Reduction of hyperglycemia
- Correction of electrolyte imbalance
- Correction of acid-base imbalance
- Investigation and correction of precipitating factors
- Treatment of complications

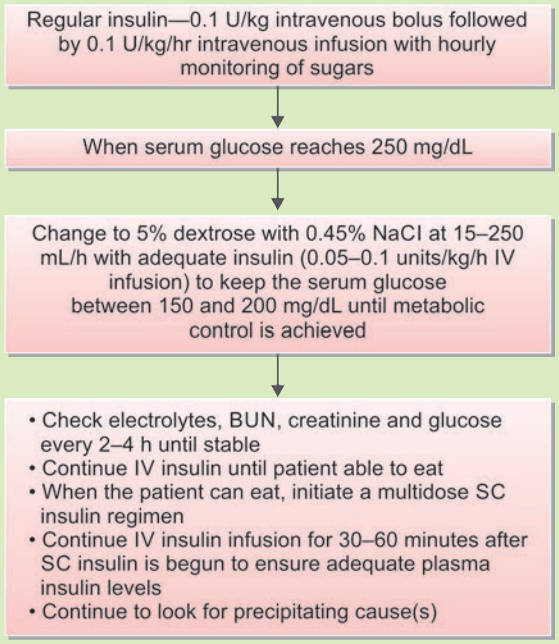
FLOWCHART 12.2: Fluid resuscitation.



IV fluids
Determine hydration status
Hypovolemic shock
Mild hypotension
Cardiogenic shock
Administer 0.9% NaCl (1.0 L/h) and/or plasma expander
Evaluate corrected serum Na
Hemodynamic monitoring
Serum Na high
Serum Na normal
Serum Na low
0.45% NaCl (4–14 mL/kg/h) depending on hydration state
0.9% NaCl (4–14 mL/kg/h) depending on hydration state

(IV: Intravenous; NaCl: Sodium chloride)

FLOWCHART 12.3: Insulin recommendations.



Regular insulin—0.1 U/kg intravenous bolus followed by 0.1 U/kg/hr intravenous infusion with hourly monitoring of sugars
When serum glucose reaches 250 mg/dL
Change to 5% dextrose with 0.45% NaCl at 15–250 mL/h with adequate insulin (0.05–0.1 units/kg/h IV infusion) to keep the serum glucose between 150 and 200 mg/dL until metabolic control is achieved
• Check electrolytes, BUN, creatinine and glucose every 2–4 h until stable
• Continue IV insulin until patient able to eat
• When the patient can eat, initiate a multidose SC insulin regimen
• Continue IV insulin infusion for 30–60 minutes after SC insulin is begun to ensure adequate plasma insulin levels
• Continue to look for precipitating cause(s)

(BUN: Blood urea nitrogen; IV: Intravenous; NaCl: Sodium chloride; SC: Subcutaneous)

Insulin recommendations (Flowchart 12.3)

Short-acting insulin is administered to reverse acidosis and treat hyperglycemia.

Potassium repletion (Flowchart 12.4)

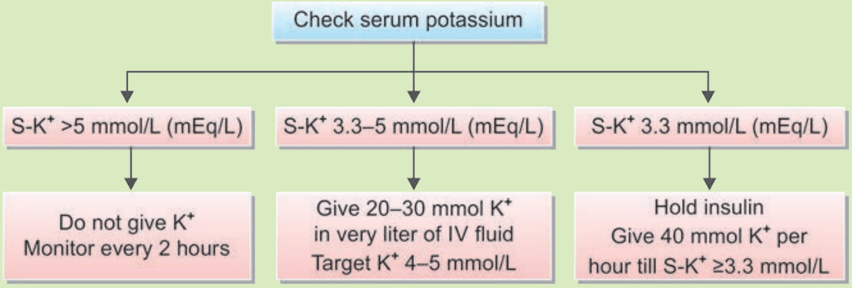
Correction of acid-base balance (Flowchart 12.5)

Its role is controversial and usually not practiced.

Phosphorus repletion: A sharp drop of serum phosphorus can also occur during insulin treatment and no treatment is usually necessary.

Complications of DKA: Mortality is <10%. Death occurs due to infection, thrombosis, cerebral edema, and shock.

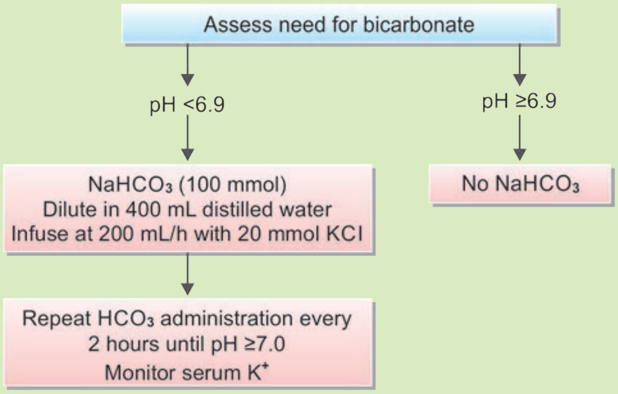
FLOWCHART 12.4: Potassium repletion.



Check serum potassium
S-K^+ >5 mmol/L (mEq/L)
S-K^+ 3.3–5 mmol/L (mEq/L)
S-K^+ 3.3 mmol/L (mEq/L)
Do not give K^+
Monitor every 2 hours
Give 20–30 mmol K^+
in very liter of IV fluid
Target K^+ 4–5 mmol/L
Hold insulin
Give 40 mmol K^+ per hour till S-K^+ ≥3.3 mmol/L

(IV: Intravenous)

FLOWCHART 12.5: Correlation of acid-base balance.



Assess need for bicarbonate
pH <6.9
pH ≥6.9
$NaHCO_3$ (100 mmol)
Dilute in 400 mL distilled water
Infuse at 200 mL/h with 20 mmol KCl
No $NaHCO_3$
Repeat HCO_3 administration every 2 hours until pH ≥7.0
Monitor serum K^+

Box 12.13: Criteria for resolution of diabetic ketoacidosis (DKA).

- Glucose <200 mg/dL
- Serum bicarbonate ≥18 mEq/L
- Venous pH of >7.3
- Plasma osmolality effectively has fallen below 315 mOsmol/kg
- The patient is able to eat

Criteria for resolution of DKA are mentioned in **Box 12.13**.

HYPEROSMOLAR HYPERGLYCEMIC STATE

Q. 11.24 Describe the precipitating causes, pathophysiology, recognition, clinical features, diagnosis, stabilization, and management of hyperosmolar nonketotic state.

- It is **metabolic emergency**, which usually occurs as a complication of **uncontrolled T2DM**. Patients usually present in **middle or later life** (presently it is increasingly seen in younger adults), often with previously undiagnosed diabetes.
- This syndrome has a high mortality rate (>50%).

Characteristics of Hyperosmolar Hyperglycemic State

It is a syndrome characterized by:

- **Severe hyperglycemia** [>30 mmol/L (600 mg/dL)]
- **Hyperosmolality** (serum osmolality >320 mOsm/kg)
- Extreme **dehydration in the absence of significant hyperketonemia** (<3 mmol/L) **or ketoacidosis** (pH >7.3, bicarbonate >15 mmol/L).

Precipitating factors for HHS are listed in **Box 12.14**.

Box 12.14: Precipitating factors for hyperosmolar hyperglycemic state (HHS).

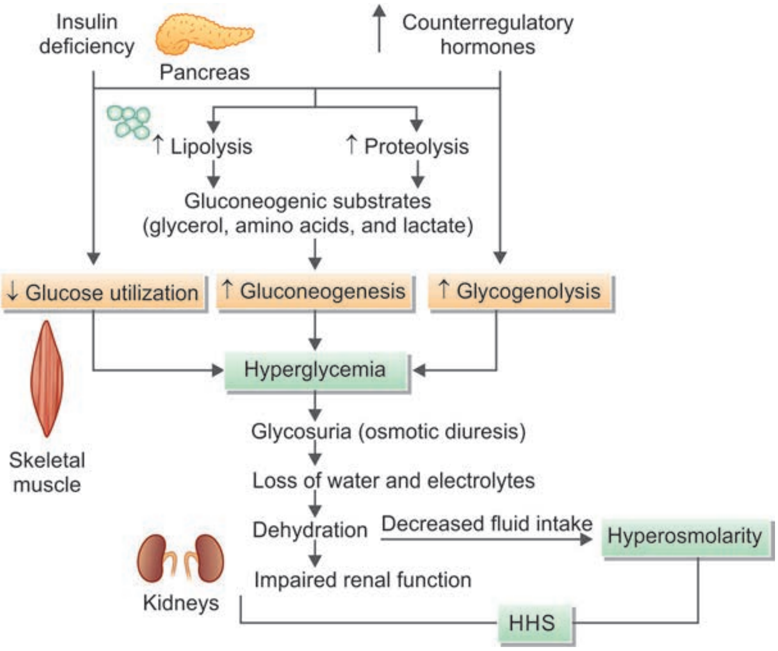
- Infections
- Physical and emotional stress
- Inadequate fluid intake
- Cerebrovascular accidents
- Myocardial infarction
- Concurrent medication, e.g., thiazide diuretics, steroids, immunosuppressive agents, phenytoin, and osmotic agents like mannitol
- Peritoneal dialysis and hemodialysis
- Tube feeding of high-protein formulas/consumption of glucose-rich fluids/parenteral nutrition

Pathogenesis (Fig. 12.12)

- A **partial or relative insulin deficiency** results in **decreased utilization of glucose** by skeletal muscle, fat, and liver, which, in turn, induces hyperglucagonemia and **increases hepatic glucose output**.
- Massive glycosuria results in large amount of water loss which along with decreased intake due to associated illness results in **severe dehydration**. As plasma volume decreases, renal insufficiency develops and limits the renal glucose loss. This increases **further increase in blood glucose levels. Severe hyperosmolality** develops that causes **mental confusion and finally coma**.

Clinical Features

- **Onset:** It is usually more **insidious** in onset compared to DKA. It presents with a several-week history of polyuria, weight loss, and diminished oral intake.
- **Dehydration:** Characteristic clinical features on presentation are **due to volume depletion and extreme dehydration**.



Insulin deficiency
Pancreas
Counterregulatory hormones
↑ Lipolysis
↑ Proteolysis
Gluconeogenic substrates (glycerol, amino acids, and lactate)
↓ Glucose utilization
↑ Gluconeogenesis
↑ Glycogenolysis
Hyperglycemia
Skeletal muscle
Glycosuria (osmotic diuresis)
Loss of water and electrolytes
Dehydration
Decreased fluid intake
Hyperosmolarity
Impaired renal function
Kidneys
HHS

FIG. 12.12: Pathogenesis of hyperosmolar hyperglycemic state (HHS).

- **Central nervous system manifestations:** These include alteration in the level of consciousness ranging from mental confusion, stupor, or coma, **convulsions** (sometimes Jacksonian in type), hemiballism/hemichorea, and transient hemiplegia. Impairment of consciousness is directly related to the degree of hyperosmolality.
- Milder gastrointestinal (GI) symptoms
- Infections, particularly pneumonia or pyelonephritis and gram-negative sepsis are very common.
- Hyperosmolar state may predispose to stroke or myocardial infarction.
- Bleeding and acute pancreatitis may accompany HHS.

Physical examination: Shows severe dehydration, hyperosmolality, hypotension, tachycardia, and altered mental status.

Laboratory Findings

- **Plasma glucose:** Markedly raised and usually **around 1,000 mg/dL** (range 600–2,400 mg/dL)
- **Serum osmolarity:** Usually extremely high

- **Prerenal azotemia** with raised blood urea nitrogen (BUN) and creatinine
- **Plasma bicarbonate:** A mild metabolic acidosis with marginal decrease in plasma bicarbonate (about 20 mmol/L) is seen. Marked decrease in plasma bicarbonate (<10 mmol/L) indicates lactic acidosis.
- **Diagnostic criteria for HHS** (*refer* **Table 12.19**).

Management

- **Fluid replacement:** The average fluid deficit is much higher than DKA and is about 10 L. It should be corrected intravenously. Initially, 2–3 L isotonic (0.9%) saline should be administered over 1–2 hours. Subsequently, half-strength (0.45%) saline should be given. Once the plasma glucose reaches 300 mg/dL, use 5% dextrose-saline solution. Central venous pressure (CVP) should be monitored in patients with cardiac disease.
- **Insulin:** Regular insulin should be administered as low-dose intravenous infusion as in DKA. The goal is to achieve the plasma glucose around 200 mg/dL.
- **Potassium supplementation** is needed early (as in DKA).
- **Lactic acidosis:** Treat with intravenous sodium bicarbonate.
- **Infections:** With suitable antibiotics.
- **Anticoagulants:** To prevent thrombosis.

Q. How will you differentiate between diabetic ketoacidosis (DKA) and hyperosmolar hyperglycemic state (HHS)?

Differentiate between DKA and HHS is described in Table 12.20.

TABLE 12.20: Differentiate between diabetic ketoacidosis and hyperosmolar hyperglycemic state.

Features	*Diabetic ketoacidosis (DKA)*	*Hyperosmolar hyperglycemic state (HHS)*
Clinical features		
Type of diabetes	Both type 1 or type 2 diabetes mellitus (DM)	Type 2 DM
Evolution/onset	Over hours	Over days
Fruity (acetone) odor of breath	Observed	Not present
Kussmaul's respiration	Seen	Not seen
Abdominal pain/ tenderness	Present	Absent
Laboratory findings		
Plasma glucose level	>250 mg/dL	>600 mg/dL
Serum sodium	Normal or low (<140 mmol/L)	Usually high (>155 mmol/L)
Blood/urine ketones	Moderate ketonuria or ketonemia	Absent/Minimal ketonuria and ketonemia
Arterial pH	<7.3	>7.3
Serum bicarbonate	<15 mEq/L	>15 mEq/L
Serum osmolality	Variable	>320 mOsm/L
Anion gap	>12	Variable
Fluid deficit	6 liters	>10 liters
Mortality rate	1%	20–30%

LACTIC ACIDOSIS

This can be a complication of DM, usually seen in critically ill patients, and rarely has been linked to the use of metformin.

Classification of Lactic Acidosis

- **Type A:** Reduced tissue adenosine triphosphate (ATP) (due to reduced tissue perfusion)
- **Type B:** No evidence of reduced perfusion
  - **Type B1:** Systemic disease (diabetes, renal failure, hepatic failure, malignancy)
  - **Type B2:** Drugs (biguanides, alcohol, isoniazid (INH)
  - **Type B3:** Inborn errors of metabolism

Clinical features: Cyanosis, tachycardia, hypotension, cold extremities, altered sensorium, and hyperventilation.

Investigations: High anion gap metabolic acidosis and serum lactate >1 mEq/L.

Treatment: Hydration, intravenous (IV) bicarbonate is the drug of choice, and dialysis can also be done.

HYPOGLYCEMIA

Q. 11.22 Enumerate the causes of hypoglycemia and describe the counter hormone response and the initial approach and treatment.

Whipple's triad: It is the most convincing documentation of hypoglycemia.

- **Symptoms** consistent with **hypoglycemia**
- **Low plasma concentration** of blood glucose ≥70 mg/dL (3.9 mmol/L) measured with a precise method (not a glucose monitor)
- **Relief of symptoms after the plasma glucose level is raised**.

The ADA recommends a plasma glucose threshold of 54 mg/dL for the diagnosis of clinically significant hypoglycemia.

Causes/Etiology (Box 12.15)

Q. Write short essay/note on causes of hypoglycemia.

Significance: Hypoglycemia is a dangerous complication and more serious than hyperglycemia. Prolonged hypoglycemia may cause permanent damage to the brain.

Box 12.15: Causes of hypoglycemia in adults.

- Drugs: Insulin or insulin secretagogues, alcohol, and others
- Critical illness: Hepatic, renal or cardiac failure, sepsis, malaria, and inanition
- Hormone deficiency: Cortisol, glucagon, and epinephrine (in insulin-deficient diabetes)
- Nonislet cell tumor
- Endogenous hyperinsulinism: Insulinoma, functional β-cell disorders (nesidioblastosis), noninsulinoma pancreatogenous hypoglycemia, postgastric bypass hypoglycemia, insulin autoimmune hypoglycemia, antibody to insulin, antibody to insulin receptor, and insulin secretagogue
- Accidental, surreptitious, or malicious hypoglycemia

Pathogenesis

Whenever blood glucose level falls, three primary physiological defense mechanisms come into action:

- **Suppression of endogenous insulin release** from pancreatic β-cells
- **Increased release of glucagon** from pancreatic β-cells
- **Activation of the autonomic nervous system** with release of catecholamines.

In addition, stress hormones, such as cortisol, catecholamines (adrenaline and noradrenaline), and growth hormone (GH), are also increased in the blood.

Mechanism of Hypoglycemia in Diabetes

It may be due to:

- **Insulin excess** (exogenous in patient on insulin therapy)
- **Counterregulatory failure:**
  - In type 1 DM, in the early stages itself, there is loss of capacity to increase glucagon release in response to hypoglycemia.
  - Subsequently, many patients also lose the capacity to release catecholamines in response to hypoglycemia. This is due to diabetic autonomic neuropathy.

Clinical Features

Q. IM11.14 Recognize the presentation of hypoglycemia and outline the principles on its therapy.

- **Blood glucose level and symptom development:** Symptoms due to hypoglycemia usually occur with a plasma glucose at:
  - Level of 60 mg/dL in nondiabetic individuals
  - Higher levels (80 mg/dL) in poorly controlled diabetic patients
  - Lower levels in well-controlled diabetic patients.
- **Symptoms** fall into two main groups:
  - i. **Related to acute activation of the autonomic nervous system (neurogenic symptoms):** These are produced by excessive secretion of adrenaline and symptoms include sweating, tremor, tachycardia, anxiety, and hunger. Adrenergic symptoms predominate when hypoglycemia is of rapid onset (e.g., insulin reactions).
  - ii. Those **secondary to glucose deprivation of the brain (neuroglycopenia):** It causes dizziness, headache, clouding of vision, blunted mental acuity and loss of fine motor skill, confusion, abnormal behavior, convulsions, and loss of consciousness. Central nervous system symptoms predominate when hypoglycemia is of gradual onset. Patients with long-standing diabetes may not develop warning adrenergic symptoms **(hypoglycemic unawareness)** due to severe neuropathy and are at a greater risk of central nervous dysfunction.
- **Daytime versus nocturnal hypoglycemia:**
  - **Daytime hypoglycemic episodes** present with sweating, nervousness, tremor, and hunger.
  - **Nocturnal hypoglycemic episodes** develop during sleep and present with night sweats, unpleasant dreams, and early morning headache. Frequently, nocturnal hypoglycemia is asymptomatic.

Management

- **Oral carbohydrate:** If hypoglycemia is detected early, it may be corrected by ingestion of carbohydrate (preferably in an easily absorbable form).
- **Intravenous dextrose:** It is given in serious hypoglycemia when there is impaired mental functions and prolonged hypoglycemia is anticipated (e.g., with depot insulin and oral sulfonylureas like chlorpropamide). About 100 mL of 25% dextrose is administered. Oral carbohydrate should be given as soon as the patient is able to eat.
- **Glucagon:** Glucagon in the dose of 0.5–1 mg subcutaneously or intramuscularly may be given when there is severe hypoglycemia. It may be repeated if necessary, after 10 minutes. Glucagon stimulates hepatic glycogenolysis, but it may not be effective in severe and prolonged hypoglycemia due to depot insulins. It should not be used for the treatment of hypoglycemia due to oral hypoglycemic drugs.

- **Octreotide:** It is useful for patients who develop recurrent hypoglycemia following dextrose infusion.
- **Other measures** are aimed at preventing recurrence of hypoglycemia. These include adjusting the dose of oral hypoglycemic drugs, changing the timing of insulin injections, adjustments in diet and physical activity/exercise, etc.

Somogyi Phenomenon

Q. Write short note on Somogyi phenomenon.

- The Somogyi phenomenon (posthypoglycemic hyperglycemia) is rebound hyperglycemia that follows an episode of hypoglycemia. It is due to counterregulatory hormone release.
- **Significance:** The correction of the morning hyperglycemia is by reducing and not increasing the evening dose of intermediate-acting insulin.

Clues to the Presence of Somogyi Phenomenon

- **Worsening of diabetic control** in the **presence of increasing insulin doses**. It manifests as morning fasting hyperglycemia in response to unrecognized nocturnal hypoglycemia.
- **Excessive hunger and weight gain** in presence of worsening hyperglycemia.
- **Nocturnal hypoglycemia:** Subtle manifestations such as mild nocturnal sweating, morning headache, and hypothermia.
- **Plasma glucose and urine glucose:** Shows wide fluctuations over short time intervals and not related to meals.
- **Confirmation of Somogyi phenomenon:** By documentation of hypoglycemia at 3 AM and hyperglycemia in the morning (fasting). Improvement in diabetic control after a decrease in the insulin dose.

Dawn Phenomenon

Q. Write short note on Dawn phenomenon.

- It is closely related to the Somogyi phenomenon in that there is fasting hyperglycemia without nocturnal hypoglycemia.
- **Mechanism:** Nocturnal surge of GH release or increased clearance of insulin in the mornings.
- **Confirmation:** Documenting of hyperglycemia at 3 AM and in the morning (fasting).
- **Significance:** Correction of the fasting hyperglycemia depends on increasing and not decreasing the insulin. Differential diagnosis of morning hyperglycemia is mentioned in **Table 12.21**.

TABLE 12.21: Differences in diagnosis of morning hyperglycemia.

Features	*Dawn phenomenon*	*Somogyi effect*
Definition	Recurring early morning hyperglycemia	Early morning hyperglycemia due to treatment with excessive amount of exogenous insulin
Cause	Decrease of insulin secretion between 3 and 5 AM	Nocturnal hypoglycemia due to excessive dose of insulin
Diagnosis (3 AM and 5 AM glucose level)	High/normal plasma glucose level	Low plasma glucose level

Q. List the differences in coma due to hypoglycemia and diabetic coma/ketoacidosis in type 1 diabetes mellitus (DM).

Differences between hypoglycemic and hyperglycemic/diabetic coma are presented in **Table 12.22**. Causes of coma in diabetes are described in **Box 12.16**.

TABLE 12.22: Differences between hypoglycemic and hyperglycemic/diabetic coma.

Features	*Hypoglycemic coma*	*Hyperglycemic coma*
Physical findings		
Volume of pulse	Full	Weak
Respiration	Shallow or normal	Rapid and deep (air hunger)
Blood pressure	Normal/may be raised	Decreased
Skin	Clammy, sweating	Dry
Tongue	Moist	Dry
Tissue turgor	Normal	Reduced
Eyeball tension	Normal	Reduced
Breath acetone	Not present	May be present
Reflexes	Brisk	Diminished
Laboratory findings		
Glucose in urine	Absent/Present (depends on time of last voiding)	Present
Plasma glucose level	Reduced	Raised >200 mg/dL
Plasma acetone	Negative	Usually present
Plasma bicarbonate	Normal	Low <20 mg/L
Plasma carbon dioxide (CO_2)	Normal	Diminished
Blood pH	Normal	<7.35

Q. Write short essay/note on the cause of coma in diabetes.

Box 12.16: Causes of coma in a diabetic patient.

- Diabetic coma:
  - Ketosis producing diabetic ketoacidosis (DKA)
  - Nonketotic hyperglycemic-hyperosmolar coma (NKHHC)
  - Lactic acidosis (LA)
- Hypoglycemic coma (HC)
- Other comorbid conditions: Metabolic encephalopathies or infection related

Chronic Complications of Diabetes

Q. 11.5 Describe and discuss the pathogenesis and temporal evolution of microvascular and macrovascular complications of diabetes.

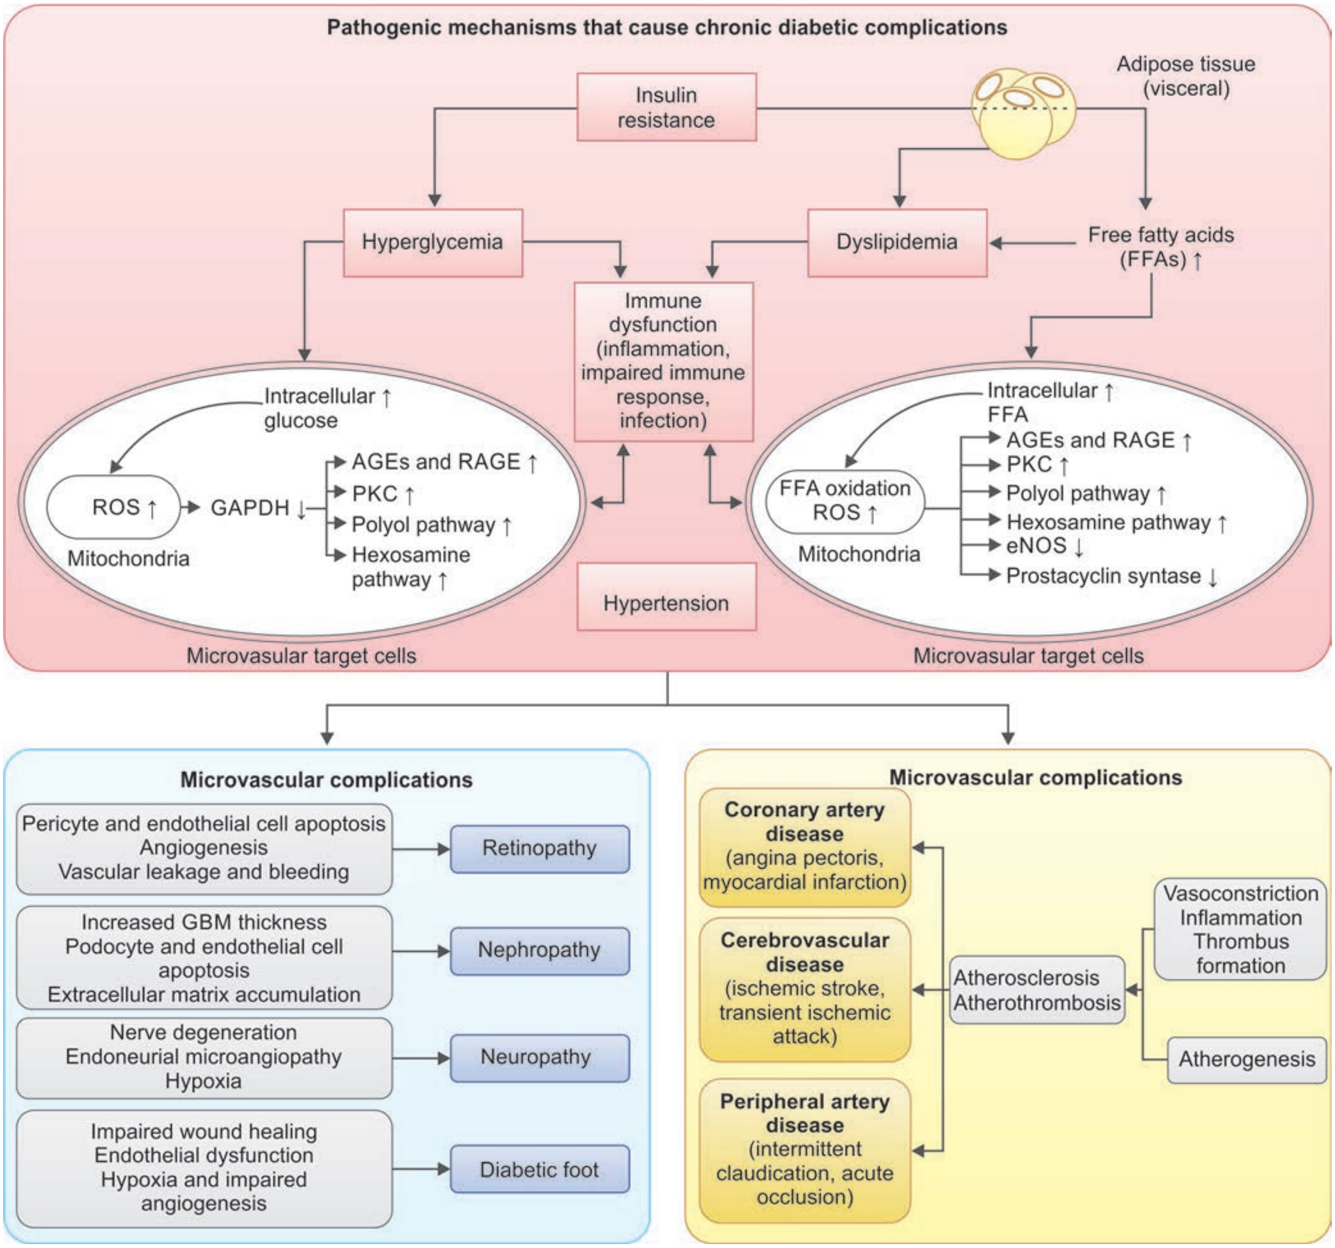
Pathogenesis of chronic complications of diabetes is multifactorial and includes: (1) hyperglycemia (glucotoxicity) is the main mediator, (2) insulin resistance, and (3) obesity.

Hyperglycemia

Effects of hyperglycemia (Fig. 12.13)

These can be brought out by four **distinct metabolic pathways**.

1. **Formation of advanced glycation end products (AGEs):** Increased intracellular glucose leads to **markedly increased** formation of AGEs. AGEs can **directly cross-link extracellular matrix proteins** and its consequences are:



Pathogenic mechanisms that cause chronic diabetic complications
Insulin resistance
Adipose tissue (visceral)
Hyperglycemia
Dyslipidemia
Free fatty acids (FFAs) ↑
Immune dysfunction (inflammation, impaired immune response, infection)
Intracellular ↑ glucose
ROS ↑
GAPDH ↓
AGEs and RAGE ↑
PKC ↑
Polyol pathway ↑
Hexosamine pathway ↑
Mitochondria
Intracellular ↑ FFA
FFA oxidation ROS ↑
AGEs and RAGE ↑
PKC ↑
Polyol pathway ↑
Hexosamine pathway ↑
eNOS ↓
Prostacyclin syntase ↓
Mitochondria
Hypertension
Microvasular target cells
Microvasular target cells
Microvascular complications
Pericyte and endothelial cell apoptosis
Angiogenesis
Vascular leakage and bleeding
Retinopathy
Increased GBM thickness
Podocyte and endothelial cell apoptosis
Extracellular matrix accumulation
Nephropathy
Nerve degeneration
Endoneurial microangiopathy
Hypoxia
Neuropathy
Impaired wound healing
Endothelial dysfunction
Hypoxia and impaired angiogenesis
Diabetic foot
Microvascular complications
Coronary artery disease (angina pectoris, myocardial infarction)
Cerebrovascular disease (ischemic stroke, transient ischemic attack)
Peripheral artery disease (intermittent claudication, acute occlusion)
Atherosclerosis
Atherothrombosis
Vasoconstriction
Inflammation
Thrombus formation
Atherogenesis

FIG. 12.13: Pathogenesis of chronic complications of DM due to hyperglycemia.

(AGEs: advanced glycation end products; DM: diabetes mellitus; eNOS: endothelial nitric oxide synthase; GAPDH: glyceraldehyde-3-phosphate dehydrogenase; GBM: glomerular basement membrane; PKC: protein kinase C; ROS: reactive oxygen species)

- **Basement membrane thickening**
- **Trapping of LDL in the intima accelerating atherogenesis**
- Glomerular dysfunction, endothelial dysfunction, and altered extracellular matrix composition.

2. **Activation of protein kinase C (PKC):** In patients with hyperglycemia, intracellular hyperglycemia stimulates synthesis of diacylglycerol (DAG) from glycolytic intermediates. DAG activates intracellular PKC. PKC activation produces:
   - **Proangiogenic molecules** such as vascular **endothelial growth factor (VEGF)** causes **neovascularization** characteristic of **diabetic retinopathy**.
   - **Profibrogenic factors** [e.g., **transforming growth factor-β (TGF-β)**] results in **increased production of extracellular matrix and basement membrane material**.
   - Plasminogen activator inhibitor-1 (PAI-1) **reduces fibrinolysis and favors vascular occlusion** (by forming atherosclerotic plaques or thrombus).
3. **Disturbances in polyol pathways**: Some tissues (e.g., nerves, lenses, kidneys, and blood vessels) do not require insulin for glucose transport. Persistent hyperglycemia increases the intracellular glucose in these tissues and excess intracellular glucose is metabolized by the enzyme aldose reductase to sorbitol (polyol) to fructose.
   - This **reaction uses NADPH** (the reduced form of nicotinamide dinucleotide phosphate) as a cofactor.
   - NADPH is also necessary for the regeneration of reduced glutathione (GSH). GSH protects against injury by free radicals.
   - Reduced NADPH and decrease in GSH increase cells **susceptibility to oxidative stress**.
4. Hyperglycemia increases the flux through the **hexosamine pathway** and generates fructose-6-phosphate, which results in glycosylation of proteins such as endothelial nitric oxide synthase or by changes in gene expression of TGF-β or PAI-1.

Symptoms of hyperglycemia (Box 12.17)

Box 12.17: Symptoms of hyperglycemia.

- Excessive thirst, dry mouth
- Polyuria, nocturia
- Tiredness, fatigue, lethargy, and weight loss
- Pruritus vulvae/balanitis due to genital candidiasis
- Blurring of vision
- Nausea, headache, mood changes, irritability, difficulty in concentrating, and apathy
- Hyperphagia (especially for sweet foods)

Cardiovascular Complications of Diabetes

Q. Write short essay/note on the cardiovascular complications of diabetes.

The lesions of large- and medium-sized muscular arteries are the **most common causes of mortality** in long-standing diabetes. These include:

Atherosclerosis: Diabetes is one of the major modifiable risk factor for atherosclerosis and other cardiovascular morbidities. The main cardiovascular complications of diabetes are accelerated atherosclerosis.

The **atherosclerosis is more severe and occurs at earlier age**. Diabetics have **increased levels** of **PAI-1**, which **inhibits fibrinolysis and favors development of atherosclerotic plaques**. **Renal arteries** also develop **severe atherosclerosis**. The atherosclerotic lesions can manifest in a variety of ways:

- **Myocardial infarction:** It is due to atherosclerosis of the coronary arteries and is the **most common cause of death in diabetics**. Diabetics have greater risk of coronary artery disease and cardiovascular complications than nondiabetics. Risk for cardiovascular disease is more even in prediabetics.
- **Gangrene of the lower/upper (Fig. 12.14) extremities:** Patient may also present with intermittent claudication. Gangrene may result from advanced vascular disease and is more common in diabetics.
- **Renal vascular insufficiency.**
- **Cerebrovascular accidents** (stroke).

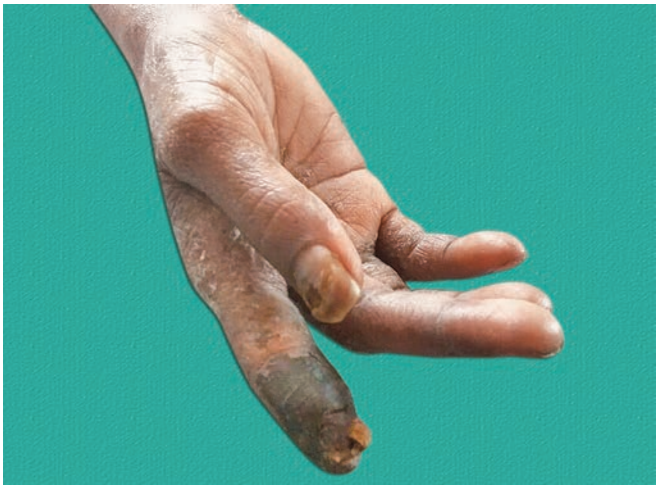


FIG. 12.14: Diabetic gangrene of right index finger.

Diabetic Nephropathy

Q. Write short essay/note on:

- Clinical features, diagnosis, and management of diabetic nephropathy.
- Kimmelstiel–Wilson lesions.

Diabetic nephropathy is the term used for **collective lesions that often occur together in the diabetic kidney**. About **30–40% of all diabetics** develop nephropathy and **are leading cause of chronic kidney disease (CKD) and end-stage renal disease (ESRD)**. It is a leading cause of death and disability in diabetes and is more common in type 1 DM than T2DM. Renal changes in diabetes mellitus are listed in **Box 12.18**.

Pathogenesis

Diabetic glomerulosclerosis represents a part of the generalized diabetic microangiopathy that involves small vessels throughout the body. Like other microvascular complications of DM, the pathogenesis of diabetic nephropathy is related to chronic hyperglycemia.

Box 12.18: Renal changes in diabetes mellitus.

- Glomerular lesions:
  - Diffuse widespread thickening of glomerular basement membrane (GBM)
  - Nodular glomerulosclerosis (Kimmelstiel–Wilson nodules)
  - Insudative lesions: Fibrin caps and capsular drop
- Pyelonephritis: Acute and chronic including necrotizing papillitis
- Tubular lesions: Armanni–Ebstein lesions
- Renal vascular lesions (arteriosclerosis and atherosclerosis)

Clinical Features

The natural history of diabetic nephropathy follows a fairly predictable sequence of events.

- **Glomerular hyperperfusion** and **renal hypertrophy** develop in the first years after the onset of DM. It is associated with an **increase of the glomerular filtration rate (GFR)**. It shows nephromegaly (enlargement of kidneys).
- During the first 5 years of DM, **thickening of the GBM**, glomerular hypertrophy, and expansion of mesangial volume occur as the GFR returns to normal.
- **Microalbuminuria:** After 5–10 years, many patients start excreting **small amounts of albumin in the urine**. It is the **earliest manifestation** of diabetic nephropathy in which the urine has low amounts of albumin (>20 mg/day, but <300 mg/day). Microalbuminuria is defined as the **persistent elevation of the urinary albumin excretion of 20–300 mg/L** (or 20–200 μg/min) in an early morning urine sample. It is also a well-established marker for increased cardiovascular morbidity and mortality in either type 1 or type 2 diabetics. Normal individual excretes albumin <20 mg/day. It indicates early and possibly reversible glomerular damage. Type 2 diabetes is more likely to have microalbuminuria (or overt nephropathy) at diagnosis. This is because of the long duration of abnormal glucose metabolism in T2DM. Hence, patients with T2DM should be screened at the time of diagnosis for the presence of microalbuminuria.
- **Nephropathy with macroalbuminuria:** Without specific interventions, diabetics will develop **overt nephropathy with macroalbuminuria** (>300 mg of urinary albumin per day) usually associated with hypertension. From this stage, the renal disease is irreversible. There is a steady decline in GFR at a rate of about 1 mL/min/month. The stage of macroalbuminuria may progress to nephrotic syndrome.
- **End-stage renal disease:** The overt nephropathy may progress to ESRD. Patient develops azotemia, renal failure, and uremia.

Different stages of diabetic nephropathy are mentioned in **Table 12.23**.

TABLE 12.23: Classification of diabetic nephropathy.

Stages	*Urinary albumin (mg/g Cr) or urinary protein (g/g Cr)*	*GFR [estimated glomerular filtration rate (eGFR)] (mL/min/1.73 m^2)*
Stage 1 (prenephropathy)	Normoalbuminuria (<30)	≥30
Stage 2 (incipient nephropathy)	Microalbuminuria (30–299)	≥30
Stage 3 (overt nephropathy)	Macroalbuminuria (≥300) or persistent proteinuria (>0.5)	≥30
Stage 4 (kidney failure)	Any albuminuria/proteinuria status	<30
Stage 5 (dialysis therapy)	Any status on continued dialysis therapy	

Causes of Microalbuminuria other than Diabetes

Essential hypertension: In hypertensive patients, microalbuminuria **predicts cardiovascular morbidity and mortality**.

Screening for microalbuminuria: It can be done in a variety of ways. Microalbuminuria can be assessed by radioimmunoassay or by using special dipsticks.

- **Measurement of albumin-to-creatinine ratio:** This is most easily obtained with minimal collection errors. A ratio of >30 mg albumin/g creatinine is considered elevated on a spot urine test.
- **Albumin from a 24-hour urine sample:** Urinary albumin >30 mg/24 h is diagnostic.

Management

- **Prevention:** Control of glycemia can reverse microalbuminuria in some patients. Stop smoking and control dyslipidemia.
- **Management of diabetic nephropathy**:
  - Glycemic control: Insulin is the antidiabetic of choice and regular and rapid-acting insulin is preferred.
  - Biguanides are contraindicated if estimated glomerular filtration rate (eGFR) <30 mL/min/1.73 m^2. SGLT2 inhibitors can be used till eGFR >45 mL/min/1.73 m^2. Sulfonylureas, glitazones, and acarbose are avoided.
- **Blood pressure (BP) control:** Recommended BP <140/90 mm Hg. Angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARBs) are first line for BP control.
- **Dietary modification:** Protein restriction, as it reduces hyperfiltration and intraglomerular pressure. Up to 0.8 g/day is recommended by the ADA. Sodium restriction to <2,300 mg/day is also mandated.
- **Miscellaneous:** Treat UTI aggressively. Lipid lowering by HMG-CoA reductase inhibitors.

"Burnt-out" diabetes: Patients with ESRD experience drastic reductions of insulin and OHA requirements due to decreased renal and hepatic insulin clearance, decline in renal gluconeogenesis, deficient catecholamine release, decreased food intake, protein energy wasting, and hypoglycemia due to dialysis.

Ophthalmologic Complications of Diabetes Mellitus

Q. Write short essay/note on ocular complications of diabetes mellitus.

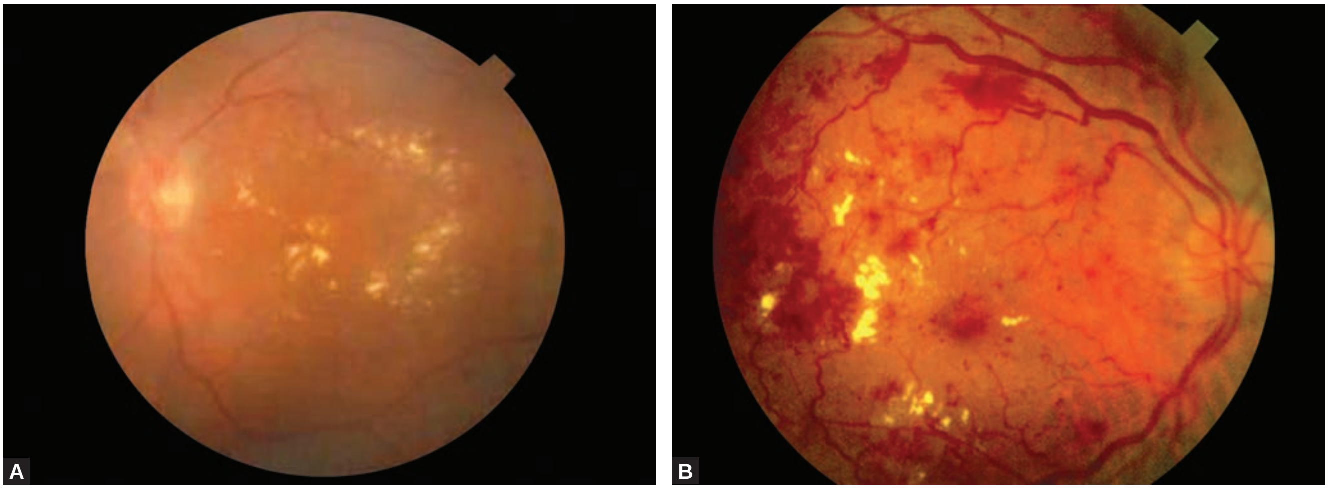
Diabetes can produce different lesions in the eye. These include:

- **Diabetic retinopathy** (DR) (damage to the retina and iris) can lead to blindness.
- **Cataract** is denaturation of the protein and other components of the lens of the eye and leads to opacity of lens. Cataract develops early in diabetics than in the general population. Sustained very poor control of diabetes and ketosis can cause an acute cataract (snowflake cataract). Fluctuations in blood glucose level can cause refractive variability due to osmotic changes within the lens (the absorption of water into the lens can produce temporary hypermetropia). This clinically presents as fluctuating difficulty in reading and it resolves with control of the diabetes.
- **External ocular palsies:** The 6th and the 3rd cranial nerves (**Tolosa–Hunt syndrome**) are the most commonly affected. These nerve palsies usually recover spontaneously within 3–6 months.
- Glaucoma.

Diabetic Retinopathy (Figs. 12.15A and B)

Q. Write short essay/note on diabetic retinopathy.

Diabetic retinopathy is the most commonly diagnosed complication of DM. It is a microangiopathy due to prolonged hyperglycemia causing microaneurysms/hemorrhages/exudates and/or abnormal vessels on the retina. In developed countries, it is one of the most common causes of blindness between 30 and 65 years of age. Its prevalence increases with the duration of diabetes and develops in ~**60–80% of diabetics, about 15–20 years after diagnosis**.



FIGS. 12.15A AND B: (A) Moderate nonproliferative diabetic retinopathy (NPDR) with hard exudates; (B) Proliferative diabetic retinopathy (PDR).

Box 12.19: Risk factors for diabetic retinopathy.

- Long duration of diabetes mellitus
- Poor glycemic control with nephropathy/renal disease
- Hypertension
- Hyperlipidemia
- Pregnancy
- Others: Obesity, smoking

TABLE 12.24: Features of diabetic retinopathy.

Nonproliferative diabetic retinopathy/ simple background (NPDR)	***Proliferative diabetic retinopathy (PDR)***
➢ Develops late in the first decade or early in the second decade ➢ Increased capillary permeability ➢ Marked retinal vascular microaneurysms, capillary closure, and dilatation ➢ Hemorrhages: Dot (capillary microaneurysms) and blot (leakage of blood into deeper retinal layers) ➢ Cotton-wool spots/cytoid bodies (caused by microinfarcts within the retina due to occluded vessels) ➢ Hard exudates (exudation of plasma rich in lipids and protein) ➢ Arteriovenous shunts and dilated veins	➢ New blood vessel formation/ neovascularization ➢ Preretinal or subhyaloid hemorrhage ➢ Vitreous hemorrhage ➢ More numerous microaneurysms and hemorrhages ➢ Changes in caliber of venous vessel ➢ Retinal fibrosis/scar (retinitis proliferans) ➢ Traction retinal detachment

Risk factors for diabetic retinopathy (Box 12.19)

- **Lesions of diabetic retinopathy:** DR can be classified into two stages: (1) nonproliferative/simple background and (2) proliferative (**Table 12.24**).
- **Diabetic macular edema (DME):** In addition to proliferative and nonproliferative DR, patients may also develop clinically significant macular edema (CSME). This can develop at any stage of DR and is characterized by increased vascular permeability and hard exudates in the central retina. CSME is the most common cause of loss of vision in DM.

Investigations

- **Fundus fluorescein angiography (FFA):** In this, a fluorescent dye is injected into a vein of upper arm and photographed in transit through the retinal vessels. It helps to identify the extent of the potentially sight-threatening DR.
- **Optical coherence tomography (OCT):** It is used to image the content of the layers of the retina at the macula and to measure retinal thickness. It helps in detecting macular edema and other macular abnormalities.

Treatment

- **Prevention:** By intensive glycemic, BP **control**, and lipid control in both type 1 or T2DM.
- **Screening:** Regular eye examinations in all patients with DM.
- Diabetic retinopathy is treated by **laser photocoagulation**.
- Proliferative retinopathy is usually treated with **panretinal laser photocoagulation**. **DME** by focal and grid therapy and pars plana vitrectomy is performed for the treatment of nonresolving vitreous hemorrhage and retinal detachment. Intravitreal hyaluronidase, chondroitinase, and plasmin have shown promise in clearing vitreous hemorrhage.
- **Vascular endothelial growth factor inhibitors** such as bevacizumab, ranibizumab, and aflibercept are useful as adjunct therapy to panretinal photocoagulation and/or vitrectomy for selected cases of proliferative diabetic retinopathy (PDR) and DME.

Diabetic Neuropathy

The presence of symptoms and/or signs of peripheral nerve dysfunction in people with diabetes after the exclusion of other causes.

Q. Write short essay/note on:

- Different neurological complications/manifestations of diabetes mellitus.
- Classification, clinical manifestations, and management of diabetic neuropathy.

Diabetes can involve the **peripheral nervous systems** in a number of ways.

Risk factors: Similar to other complications of DM, the development of neuropathy is related to the duration of diabetes and the degree of glycemic control. Other risk factors are greater BMI and smoking.

Classification of diabetic neuropathy: There are various classifications of diabetic neuropathy and one of them is presented in **Box 12.20**.

Box 12.20: Classification of diabetic neuropathy.

- **Diffuse neuropathy:**
  Distal symmetrical polyneuropathy (DSPN):
  - Small fiber
  - Large fiber
  - Mixed (most common)
- **Mononeuropathy (mononeuritis multiplex):**
  - Isolated cranial/peripheral nerve
  - Mononeuritis multiplex
- **Radiculopathy or polyradiculopathy:**
  - Radiculoplexus neuropathy
  - Thoracic radiculopathy
- **Nondiabetic neuropathies common in diabetes:**
  - Pressure palsies
  - Chronic inflammatory demyelinating polyneuropathy (CIDP)
  - Treatment-induced painful small fiber neuropathy

Polyneuropathy

Distal symmetric sensorimotor polyneuropathy

- It is the most common form of diabetic neuropathy. It affects both **motor and sensory function** of the lower extremities. It can be divided into two types:
    1. **Asymptomatic**: It is a relatively asymptomatic form. It is diffuse, distal, usually involves the lower extremities, and later it may involve the upper extremities with a "**glove and stocking**" type of distribution.
    2. **Acute** painful **neuropathy**: It is a diffuse, painful neuropathy, and is less common. It presents with burning or crawling or dull aching sensation or excruciating, lancinating pain in the feet, shins, and anterior thighs. The pain is typically worse at night and pressure from bedclothes may be intolerable and partially relieved by movement. Hyperesthesia may be severe.

In both forms, physical findings are: Loss of vibration sense, loss of tendon reflexes in the lower limbs (especially ankle jerk), and "glove and stocking" impairment of all sensation.

- With progression, patients may complain of a feeling of "walking on cotton wool" and loss of balance while washing the face ("wash-basin sign") or walking in the dark owing to impaired proprioception. It may be associated with involvement of other sensation such as joint position, touch, pain, and temperature, later leading to weakness and wasting of muscles.
- **Sequelae of neuropathy:** Involvement of motor nerves to the small muscles of the feet results in interosseous wasting. Unbalanced traction by the long flexor muscles results in a characteristic shape of the foot with a high arch and clawing of the toes. This can lead to abnormal distribution of pressure on walking, producing callus formation under the first metatarsal head or on the tips of the toes. Complications include unrecognized trauma, beginning as blistering due to an ill-fitting shoe, and neuropathic ulceration. Sometimes, **neuropathic arthropathy (Charcot's joints)** may develop in the ankle.

Asymmetrical motor diabetic neuropathy (Diabetic amyotrophy/Bruns–Garland syndrome)

Q. Write short essay/note on diabetic amyotrophy.

- Usually develops in older individuals with diabetes.
- It presents with asymmetrical, severe, and progressive weakness and atrophy of the proximal (quadriceps) muscles of the lower limbs. It is associated with severe pain, mainly on the anterior aspect of the leg, and hyperesthesia and paresthesias.
- Sometimes, there may be marked wasting and weight loss ("neuropathic cachexia"). The patient may appear extremely ill and be unable to get out of bed. Tendon reflexes may be diminished or absent on the affected side(s).
- This neuropathy is probably due to the acute infarction of the lower motor neurons of the lumbosacral plexus. Other lesions of this plexus (e.g., neoplasms and lumbar disc disease) must be excluded, before a diagnosis is made.
- It is seen in patients with poor glycemic control and resolves with optimization of metabolic control.
- Management is mainly supportive.

Mononeuropathy and Mononeuritis Multiplex

Mononeuropathy characterized by dysfunction of isolated cranial or peripheral nerves is less common than polyneuropathy in DM.

- **Nerve involvement:** Diabetic mononeuropathy can involve a single **peripheral or cranial nerve** and affect either motor or sensory function. Usually, it affects 3rd, 6th, 4th (Tolosa–Hunt) or 7th (Bell's palsy) cranial nerves and the **femoral and sciatic nerves** (in order of frequency). Third nerve involvement is characterized by diplopia and normal pupillary constriction to light (pupil sparing). Rarely, other single nerves are involved and produce paresis and paresthesias in the thorax and trunk (truncal radiculopathies). Simultaneous involvement of more than one nerve (mononeuropathy multiplex) may also occur.
- **Presentation:** Unlike the gradual progression of distal symmetrical and autonomic neuropathies, the mononeuropathies present as **rapid, severe pain and motor weakness** in the distribution of a single nerve. However, eventually they recover.
- **Nerve compression palsies:** Mononeuropathies can present with or without nerve compression. Nerve compression is more common in diabetes. Compression may affect the median nerve (presents the clinical picture of **carpal tunnel syndrome**), lateral popliteal nerve (**foot drop**), or less commonly the ulnar nerve (**wrist drop**). Compression palsies may be due to glycosylation and thickening of connective tissue and/or increased susceptibility of nerves affected by diabetic microangiopathy.

Autonomic Neuropathy (Table 12.25)

- Autonomic neuropathy may affect both the sympathetic and parasympathetic nervous systems.
- Diabetes mellitus-related autonomic neuropathy can involve one or more systems, including the cardiovascular, GI, genitourinary, sudomotor, and metabolic systems **(Table 12.25)**.
- It may result in loss of awareness of hypoglycemia and can cause disabling postural hypotension.

TABLE 12.25: Clinical features of diabetic autonomic neuropathy.

System involved	*Clinical features*
Cardiovascular	Postural hypotension, resting tachycardia, fixed heart rate, impaired Valsalva maneuver, painless myocardial infarction, and sudden cardiac death
Gastrointestinal	Dysphagia (due to esophageal atony), abdominal fullness, nausea, vomiting, gastroparesis, nocturnal diarrhea, constipation, and fecal incontinence
Genitourinary	Difficulty in micturition, urinary incontinence, recurrent infection, impotence, erectile dysfunction, and retrograde ejaculation
Sudomotor	Gustatory sweating, nocturnal sweat without hypoglycemia, fissures in feet, and anhidrosis
Vasomotor	Feet feel cold (due to loss of skin vasomotor responses), dependent pedal edema (due to loss of vasomotor tone and increased vascular permeability)
Pupillary	Decreased pupil size, delayed or absent reflexes to light, resistance to mydriatics, and Argyll–Robertson pupil
Metabolic	Hypoglycemia unawareness

Management

Strict glycemic control, foot care

- **Mononeuropathies are usually self-limiting** and do not require any specific therapy. Explanation and reassurance about remission within months may be necessary.
- **Neuritic pain** of diabetic neuropathy may be treated with nonsteroidal anti-inflammatory drugs (opiates—tramadol, oxycodone), tricyclic antidepressants (amitriptyline, imipramine, duloxetine, venlafaxine mexiletine, valproate), and anticonvulsants (e.g., phenytoin, carbamazepine, gabapentin, or pregabalin). Duloxetine is an antidepressant, potent dual reuptake inhibitor of serotonin and noradrenaline is useful in refractory cases.
- Transepidermal nerve stimulation (**TENS**): Beneficial in some patients.
- Topical **capsaicin**-containing creams: May be occasionally beneficial.
- **Orthostatic/postural hypotension:** Responds to sleeping with the head of the bed raised, avoiding sudden upright position, full-length elastic support stockings, and increased salt intake. Rarely, fludrocortisone and α-adrenoceptor agonist (midodrine) are needed.
- **Gastroparesis:** Patient is advised to take frequent small meals and prokinetic agents. Dopamine antagonists (metoclopramide, domperidone), erythromycin, and gastric pacemaker; percutaneous enteral (jejunal) feeding may be necessary in some cases.
- **Diarrhea:** In diabetics, it often responds to diphenoxylate, loperamide, or broad-spectrum antibiotics (e.g., tetracyclines). Rarely, clonidine and octreotide may be needed.
- **Constipation:** It can be treated by stimulant laxatives (Senna).
- **Atonic bladder:** By intermittent self-catheterization.
- **Excessive sweating:** By anticholinergic drugs (propantheline, poldine, oxybutynin), clonidine, or topical antimuscarinic agent (glycopyrrolate cream).
- **Erectile dysfunction:** Treatment includes:
  - Psychological counseling; psychosexual therapy
  - Phosphodiesterase type 5 inhibitors: Oral therapy with sildenafil, vardenafil, and tadalafil
  - Dopamine agonist (apomorphine) through sublingual route
  - Prostaglandin E (alprostadil): Injected into corpus cavernosum or intraurethral administration of pellets
  - Vacuum tumescence devices
  - Implanted penile prosthesis.

Specific treatment to reverse neuropathy

- **α-lipoic acid:** It is a natural cofactor of dehydrogenase complex and is an antioxidant (redox-modulating agent). It may ameliorate both somatic and autonomic diabetic neuropathies.
- **Aldolase reductase inhibitors (e.g., epalrestat):** They decrease the flux of glucose through polyol pathways, inhibit accumulation of sorbitol and fructose, and prevent reduction of redox potential. However, they are not effective.
- **Carnitine** may be useful in few cases.
- **Methylcobalamin** may provide some benefit.
- **Ruboxistaurin, a PKC-β inhibitor, is** an emerging treatment for diabetes microvascular complications.

Dermatological Complications of Diabetes Mellitus (Box 12.21)

Q. R18.1 **Write short note on dermatological/cutaneous complications of diabetes mellitus.**

Musculoskeletal Complications of Diabetes Mellitus (Box 12.22)

Q. Write short note on musculoskeletal complications of diabetes mellitus.

Box 12.21: Dermatological complications of diabetes mellitus (DM).

- Skin infections: Due to immune dysfunction, e.g., carbuncles and furuncles and intertrigo (**Fig. 12.16**)
- Balanoposthitis (**Fig. 12.17**)
- Vaginal candidiasis/balanitis (**Fig. 12.18**): Due to immune dysfunction
- Diabetic ulcers: Due to peripheral neuropathy and ischemia
- Xanthomatoses: Due to hyperlipoproteinemia
- Necrobiosis lipoidica diabeticorum (NLD)
- Diabetic dermopathy (shin spots)
- Tight waxy skin and the dorsum of the hands with joint contractures in type 1 DM—digital sclerosis
- Acanthosis nigricans
- Acrochordons/skin tags: Marker of insulin resistance
- Granuloma annulare
- Diabetic blisters: Bullosis diabeticorum

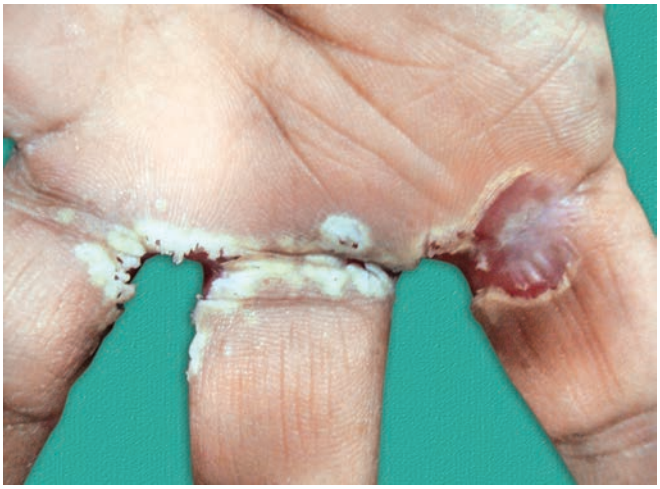


FIG. 12.16: Intertrigo (intertriginous dermatitis) characterized by inflammation of skinfolds.

GESTATIONAL DIABETES MELLITUS

Q. Write short essay/note on gestational diabetes mellitus (GDM), its significance, and management.

Gestational diabetes mellitus (GDM) is defined as **glucose intolerance (diabetes) that develops or is first recognized during pregnancy**. Typically, it is asymptomatic and usually remits after delivery. However, there is an increased risk of type 2 diabetes in later life and maintaining a low body weight and keeping physically active can reduce this risk.

Risk factors for GDM, low-risk groups for GDM, and importance of diagnosis of GDM are mentioned in **Boxes 12.23 to 12.25**, respectively.

Box 12.22: Musculoskeletal complications in diabetes.

- Diabetic muscle infarction: Painful muscle swelling, usually in thigh
- Neuropathic arthropathy (Charcot joint)
- Carpal tunnel syndrome
- Dupuytren's contracture
- Flexor tenosynovitis
- Adhesive capsulitis (frozen shoulder)
- Diabetic cheiroarthropathy—"prayer sign" and "tabletop test"
- Diabetic sclerodactyly

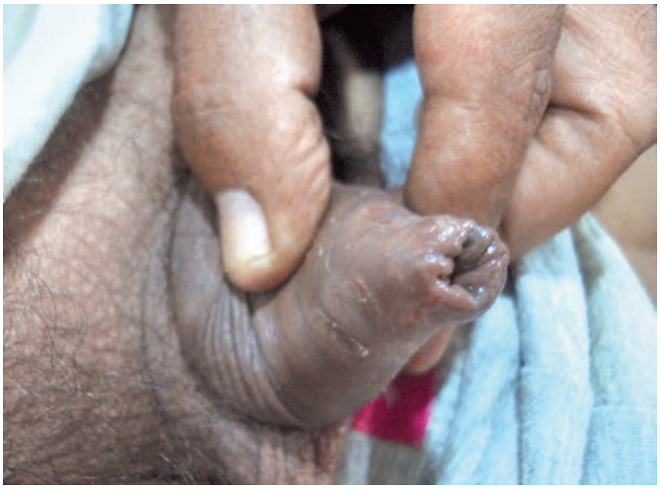

FIG. 12.17: Balanoposthitis.

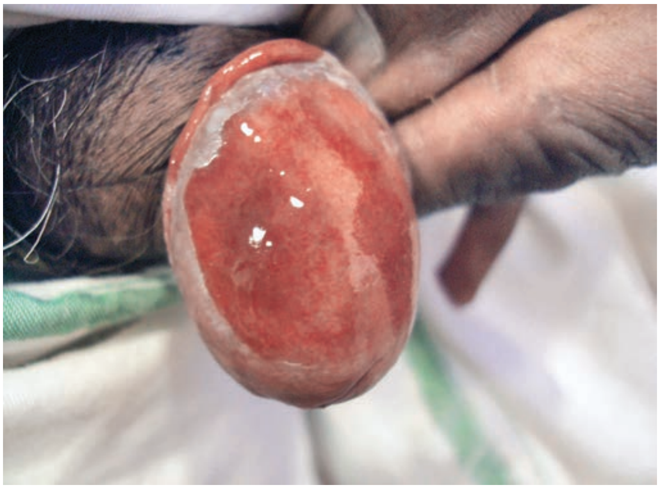

FIG. 12.18: Candida balanitis.

Box 12.23: Risk factors that predispose to gestational diabetes mellitus.

Women with:

- Previous history of gestational diabetes
- Obesity (overweight) and pregnancy at older age
- History of large for gestational age babies
- Ethnic groups at particular risk

Box 12.24: Low-risk groups for gestational diabetes mellitus.

Women with:

- Age below 25 years
- Normal weight before pregnancy
- Member of an ethnic group with a low prevalence of diabetes
- No diabetes in first-degree relatives
- No history of abnormal glucose tolerance or poor obstetrical outcome

Oral Glucose Tolerance Test

- Diagnosis is based on an OGTT performed at 24–28 weeks of gestation in women with moderate-to-high risk.
- **Method:** 100 g glucose is dissolved in 300–400 mL of water and consumed over 5 minutes. The quantity of glucose is more than usual glucose load of 75 g and is recommended because there is an increased turnover of glucose in pregnancy.

Criteria for Diagnosis of Gestational Diabetes Mellitus (Table 12.26)

TABLE 12.26: Criteria for diagnosis of gestational diabetes mellitus.

Time (hour)	*Upper limit of normal values (mg/dL)*	
	Whole blood (O'Sullivan)	*Plasma (Carpenter and Coustan)*
0 (fasting)	85	95
1	160	180
2	140	155
3	125	140

(Two or more of these values must be abnormal).

Box 12.25: Importance of diagnosis of gestational diabetes mellitus (GDM).

Fetal risk with GDM:

- Fetal macrosomia
- Intrauterine fetal death
- Respiratory distress
- Hypoglycemic fetuses
- Polyhydramnios
- Hypocalcemia
- Increased incidence of shoulder dystocia
- Fetal hyperbilirubinemia
- Transient tachypnea of the newborn

Risk for offspring of women with GDM: Increased risk of obesity and diabetes

Risk for women with GDM: Increased risk of obesity and diabetes in future.

- Increased incidence of preeclampsia
- Cesarean section

Management

Aim

To normalize the maternal blood glucose and reduce excessive growth of fetus.

- **Insulin**: Initiate insulin therapy when target glucose levels exceed despite nutritional therapy. Insulin does not cross the placenta.
- **Dietary modification**: Reduce the consumption of quick-acting refined carbohydrate. Treatment for other patients with diet in the first instance, although most may require insulin at some stages during pregnancy.
- Many oral hypoglycemic drugs cross the placenta and should be avoided because of the potential risk to the fetus. However, *metformin or glyburide/glibenclamide* is considered safe to use in pregnancy.

Follow-up

Though the sugar levels normalize after delivery, it is advised to repeat an OGTT 6 weeks postpartum.

METABOLIC SYNDROME

Q. Write short essay or note on:

- **Metabolic syndrome/insulin resistance syndrome and its components.**
- **Clinical diagnosis, risks, and treatment of insulin resistance syndrome (syndrome X).**

Metabolic syndrome (also known as the *insulin resistance syndrome, Reaven syndrome, dysmetabolic syndrome*, and *syndrome X* syndrome) is a proinflammatory, prothrombotic state that consists of a **cluster of clinical findings and laboratory abnormalities**.

- **Clinical findings:** Include obesity (central, abdominal, or visceral), increased sympathetic nervous system activity, and hypertension. Risk factors associated with metabolic syndrome are listed in **Table 12.27**. These clinical features include acanthosis nigricans, skin tags—acrochordons, ovarian hyperandrogenism [polycystic ovary syndrome (PCOS)], and lipodystrophy.
- **Laboratory abnormalities**: Cardiovascular risk factors and it includes hyperglycemia, dyslipidemia (high TGs, low HDL), glucose intolerance, insulin resistance (the common etiologic factor), and hyperinsulinemia (compensatory).
- **Pathogenesis:** The basic defect is insulin resistance.
    - Insulin resistance is **the decrease/failure of target (peripheral) tissues to insulin action**. Insulin is unable to produce its numerous actions in spite of unimpaired secretion from the P-cells.

TABLE 12.27: Risks associated with metabolic syndrome.

- Cardiovascular diseases (atherosclerotic vascular disease, specifically coronary artery disease)
- Type 2 diabetes mellitus
- Nonalcoholic fatty liver disease
- Sleep disorders: Obstructive sleep apnea
- Polycystic ovary syndrome (PCOS)
- Hyperuricemia
- Chronic kidney disease
- Erectile dysfunctions

  - **Main factors** in the development of insulin resistance are combination of genetic susceptibility and obesity. The **obesity** accompanying T2DM is central obesity and central adipose tissue is more "lipolytic" than peripheral sites. Insulin resistance is induced by FFAs, adipokines, and chronic inflammation in adipose tissue.
  - **Consequences of insulin resistance:**
    - **Decreased uptake of glucose in muscle** results in postprandial hyperglycemia. The defects in the uptake are due to defect in the receptors present in target tissues and usually at the postreceptor level.
    - **Reduced glycolysis** and **fatty acid oxidation** in the liver.
    - **Inability to suppress hepatic gluconeogenesis.**
- **Clinical diagnosis (Box 12.26):** Individual on medical treatment for dyslipidemia or hypertension and those with isolated systolic or diastolic hypertension are included in the above criteria.

Box 12.26: Diagnostic criteria for metabolic syndrome.

Presence of at least three of the following:
- Abdominal obesity (waist circumference ≥88 cm in women and ≥102 cm in men
  - **Body mass index ≥30 kg/m^2 and/or waist-hip ratio ≥0.9 in men and ≥0.85 in women**
- Raised triglyceride (TG) levels (≥150 mg/dL) or on treatment for TG
- Reduced high-density lipoproteins (HDLs) cholesterol level (<40 mg/dL in males and <50 mg/dL in females) or on treatment for HDL
- Raised blood pressure (systolic ≥130 mm Hg or diastolic ≥85 mm Hg)
- Raised fasting glucose level (110–125 mg/dL); type 2 diabetes mellitus (DM) or impaired glucose tolerance and/or insulin resistance denoted by hyperinsulinemia relative to glucose levels

Management

Currently, there is no evidence that treatment of insulin resistance reduces mortality and morbidity in metabolic syndrome. However, treatment of insulin resistance consists of:
- Lifestyle changes and exercise
- Diet: Low in calories and high in fibers
- Reduction of weight
- Treatment and control of diabetes, hypertension, and lipid abnormalities.

CHAPTER 13

Endocrinology

DISORDERS OF PITUITARY AND HYPOTHALAMUS

Pituitary Hormones and their Principal Actions (Table 13.1)

Q. Write short essay/note on:

- Pituitary hormones and their principal actions.
- List the hormones of anterior pituitary.

TABLE 13.1: Pituitary hormones and principal actions.

Hormone	*Actions*	
	Anterior Pituitary Hormones	
Thyroid-stimulating hormone (TSH)	Synthesis and secretion of thyroxine (T_4) and tri-iodothyronine (T_3)	
Growth hormone (GH)	Growth induction	
Follicle-stimulating hormone (FSH) **Luteinizing hormone (LH)**	Sex-steroid production, follicle growth, germ-cell maturation	
	Males: ➢ FSH and LH: Spermatogenesis ➢ FSH: Stimulates Sertoli cells to secrete androgen binding protein (ABP), transferrin, plasminogen activator, and inhibin ➢ LH: Stimulates Leydig cells to produce testosterone	**Females:** ➢ FSH and LH are necessary for the development of corpus luteum during the luteal phase of menstrual cycle ➢ FSH promotes growth and development of ovarian follicles during the follicular phase of menstrual cycle ➢ LH (LH surge) induces ovulation
Prolactin (PRL)	Controls milk production by breasts	
Adrenocorticotrophic hormone (ACTH)	Controls cortisol release from adrenal cortex and skin pigmentation	
	Posterior Pituitary Hormones	
Arginine vasopressin (AVP)/ADH	Promotes reabsorption of water by distal convoluted tubule (DCT) and collecting tubules	
Oxytocin	Promotes uterine contraction and expression of milk from the breasts	

Hypopituitarism

Q. Write short essay/note on hyposecretion of anterior pituitary hormones/hypopituitarism/panhypopituitarism.

Definition

- Hypopituitarism is defined as **combined deficiency (partial or complete) of any of the anterior pituitary hormones**.
- Panhypopituitarism is defined as **deficiency of all anterior pituitary hormones**. It may be due to selective or multiple deficiencies of pituitary hormones or diseases of the hypothalamus.

Etiology

See **Box 13.1**.

Box 13.1: Various causes of hypopituitarism.

"Nine **I**'s": **Invasive, Infarction, Infiltrative, Injury, Immunologic, Iatrogenic, Infectious, Idiopathic, and Isolated.**

- **Isolated** hormone **deficiencies**
- **Invasive tumors:** Pituitary adenomas, cysts, metastasis, and hypothalamic tumors
- **Injury:** Surgery, irradiation, and stalk section
- **Infarction:** Sheehan's syndrome (postpartum pituitary necrosis), diabetic antepartum necrosis, and carotid aneurysm
  - **Cerebrovascular accident (CVA):** Ischemic stroke, subarachnoid hemorrhage, and pituitary apoplexy
- **Inflammatory diseases:** Granulomatous disease and autoimmune (lymphocytic) hypophysitis
- **Infiltrative diseases:** Hemochromatosis, amyloidosis, sarcoidosis, Langerhans' cell histiocytosis
- **Injury:** Head trauma
- **Immunologic:** Lymphocytic hypophysitis
- **Infections:** Meningitis, tuberculosis, syphilis, fungal infection such as *Candida* and Hantavirus. More likely immunocompromised patients such as HIV and high-dose steroids
- **Idiopathic**
- **Pituitary stalk interruption syndrome**
- **Empty sella syndrome (ESS)**
- **Developmental defects** (Kallmann syndrome) and **genetic diseases** such with mutations detected in:
  - ROBOS guidance receptors (ROBOS) determine axonal guidance in the central nervous system.
  - BMP4 induces Rathke's pouch formation, which is necessary for anterior pituitary development.
  - *HESX1*, *LHX3*, and *LHX4* transcription factors that are important for pituitary organogenesis and early differentiation of pituicytes.
  - PROP-1, which is necessary for the differentiation of a cell type that is a precursor to somatotroph, lactotroph, thyrotroph, and gonadotroph cells.
  - PIT-1 (called POU1F1 in the human), which acts temporally just after PROP-1 and is necessary for the differentiation of a cell type that is a precursor of somatotroph, lactotroph, and, to a lesser degree, thyrotroph cells.
  - TPIT, which is required for specific differentiation of the corticotroph cells.

Clinical Features (Table 13.2)

- The presentation is highly variable and depends on the underlying cause/lesion.
- Symptoms and signs depend on the degree of hypothalamic and/or pituitary deficiencies. Mild deficiencies may be asymptomatic.
- **Hypopituitarism secondary to pituitary tumors:** Symptoms are due to mass effects (e.g., headache, visual impairment, electrolyte alterations, and disorders of the autonomic nervous system produced by hypothalamic involvement). As the lesions progress, there is a sequential loss of hormone secretion.
- Prolactin (PRL) deficiency is rare, except for complete destruction of pituitary or genetic syndromes.
- The order of diminished trophic hormone reserve function by pituitary compression usually follows the order **GH > FSH > LH > TSH > ACTH.**
- Longstanding panhypopituitarism produces a classic picture of **pallor with hairlessness ("alabaster skin").**

TABLE 13.2: Clinical features due to deficiencies of various pituitary hormones.

Deficiency	*Features*
GH ***(earliest to be lost)***	➢ Decreased growth in children but may be clinically occult in adult patients ➢ Associated with a decreased sense of well-being, lethargy, muscle weakness, and increased fat mass with a decrease in lean body mass
LH and FSH	➢ Hypogonadism may precede the clinical appearance of a hypothalamic-pituitary lesion ➢ Leads to loss of libido and impotence in males, and oligomenorrhea or amenorrhea in females ➢ In both sexes, infertility and osteoporosis occur, axillary and pubic hair becomes sparse, and the skin becomes fine and wrinkled ➢ In males, there may be gynecomastia and decreased frequency of shaving
ACTH	➢ Weakness, nausea, vomiting, anorexia, decreased libido, weight loss, fever, tachycardia, and postural hypotension may occur. Severe forms of deficiency cause death due to vascular collapse. Plasma electrolytes are normal (relative preservation of mineralocorticoid production) ➢ Depigmentation and diminished tanning may develop due to ACTH insufficiency
TSH	Secondary hypothyroidism is usually less severe than primary hypothyroidism, and goiter is absent. Cold intolerance, dry skin, mental dullness, bradycardia, delayed relaxation phase of the deep tendon reflexes, constipation, weight gain, hoarseness, and anemia are seen
PRL	Failure of lactation (postpartum)

(ACTH: Adrenocorticotropic hormone; FSH: Follicle-stimulating hormone; GH: Growth hormone; LH: Luteinizing hormone; PRL: Prolactin; TSH: Thyroid-stimulating hormone)

Laboratory Investigations

- **Indications for testing**: Pituitary function should be tested when a patient is found to have a disease that affects the hypothalamus or pituitary or any feature of endocrine deficiency of central origin.
- **ACTH**: Corticotropin (ACTH) secretion is tested by measuring serum cortisol at 8 AM on 2 or more occasions; if the value is <3 μg/dL, cortisol deficiency is diagnosed, and if >18 μg/dL, the patient has cortisol sufficiency. If the value is persistently intermediate, a test of ACTH reserve, such as a **metyrapone test** or **cosyntropin stimulation test**, should be performed.
- **Metyrapone test**: Metyrapone blocks 11-beta-hydroxylase, the enzyme that catalyzes the conversion of 11-deoxycortisol to cortisol, resulting in a reduction in cortisol secretion. If the HPA axis is normal, the ensuing fall in serum cortisol should cause an increase in ACTH secretion and therefore an increase in adrenal steroidogenesis and 11-deoxycortisol.

  In normal subjects, administration of 750 mg of metyrapone orally every 4 hours for 24 hours results in a decline in 8 AM serum cortisol to <7 μg/dL and an elevation in 8 AM serum 11-deoxycortisol to ≥10 μg/dL at the end of the 24 hours. In patients who have decreased ACTH reserve due to hypothalamic or pituitary disease, the serum 11-deoxycortisol concentration will be <10 μg/dL and the serum cortisol <7 μg/dL at the end of 24 hours.
- **TSH**: To evaluate thyrotropin (TSH) secretion, measure free T_4 (FT_4) or total thyroxine (T_4) and triiodothyronine (T_3) uptake. The serum TSH should not be used to make the diagnosis, because it is usually within the normal range, although sometimes low or even slightly high.
- **Gonadotropins**: Gonadotropin secretion in males is tested by measuring the serum total testosterone concentration on 2 or more occasions at 8 AM. A low testosterone, assuming he is not obese (or free testosterone if he is obese), and luteinizing hormone (LH) that is not elevated indicate secondary hypogonadism. Gonadotropin secretion in females of premenopausal age who has amenorrhea is tested by measuring estradiol. A low estradiol and follicle-stimulating hormone (FSH) that is not elevated indicate secondary hypogonadism.
- **GH**: Growth hormone secretion can be assumed to be subnormal if the patient has organic pituitary disease; deficiencies of ACTH, TSH, and gonadotropins; and either an age-specific low serum insulin-like growth factor-1 (IGF-1) concentration or a subnormal growth hormone response to a test of growth hormone stimulation.
- **Demonstration of low levels of trophic pituitary hormones:** Biochemical diagnosis of pituitary insufficiency is made by demonstration of low levels of trophic pituitary hormones along with low levels of target hormones.
  - **Low free thyroxine (T_4)** with **low or inappropriately normal TSH** level suggests **secondary hypothyroidism**.
  - **Low early morning (8-9 AM) cortisol,** about ≤3 μg/dL, with **low or inappropriately normal ACTH.**
  - **Low testosterone level without elevation of gonadotrophins** (LH and FSH) suggests **hypogonadotropic hypogonadism.**
  - **Low IGF-1 (insulin-like growth factor-1)** level indicates **GH deficiency.**
- **Provocation tests: These may be necessary to assess pituitary reserve.**
  - **GH reserve:** GH response to insulin-induced hypoglycemia, L-dopa, arginine, growth hormone-releasing hormone (GHRH) or growth hormone-releasing peptides (GHRPs). Insulin-induced hypoglycemia (also known as **insulin tolerance test**) is the **gold standard test**.
  - **Thyrotropin-releasing hormone (TRH) reserve: TRH** stimulates **prolactin secretion**. In the presence of optimal levels of TRH, exogenous administration of TRH will not raise levels of prolactin. In the absence of a TRH reserve, exogenous administration of TRH will elevate serum prolactin levels.
  - **ACTH reserve:** It is assessed by measuring ACTH and cortisol levels during insulin-induced hypoglycemia. Corticotropin-releasing hormone (CRH) administration induces ACTH release, and administration of synthetic ACTH (cosyntropin) causes adrenal cortisol release. It is an **indirect indicator** of **pituitary ACTH reserve**.
  - **Metyrapone test:** Metyrapone **blocks 11-beta-hydroxylase**, the enzyme that catalyzes the conversion of 11-deoxycortisol to cortisol, resulting in a reduction in cortisol secretion. If the hypothalamo-pituitary-adrenal axis is normal, the ensuing fall in serum cortisol should cause an increase in ACTH secretion and therefore an increase in adrenal steroidogenesis and 11-deoxycortisol.

    In normal subjects, administration of 750 mg of metyrapone orally every 4 hours for 24 hours results in a decline in 8 AM serum cortisol to <7 μg/dL and an elevation in 8 AM serum 11-deoxycortisol to ≥10 μg/dL at the end of the 24 hours. In patients who have decreased ACTH reserve due to hypothalamic or pituitary disease, the serum 11-deoxycortisol concentration will be <10 μg/dL and the serum cortisol <7 μg/dL at the end of 24 hours.
  - **TSH reserve:** TSH response to TRH.
- **Surgical biopsy of tumor:** Usually done as part of a therapeutic operation of tumors. Histological examination of pituitary tumors will help in **identifying the type of tumor**. Immunohistochemistry useful in confirming their secretory capacity.

- **Chromophobe** (usually nonfunctioning)
- **Acidophil** (typically prolactin- or growth-hormone secreting)
- **Basophil** (typically ACTH-secreting).

Management: It is by replacement of deficient hormones **(Box 13.2)**.

Sheehan's Syndrome

Q. Write a short note on Sheehan's syndrome.

Sheehan's syndrome is a potentially life-threatening complication due to **infarction of pituitary gland following postpartum hemorrhage**.

Mechanism

During pregnancy, the pituitary gland is enlarged and is more vulnerable to ischemia. Postpartum hemorrhage and consequent systemic hypotension can cause pituitary infarction.

Clinical Features

- Earliest symptom is **failure to lactate**.
- **Failure to regain menstruation after delivery**.
- **Other symptoms of hypopituitarism:** They appear over months or years. Few patients may present acutely (hypotension, hyponatremia, and hypothyroidism).
- Coma and death can occur in severe cases.

Diagnosis

- *Refer* laboratory findings of hypopituitarism.
- **MRI:** In early stages, it may show hypertrophied pituitary. Later stages, atrophic pituitary and empty sella.

Box 13.2: Replacement therapy for adult hypopituitarism.

Adrenocorticotropic hormone

Hydrocortisone 15–25 mg daily in divided doses. Mineralocorticoid replacement not needed.

Follicle-stimulating hormone/luteinizing hormone

Female Patients (any one)

- Conjugated estrogen 0.65 mg/day
- Micronized estradiol 1 mg/day
- Ethinyl estradiol 0.02–0.05 mg/day
- Estradiol skin patch 4–8 mg twice weekly
- Estradiol plus testosterone

Male Patients (any one)

- Testosterone enanthate 200 mg IM every 2–3 weeks
- Testosterone skin patch 2.5–5.0 mg/day can increase dose up to 7.5 mg/day
- Testosterone gel 3–6 g daily

Growth hormone

- *Adults*: Recombinant human GH (rhGH) starting dose 2–5 µg/kg subcutaneously daily. This weight-based recommendation is for the starting dose only. The goal should be to start with low doses and increase gradually until the serum IGF-1 concentration is normal.
- *Children*: Recombinant human GH (rhGH) is 0.16–0.24 mg/kg/week, divided into once daily injections. Further adjustments of GH dose based on growth response, serum insulin-like growth factor-1 (IGF-1) levels, and body weight.

Thyroid-stimulating hormone

L (levo)-thyroxine dose of 1.6 µg/kg daily and adjusting dose according to serum free T_4 levels in upper half of reference range.

Vasopressin

- Intranasal desmopressin-rhinal tube 5–20 µg twice daily
- Oral DDAVP (desmopressin) 300–600 µg daily, usually in divided doses

Prolactin

Recombinant human prolactin (r-hPRL), although not commercially available, has been used experimentally.

Treatment of Sheehan's syndrome

Control of hemorrhage and volume replacement. Administration of deficient hormones. Prolactin deficiency results in inability to breastfeed, but no treatment is available.

Empty Sella Syndrome

Q. Write a short note on empty sella syndrome.

- Often an **incidental MRI** finding **(Fig. 13.1)**.
- In this condition, **herniation of arachnoid diverticulum** through an incomplete diaphragm sellae results in symmetrically ballooned sella, which gets filled up with cerebrospinal fluid (CSF).
- Usually have **normal pituitary function**, implying that the surrounding rim of pituitary tissue is fully functional.
- An empty sella can be a primary congenital weakness of the diaphragm or secondary subsequent to infarction of a pituitary adenoma or to surgical or radiation-induced damage to the sellar diaphragm.
- **Hypopituitarism** may develop insidiously.
- Common in obese, multiparous women with chronic headache.
- Rarely, functional pituitary adenomas may arise within the rim of pituitary tissue, and these are not always visible on MRI.

Kallmann Syndrome

Q. Write a short note on Kallmann syndrome.

- It is due to **defective hypothalamic gonadotropin-releasing hormone synthesis**.
- Olfactory bulb agenesis or hypoplasia is associated with **anosmia or hyposmia**.
- Conditions associated with this are color blindness, optic atrophy, cleft palate, renal abnormalities, cryptorchidism, and neurologic abnormalities like synkinesis or mirror movements.
- The deficiency **prevents progression through puberty** due to **low LH and FSH levels and sex steroids.**
- **Males**: Delayed puberty and hypogonadism, including micropenis. Replacement by human chorionic gonadotropin (hCG) or testosterone for a long-term is needed.
- **Female:** It manifests as **primary amenorrhea** and failure of secondary sexual development. Long-term treatment with estrogen and progestin is warranted.

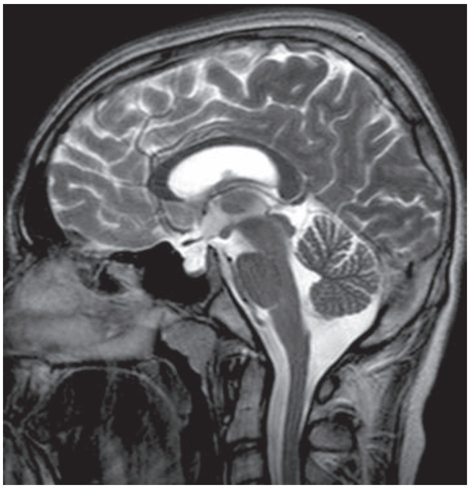

FIG. 13.1: MRI image of empty sella.

Growth Hormone Therapy (Table 13.3)

Q. Lists the indications and side effects of growth hormone therapy.

- **Route of administration of GH:** Subcutaneously after 8.00 PM, 3-7 times a week (0.15-0.3 mg/kg/week).
- Effect is dose-dependent and the response is better if started earlier. Average increment in height = 10 cm/year.
- Better response in classic growth hormone deficiency (GHD).

TABLE 13.3: Indications and side effects of growth hormone therapy.

Indications	***Side effects***
GH (growth hormone) deficiency	Edema
Intrauterine growth retardation (IUGR)	Arthralgia
Non-GH deficient short stature FSS (familial short stature), CGD (constitutional growth delay)	Myalgia, muscle stiffness
Chronic renal failure	Paresthesia
Burns	Carpal tunnel syndrome
Steroid therapy	Hypertension
Osteoporosis	Melanocytic nevi
HIV-associated cachexia	Hypothyroidism
Sports abuse	

Pituitary Apoplexy

Q. Write a short note on pituitary apoplexy.

Pituitary apoplexy is a rare life-threatening endocrine **emergency** characterized by a sudden onset of headache, visual symptoms, altered mental status, and hormonal dysfunction due to **acute hemorrhage** or **infarction** of the pituitary gland.

Management of Pituitary Apoplexy

- **Initial management: Conservative** with careful monitoring of fluid and electrolyte balance along with immediate replacement of deficient hormones, in particular corticosteroids. Close monitoring of vision. High-dose corticosteroids and supportive treatment needed.
- **Surgical decompression:** If there is a rapid deterioration in visual acuity and fields, surgical decompression of the optic chiasm may be required.
- May also improve spontaneously, as blood is resorbed, over a course of weeks to months after the hemorrhage.
- For patients with a lactotroph adenoma, administration of a dopamine agonist to reduce adenoma size.

Clinical Features

- Sudden severe headache, double vision, and sudden severe visual loss.
- Cardiovascular collapse, change in consciousness, neck stiffness, and sometimes hypoglycemia. Sometimes acute life-threatening hypopituitarism.
- GnRH deficiency is most common. Acute adrenal insufficiency is common due to loss of ACTH. TSH deficiency occurs in half of the patients.
- The condition can evolve over 1–2 days.

- **CT/MRI findings:** Pituitary imaging without contrast (CT or MRI) usually reveals signs of intrapituitary or intra-adenoma hemorrhage, "**pituitary ring sign**" on T1-weighted MRI, stalk deviation and compression of normal pituitary tissue and, in severe cases, signs of parasellar subarachnoid hemorrhage (**Fig. 13.2**).

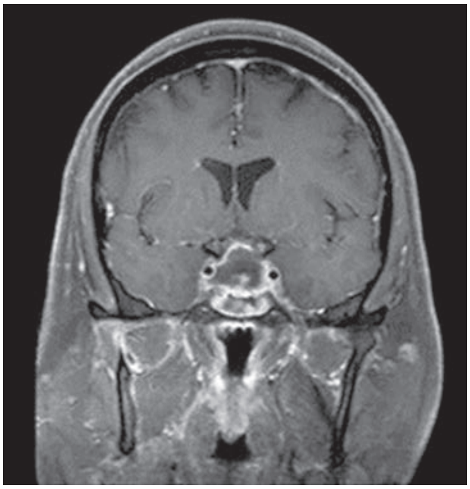

FIG. 13.2: CT/MRI findings: Pituitary imaging. "**pituitary ring sign**"—pituitary apoplexy.

Pituitary Tumors

Q. Write short essay/note on clinical manifestation, investigations, and management of pituitary tumors.

Pituitary tumors are the most common cause of pituitary disease, and most of them are benign pituitary adenomas.

Classification

- Pituitary tumors are classified depending on the tumor size into **microadenomas** (<1 cm in diameter) and **macroadenomas** (exceed 1 cm in diameter).
- Pituitary adenomas may be **functional** (i.e., associated with hormone excess and clinical manifestations thereof) or **nonfunctional** (i.e., without clinical symptoms of hormone excess). Nonfunctional tumors detected incidentally during MRI/CT examination or at autopsy are called as pituitary **incidentalomas**.

Various tumors of pituitary are listed in **Table 13.4**. Other tumors of pituitary are listed in **Box 13.3**.

TABLE 13.4: Pituitary tumors, hormone produced and their associated disorder.

Pituitary adenomas	*Hormone produced*	*Associated disorder*
Lactotroph adenoma (Prolactinoma)	Prolactin	Hypogonadism, galactorrhea, and amenorrhea (in females)
Somatotroph adenoma	Growth hormone	Acromegaly (adults) and gigantism (children)
Corticotroph adenoma	Adrenocortico-tropic hormone (ACTH) and other POMC-derived peptides	Cushing's disease
Gonadotroph adenoma	Follicle-stimulating hormone (FSH) and luteinizing hormone (LH)	Mass effects, hypopituitarism
Thyrotroph adenoma	Thyroid-stimulating hormone (TSH)	Hyperthyroidism
Mammosomatotroph adenoma	Prolactin, GH	Combined features of GH and prolactin excess
Nonfunctioning/null cell adenoma	None	Mass effects, hypopituitarism

Clinical Features

The signs and symptoms may be due to mass effects and endocrine abnormalities.

- **Mass effects:** Mass effects of the enlarging tumor can produce specific signs and symptoms of hypofunction by pressure effect on surrounding normal pituitary tissue (see hypopituitarism). The mass effect on the neighboring structures causes:
  - **Due to stretching of the diaphragm sellae or by invasion of bone:** It causes **headache** and is common (especially in patients with macroadenomas) but non-specific.
  - **Due to pressure effects on optic chiasma, nerve or tract: Visual field abnormalities** which include loss of acuity and optic atrophy (superior temporal quadrantanopia or temporal hemianopia).
  - **Due to lateral extension into cavernous sinus** with subsequent compression of cranial nerve which produces **palsies** of cranial **nerves III, IV, and VI.** This results in diplopia and strabismus and facial numbness.
  - **Due to mass effects on hypothalamus:** Obesity, disturbances of sleep, thirst, appetite, temperature regulation, and diabetes insipidus (DI).
  - **Others:** Anosmia (frontal lobe involvement), vomiting, papilledema (raised intracranial tension).
  - **Occasionally**, pituitary tumors infarct or bleeding into produces "**pituitary apoplexy**".
- **Clinical features due to secretion of hormones** (**Table 13.4**).

Box 13.3: Other tumors of pituitary.

Benign	*Malignant*
Craniopharyngioma	Germ cell tumors
Meningioma	Chordomas
Pituicytoma	Primary lymphoma
	Metastases

As a component of multiple endocrine neoplasia type I (MEN-I), which includes parathyroid, pancreatic, and pituitary (usually prolactinoma) tumors.

Investigations

- **Plain radiograph of the pituitary fossa (skull):** It may show one or more of the following:
  - Enlargement of sella turcica
  - Calcification of suprasellar region
  - Erosion of clinoid process
  - Double floor of the sella.
- **CT scan with contrast enhancement:** More sensitive to detect bony erosions and presence of calcification.
- **Magnetic resonance imaging (MRI) of the pituitary:** MRI with gadolinium **(imaging method of choice)** is superior to CT scanning and shows pituitary mass. If gadolinium is contraindicated, such as renal impairment or pregnancy, MRI without gadolinium may still be helpful. Small lesions within the pituitary fossa (small pituitary microadenomas) are very common. Such small lesions are sometimes detected during MRI scanning of the head for other reasons and are called **"pituitary incidentalomas" (Fig. 13.3)**.
- **Visual field plotting** by automated computer perimetry or Goldmann perimetry.
- **Functional assessment of the pituitary gland:** By hormonal assays and include prolactin (lactotroph adenomas), IGF-1 (somatotroph adenomas), 24-hour urinary-free cortisol (corticotroph adenomas), plasma corticotropin (ACTH), FSH, LH, free T_4, and thyroid function tests.

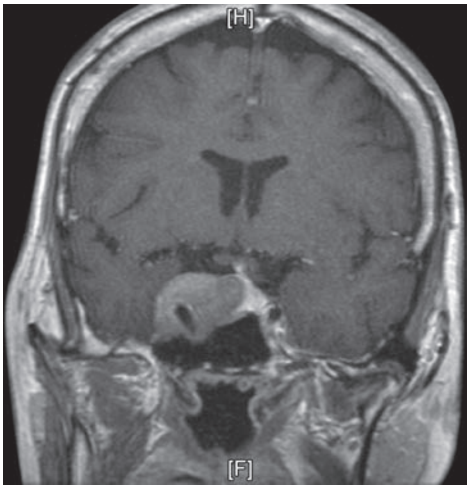

FIG. 13.3: MRI showing right-sided sellar mass displacing the normal pituitary gland to the left.

Treatment of pituitary tumors

Surgery

- Surgery (except for prolactinomas) is the **primary mode of treatment** for pituitary tumors that warrant intervention.
- Surgery via the **trans-sphenoidal** adenomectomy or hypophysectomy is the treatment of choice.
- Very large tumors are removed via the open **transcranial** (usually transfrontal) route. It is usually performed by an endoscopic or endonasal approach.

Medical therapy

Somatostatin analogs and/or dopamine agonists: Octreotide is administered postresection. Drug therapy with dopamine agonists such as bromocriptine and cabergoline are effectively used in the management of prolactinomas. They induce a rapid fall in PRL levels and can decrease the size of tumor and possibly avoid surgery.

Radiation therapy

It is usually **used as adjunctive therapy after surgery** or when surgery is impracticable or incomplete or in **combination with medical therapy**. Includes **external radiotherapy, or implantation of Yttrium** in the pituitary fossa, or gamma knife or a modified linear accelerator.

- It suppresses the tumor growth and reduces its secretory capacity.
- **Gamma knife** (stereotactic radiosurgery) involves precise delivery of large single high-energy dose directly to the tumor under stereotactic surgery and is particularly useful for residual tumor in the cavernous sinus.

Acromegaly

Q. Write short essay/note on acromegaly and its major clinical signs.

- **Growth hormone (GH)** is required for proper growth and development. It directly affects metabolism of fat and indirectly effects bone growth.
- Acromegaly results from **persistent hypersecretion** of growth hormone (GH). Excess GH stimulates hepatic secretion of **insulin-like growth factor-1 (IGF-1)**, which causes most of the clinical manifestations of acromegaly.
- Excess secretion of GH prior to closure of epiphyseal growth plates in long bone before onset of puberty causes **pituitary gigantism**. Excess secretion **after puberty** causes **acromegaly**.
- Males and females are equally affected.
- Most deaths are due to heart failure, coronary artery disease, and hypertension-related causes. Patients with acromegaly have an increased risk for cancer (i.e., carcinoma colon).

Etiology of Acromegaly

Excess of growth hormone (GH excess) after puberty may be due to**:**

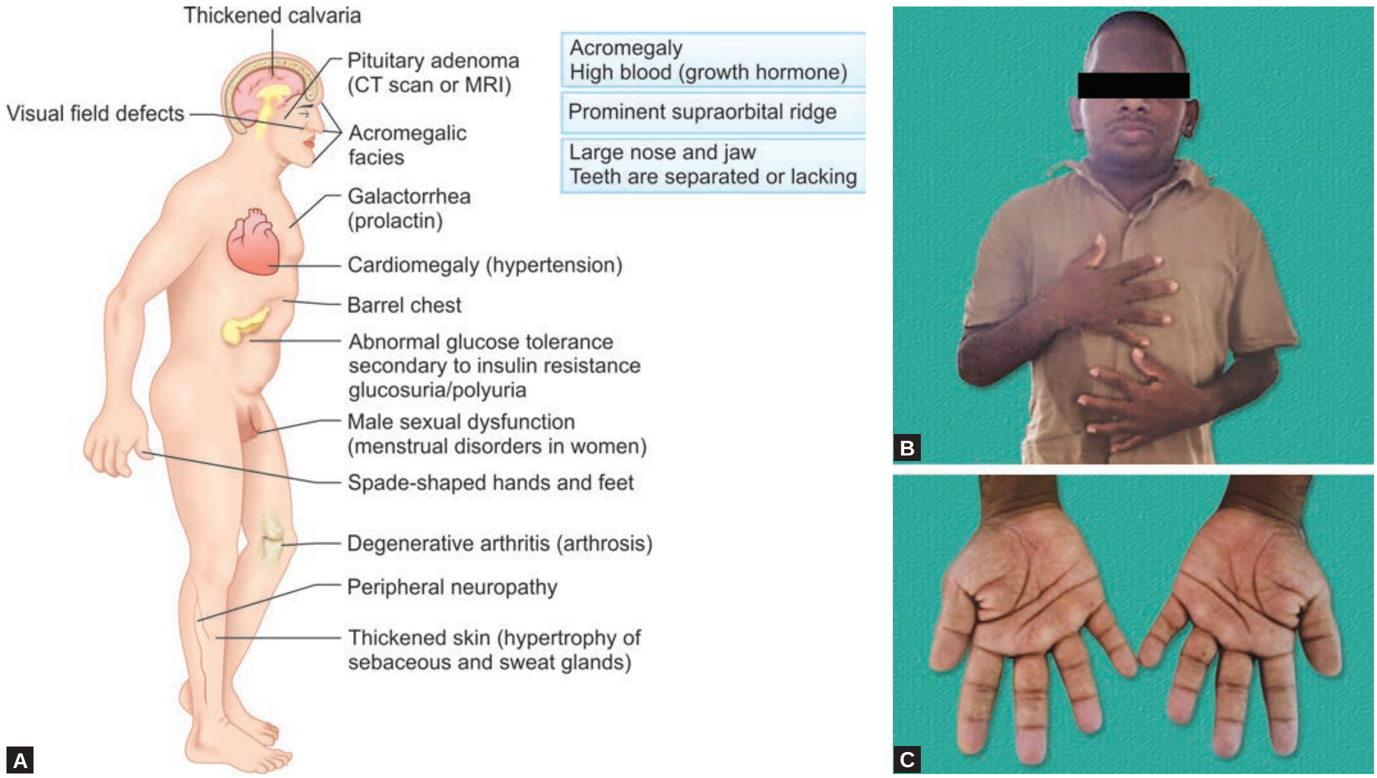
- **Pituitary tumor (somatotrope pituitary adenoma)** is the **most common cause**. Acromegaly is caused by growth hormone (GH) secretion usually from a macroadenoma of pituitary gland. Few adenomas secrete both GH as well as prolactin.
- **Other tumors:** In a few patients, acromegaly is caused by tumors of the **pancreas, lungs, and adrenal glands** (either because they produce GH themselves or, more frequently they produce GHRH, the hormone that stimulates the pituitary to make GH).

Clinical Features (Figs. 13.4A to C and Table 13.5)

Clinical features are due to increased GH (growth hormone) and IGF-1 (insulin-like growth factor-1).

Investigations

- The diagnosis of acromegaly should be suspected in individuals who present with the typical clinical features of growth hormone (GH) excess, which include the enlargement during adulthood of the jaw (macrognathia), hands, and feet, which result in increasing shoe and glove size and the need to enlarge finger rings.
- **Biochemical investigations**
  - **Insulin-like growth factor-1 (IGF-1) levels:** It is the **single best test** useful in diagnosis. IGF-1 is almost always elevated in acromegaly **(Flowchart 13.1)**.
  - **GH levels:** Confirmed by assessment of GH secretion. Basal fasting GH levels are >10 ng/mL (465 pmol/L) (normal, 1–5 ng/mL, 46–232 pmol/L) in >90% of patients and range from 5 ng/mL (232 pmol/L) to >500 ng/mL (23,000 pmol/L), with a mean of approximately 50 ng/mL (2,300 pmol/L).
  - **Oral glucose tolerance test:** The **most specific dynamic test** for establishing the diagnosis of acromegaly. GH levels are measured before and 2 hours after an OGTT. In normal subjects, serum GH concentrations fall to 1 ng/mL or less within 2 hours of ingestion of 75 g glucose. **The criterion for the diagnosis of acromegaly is a GH concentration of >1 ng/mL.** Some patients may show a paradoxical rise and about 25% of patients with acromegaly have a positive diabetic glucose tolerance test.



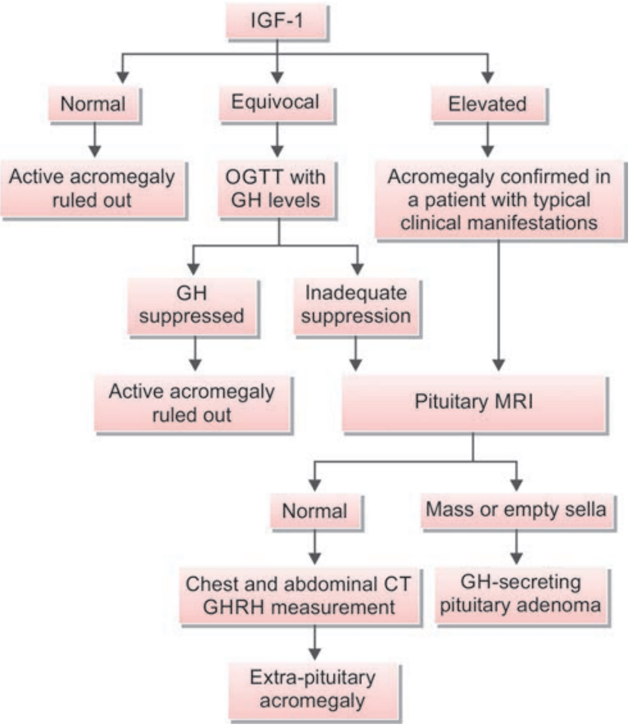
Thickened calvaria
Pituitary adenoma (CT scan or MRI)
Visual field defects
Acromegalic facies
Acromegaly
High blood (growth hormone)
Prominent supraorbital ridge
Large nose and jaw
Teeth are separated or lacking
Galactorrhea (prolactin)
Cardiomegaly (hypertension)
Barrel chest
Abnormal glucose tolerance secondary to insulin resistance glucosuria/polyuria
Male sexual dysfunction (menstrual disorders in women)
Spade-shaped hands and feet
Degenerative arthritis (arthrosis)
Peripheral neuropathy
Thickened skin (hypertrophy of sebaceous and sweat glands)
A
B
C

FIGS. 13.4A TO C: Clinical features of acromegaly. (A) Summary of various clinical features (diagrammatic); (B) Acromegalic facies; (C) Thick and spade-shaped hands.

TABLE 13.5: Various systems involved in acromegaly and presenting features.

System/tissue involved	*Features*
Local tumor effects	Pituitary enlargement, visual-field defects, cranial nerve palsy, headache
Somatic systems	Acral enlargement including thickness of soft tissue of hands and feet
Musculoskeletal system and neurological	Gigantism, prognathism, jaw malocclusion, widely spaced teeth, arthralgias and arthritis, carpal tunnel syndrome, acroparesthesia, proximal myopathy, hypertrophy of frontal bones, osteoporosis
Skin and integumental	Skin tags, acanthosis nigricans, increased sweat and sebum resulting in moist and oily skin, enlargement of lips, nose, and tongue, and increased heel pad thickness
Gastrointestinal system	Macroglossia, colonic polyps, visceromegaly, and pancreatic cancer
Cardiovascular system	Left ventricular hypertrophy, asymmetric septal hypertrophy, cardiomyopathy, hypertension, congestive heart failure, and coronary artery disease
Pulmonary system	Sleep disturbances, sleep apnea (central and obstructive), and narcolepsy
Visceromegaly	Tongue, thyroid gland, salivary glands, liver, spleen, kidney, and prostate
Reproduction	Menstrual abnormalities, galactorrhea, decreased libido, impotence, low levels of sex hormone-binding globulin, and gynecomastia
Multiple endocrine neoplasia type 1	Hyperparathyroidism, pancreatic islet cell tumors
Carbohydrate metabolism	Impaired glucose tolerance, insulin resistance and hyperinsulinemia, and diabetes mellitus
Lipid	Hypertriglyceridemia
Mineral	Hypercalciuria, increased levels of 25-hydroxyvitamin D_3, urinary hydroxyproline levels increased
Electrolyte	Low renin levels, increased aldosterone levels
Thyroid	Low thyroxine binding globulin levels, goiter

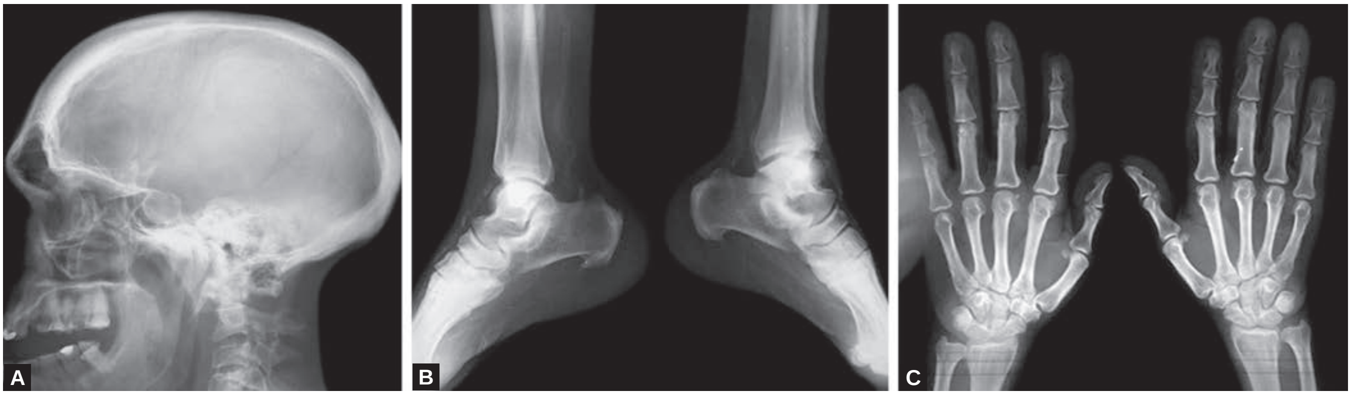
FLOWCHART 13.1: Algorithm for the diagnosis of acromegaly.



IGF-1
Normal
Equivocal
Elevated
Active acromegaly ruled out
OGTT with GH levels
Acromegaly confirmed in a patient with typical clinical manifestations
GH suppressed
Inadequate suppression
Active acromegaly ruled out
Pituitary MRI
Normal
Mass or empty sella
Chest and abdominal CT GHRH measurement
GH-secreting pituitary adenoma
Extra-pituitary acromegaly

(IGF-1: Insulin growth factor-1; GH: Growth hormone; OGTT: Oral glucose tolerance test; GHRH: Growth hormone-releasing hormone)

    - **Serum insulin-like growth factor binding protein-3 (IGFBP-3)** concentrations are elevated in patients with acromegaly.
    - **Thyrotropin-releasing hormone (TRH),** in a dose of 500 µg intravenously, raises serum GH concentrations by 50% or more in approximately one-half of patients with acromegaly, with peak values occurring at 20-30 minutes of administration.
    - **L-DOPA** (500 mg orally) reduces serum GH concentrations by 50% or more in approximately one-half of patients with acromegaly, while it raises the GH concentration in normal subjects.
    - **Postprandial plasma glucose** may be **elevated** and serum insulin is increased in 70% of patients.
    - **Prolactin:** Shows mild-to-moderate elevation in about 30% of patients due to **cosecretion of prolactin** from the tumor.
    - **Others:** Elevated serum phosphorus.
- **Radiological investigations**
    - **MRI of pituitary**: If the biochemical tests are abnormal and GH hypersecretion is confirmed, MRI will almost always reveal and localize the pituitary adenoma usually a somatotroph adenoma (most common cause of acromegaly). If the MRI is normal, abdominal, chest imaging or DOTATATE positron emission tomography (PET) scan should be performed to look for an ectopic source of hormone secretion.
    - **X-ray (Figs. 13.5A to C):**
        - **Plain films of skull:** Shows **sellar enlargement** in 90% of cases. Other findings may be **thickening of the calvarium, enlargement of the frontal and maxillary sinuses**, and **enlargement of the jaw**.



FIGS. 13.5A TO C: X-ray findings in acromegaly. (A) Lateral X-ray skull showing sellar enlargement, thickening of the calvarium, enlargement of the frontal and maxillary sinuses, and enlargement of the jaw; (B) X-ray ankle shows increased thickness of the heel pad in acromegaly; (C) X-ray of hand showing increased soft tissue bulk, "arrowhead" tufting of the distal phalanges.

  - ♦ **Radiographs of the hand:** Shows increased **soft tissue bulk, "arrowhead" tufting** of the distal phalanges, **increased width of intra-articular cartilages**, and **cystic changes** of the carpal bones.
  - ♦ **Radiographs of the feet:** Shows similar changes to that of hand, and there is **increased thickness of the heel pad** (normal heel pad thickness <22 mm).
  - ♦ **X-ray of spine: Scoliosis, calcification of spinal ligaments.**
- **Pituitary function:** Partial or complete anterior hypopituitarism is common.
- **Visual field examination:** Defects are common (e.g., bitemporal hemianopia)

Treatment of Acromegaly

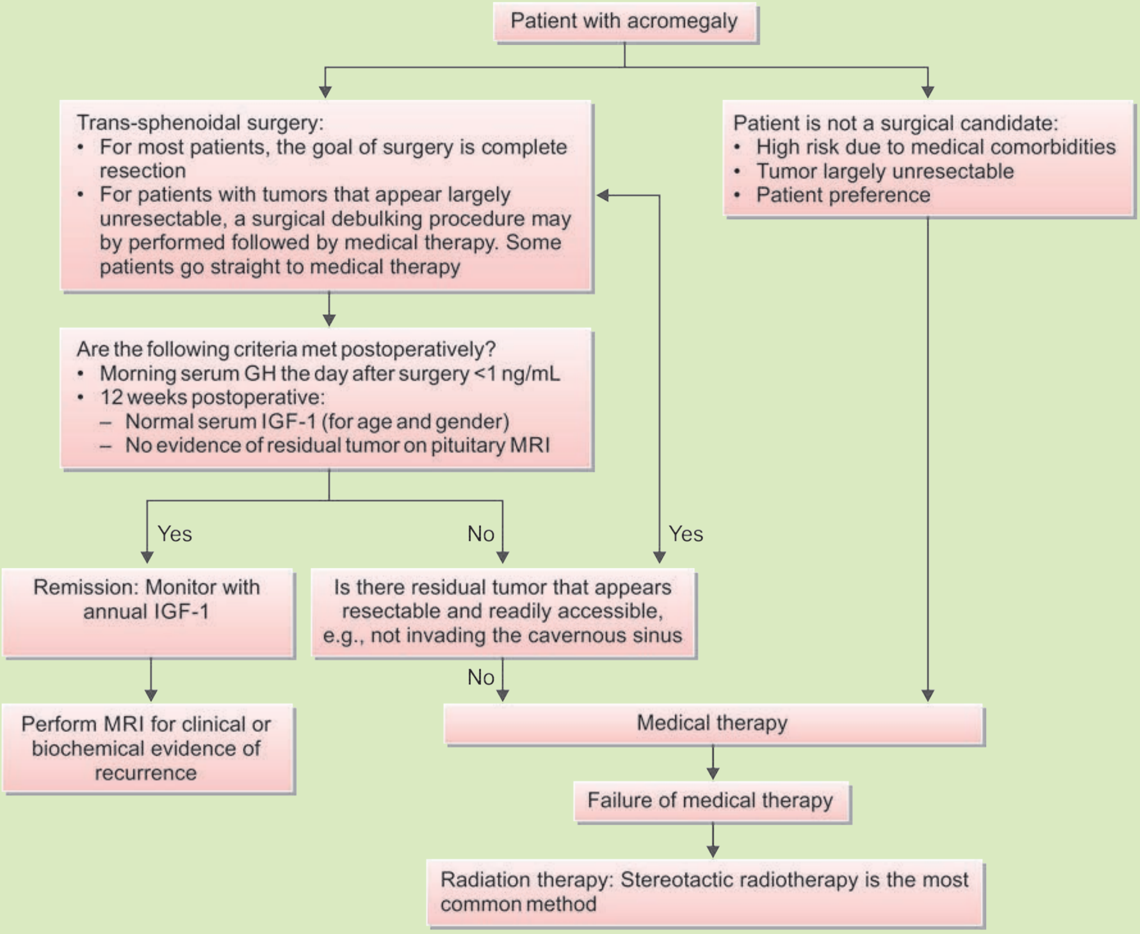
- **Goals of therapy:**
  - – To lower the serum insulin-like growth factor-1 (IGF-1) concentration
  - – Control adenoma size and reduce mass effects
  - – Improve symptoms
  - – Reverse metabolic abnormalities such as diabetes mellitus
- **Aim of therapy:**
  - – To lower the serum IGF-1 concentration to within the normal range for the patient's age and gender.
  - – Control adenoma size and reduce mass effects.
  - – Alleviate symptoms such as headaches, vision loss without causing hypopituitarism.
  - – Reverse metabolic abnormalities such as diabetes mellitus.
  - – To lower the serum growth hormone (GH) concentration to <1 µg/L

1. **Surgery: Trans-sphenoidal surgical removal** of pituitary adenoma is the first-line therapy.
2. **Medical therapy: Indication for primary medical management (Flowchart 13.2):** Patients
   - – With no risk of visual impairment from the tumor
   - – Unfit candidates for surgery and those who decline surgery
   - – Tumors that are unlikely to be controlled by surgery
   - – Persistence of acromegaly after surgery
   - – Require preservation of intact pituitary function (especially fertility).

   Drugs used: There are three receptor targets for the treatment of acromegaly.

   a. **Somatostatin receptor ligands (SRL)**
      - ♦ About 90% growth-hormone secreting adenomas express somatostatin receptor subtypes (SSTR), SSTR2, and SSTR5.
      - ♦ **Mode of action:** Somatostatin analogs (**Octreotide, Pasireotide or Lanreotide**) are more effective than dopamine agonists and act on pituitary somatostatin receptors to produce inhibition of GH and IGF-1.
      - ♦ **Limitations:** Costly, transient diarrhea, nausea, and abdominal discomfort due inhibition of motor activity, gallstones, and hair loss <10%.

   b. **GH receptor antagonist**
      - ♦ **Pegvisomant** is a GH receptor antagonist, blocks peripheral IGF-1 action in almost all patients, and is indicated in patients who are inadequately controlled with other modalities or in patients experiencing clinically significant drug side effects.



FLOWCHART 13.2: Management of the patient with acromegaly.

Patient with acromegaly
Trans-sphenoidal surgery:
• For most patients, the goal of surgery is complete resection
• For patients with tumors that appear largely unresectable, a surgical debulking procedure may by performed followed by medical therapy. Some patients go straight to medical therapy
Patient is not a surgical candidate:
• High risk due to medical comorbidities
• Tumor largely unresectable
• Patient preference
Are the following criteria met postoperatively?
• Morning serum GH the day after surgery <1 ng/mL
• 12 weeks postoperative:
– Normal serum IGF-1 (for age and gender)
– No evidence of residual tumor on pituitary MRI
Yes
No
Yes
Remission: Monitor with annual IGF-1
Is there residual tumor that appears resectable and readily accessible, e.g., not invading the cavernous sinus
No
Perform MRI for clinical or biochemical evidence of recurrence
Medical therapy
Failure of medical therapy
Radiation therapy: Stereotactic radiotherapy is the most common method

(IGF-1: Insulin growth factor-1; GH: Growth hormone)

- ◆ **Limitations:** Daily injection, costly, acts on peripheral tissues, and neither affects pituitary tumor nor secretion of GH, GH raises 76% due to loss of negative feedback by lower IGF-1 levels, and LFTs to be monitored due to elevated levels of AST.

c. **Dopamine receptor agonists:** Act on D_2 receptors. **Bromocriptine or cabergoline** are dopamine receptor agonists and are useful in those with mildly elevated IGF-1.

3. **Radiotherapy**
   - **Indications:** It is usually employed as second-line treatment
     - If acromegaly persists after surgery
     - In patients who are not fit candidates for surgical therapy
     - In whom medical therapy fails.
   - External radiotherapy or implantation of Yttrium into the gland.
   - Stereotactic radiosurgery (gamma knife and cyber knife).
4. **Others:** Treatment of associated conditions such as diabetes, hypertension, and hyperlipidemia.

Prolactinoma

Q. **Write short essay/note on:**

- **Prolactinoma and hyperprolactinemia.**
- **Causes, clinical features, investigations, and treatment of hyperprolactinemia.**

- **Prolactinoma** is a pituitary tumor that produces prolactin.
- Most common functional pituitary tumor. Most of these tumors are microadenomas.
- Elevated level of plasma prolactin is known as **hyperprolactinemia.**

Causes of Hyperprolactinemia (Box 13.4)

Clinical features

Hyperprolactinemia stimulates **milk production in the breast** and **inhibits GnRH and gonadotropin secretion**. It usually presents with:

- **Hypogonadism, decreased libido, infertility**, and **galactorrhea** (spontaneous or expressible) in both sexes.
- **In females: Amenorrhea, oligomenorrhea,** and **osteoporosis.**
- **In males: Hypogonadotropic hypogonadism** leading to loss of libido, impotence, infertility, gynecomastia, and rarely galactorrhea.
- A sufficiently large macroadenoma usually produces visual field defects and headache.

Box 13.4: Causes of hyperprolactinemia.

Physiological

- Pregnancy
- Stress
- Nursing
- Nipple stimulation

Pathological

A. **Drug-induced:** Estrogens, opiates, dopamine-receptor antagonists (phenothiazines, butyrophenones, metoclopramide), and dopamine-depleting agents (reserpine and methyldopa)

B. **Disease states**
  - Pituitary adenomas (lactotroph, somatotroph-lactotroph, and stalk compression by chromophobe tumors)
  - Hypothalamic and stalk disease (craniopharyngiomas, irradiation, granulomas, and stalk section/compression)
  - Primary hypothyroidism
  - Miscellaneous (cirrhosis, chronic renal failure, and seizures)

Investigations

The investigation of prolactinomas is the same as for other pituitary tumors discussed above.

- **Normal range for serum prolactin is approximately 5-20 µg/L.**
- The diagnosis of hyperprolactinemia is made by a serum prolactin concentration that is well above the normal range >**20** µg/L in men and postmenopausal women and >**30 µg/L in premenopausal women**.
- Serum PRL over 150 µg/L in a nonpregnant woman is generally due to pituitary adenoma.
- Level of over 300 µg/L is almost diagnostic of tumor (even in a nursing mother).
  - **Hook effect:** Caution should be exercised in interpreting serum prolactin concentrations between 20 and 200 µg/L in the presence of a macroadenoma because of possible artifactually low values due to the "hook effect". This effect occurs when a very high serum prolactin, e.g., 5,000 µg/L, saturates both the capture and signal antibodies used in immunoradiometric and chemiluminescent assays, preventing the binding of the two in a "sandwich". The result is an apparent prolactin concentration that is only modestly elevated, suggesting that the macroadenoma is clinically nonfunctioning. The artifact can be avoided by repeating the assay using a 1:100 dilution of serum.
  - **Macroprolactin**: Macroprolactin is native prolactin that is bound to IgG. This causes hyperprolactinemia through decreased prolactin clearance.
- **Visual fields** should be checked.
- **Primary hypothyroidism** must be excluded.
- **Anterior pituitary function** should be assessed if there is evidence of hypopituitarism or radiological evidence of a pituitary tumor.
- **MRI or contrast-enhanced CT scan of the pituitary:** It is needed if there are any clinical features suggestive of a pituitary tumor. It is desirable when prolactin is significantly elevated (above 1,000 mU/L). It can easily delineate macroprolactinoma (tumors above 10 mm diameter), but microprolactinoma (smaller ones) may be more difficult to delineate.

Treatment of prolactinoma

Hyperprolactinemia is usually treated to **prevent the long-term effects of estrogen or testosterone deficiency.**

- **Medical treatment by dopamine agonists:**
  - **Cabergoline** is the first choice with a dose of 0.25–0.5 mg twice a week.
  - **Bromocriptine** (1.25–2.5 mg twice daily) reduces the secretion of prolactin as well as size of pituitary tumor.
  - **Quinagolide:** Initial: 0.025 mg once daily for 3 days followed by 0.05 mg once daily for 3 days. Maintenance (beginning on day 7): 0.075 mg once daily
- **Treatment of men:** Testosterone.
- **Treatment of women:** Estradiol.
- **Trans-sphenoidal removal:** It is indicated if dopamine agonists fails or in the presence of a large, invasive tumor.
- **External radiotherapy:** Rarely necessary.
- **Asymptomatic patients** who do not require restoration of pregnancy give estrogens to prevent bone loss and should be regularly monitored.

Diabetes Insipidus (DI)

Arginine vasopressin deficiency (AVP-D) is the new name for central diabetes insipidus, and arginine vasopressin resistance (AVP-R) is the new name for nephrogenic diabetes insipidus.

Q. **Write a short note on diabetes insipidus (DI) and its diagnosis.**

Q. PM8.4 **Describe metabolic co-morbidities like SIADH, diabetes mellitus, insipidus and endocrine dysfunction following TBI.**

- Diabetes insipidus (DI) is a disorder in which **polyuria** due to **decreased collecting tubule water reabsorption** is induced by either **decreased secretion of antidiuretic hormone** (ADH; central DI) or **resistance to its renal effects** (nephrogenic DI).
- It is characterized by the persistent passage of **excessive amounts of dilute urine** and thirst.

Types of Diabetes Insipidus (DI)

- **Arginine vasopressin deficiency (AVP-D)/primary deficiency** (neurogenic, pituitary, hypothalamic, cranial or central DI): It is due to agenesis or destruction of neurohypophysis.
- **Secondary deficiency:** It is due to inhibition of ADH secretion (primary polydipsia).
- **Deficient action of ADH: Arginine vasopressin resistance (AVP-R)**/(nephrogenic DI)
- Transient **diabetes insipidus of pregnancy** produced by accelerated metabolism of vasopressin by **vasopressinase** released from the placenta (gestational DI).

Causes of Diabetes Insipidus (Table 13.6)

Clinical features

- **Polyuria and polydipsia:** The urine output may range from 2 L/day with mild partial DI to over 10–15 L/day in patients with severe disease, nocturia, and compensatory excessive thirst (polydipsia) are the most marked symptoms.
- **Other features:** Change in mentation, insomnia, and weight loss.
- Skin, mucous membranes cool.
- If left untreated changes in LOC (loss of consciousness), tachycardia, tachypnea, and hypotension (shock-like symptoms), but unlike hypovolemic shock, urine output is increased.
- Patients with nephrogenic DI may also have manifestations related to underlying cause such as lithium toxicity, hypercalcemia, and hypokalemia.
- It can lead to **hypernatremia**, restlessness, agitation, diminished deep tendon reflexes, and seizures.

TABLE 13.6: Causes of diabetes insipidus (DI).

Central DI	*Nephrogenic DI*
1. **Idiopathic** (30–50%) 2. **Neoplastic or infiltrative lesions of hypothalamus** (pituitary tumors with suprasellar extension, metastases, leukemia, histiocytosis, craniopharyngioma, lymphoma, sarcoidosis, germinomas, and pinealomas) 3. **Pituitary or hypothalamic surgery** 4. **Severe head injury,** usually associated with skull fracture 5. **Hypoxic encephalopathy** 6. **Ruptured cerebral aneurysms** 7. **Infections** (e.g., encephalitis, TB, etc.) 8. **Autoimmune:** Associated with thyroiditis 9. **Postsupraventricular tachycardia** 10. **Anorexia nervosa** 11. **Familial:** – Autosomal dominant familial neurohypophyseal DI (FNDI) due to mutations in the gene encoding ADH – X-linked inheritance **Wolfram syndrome** (also known as **DIDMOAD** syndrome) characterized by DI, DM, optic atrophy and deafness, septo-optic dysplasia ***Proprotein convertase subtilisin/kexin-type 1 (PCSK1) gene deficiency***	1. **Primary/congenital or familial:** – X-linked recessive vasopressin receptor V2 mutation – Autosomal dominant or autosomal recessive aquaporin-2 gene mutation – Autosomal recessive Bardet–Biedl syndrome – Bartter syndrome – Nephronophthisis – Cystinosis – Familial hypomagnesemia with hypercalciuria and nephrocalcinosis (FHHNC) – Autosomal recessive ARC syndrome (arthrogryposis-renal dysfunction-cholestasis) 2. **Acquired:** Chronic pyelonephritis, hypokalemia, hypercalcemia, sickle cell disease, protein deprivation drug-induced (lithium, cidofovir, foscarnet, ifosfamide, ofloxacin, orlistat, demeclocycline, didanosine, amphotericin B, aminoglycosides, cisplatin, rifampicin, colchicine), amyloidosis, other renal diseases (chronic renal failure, obstructive uropathy, polycystic disease), Sjögren's syndrome, postsurgery for craniopharyngioma, and pregnancy

Complications

- Hypernatremia, dehydration, and their neurological sequelae
- Growth retardation
- Hydronephrosis (due to excessive urine output)

Investigation and diagnosis

- **Careful history, examination**
- Document presence of **polyuria** (usually 2–15 L/24 hours).
- **Measurement of osmolality of plasma and urine:** It establishes the diagnosis.
    - Normally, plasma osmolality is <295 mOsml/kg and urine osmolality (random specimen) is 50–1,200 mOsml/kg.
    - In patients with DI and excess urine free water, there is **high or high normal plasma osmolality** (>295 mOsml/kg) and **low urine osmolality** (50–150 mOsml/kg).
    - In primary polydipsia, plasma osmolality tends to be low and may be lower than urinary osmolality.
- **Urine:**
    - **High 24 hours urine volumes**. If the volume is <2 L, there is no need for further investigation.
    - **Clear and of low specific gravity** of urine.
    - **Low urine osmolality** and usually less than that of plasma osmolality.
- **Serum sodium is high or high normal** (hypernatremia) and indicates loss of water.
- **MRI of pituitary and hypothalamus** to identify hyperintensities in the posterior pituitary or thickening of the pituitary stalk can help determine the cause of CDI.

Q. Write a short note on water deprivation test.

- **Water deprivation test (Miller-Moses Test) (Fig. 13.6):**
    - **Indication:**
        - Diagnosis or exclusion of diabetes insipidus
        - To differentiate CDI and NDI
        - To differentiate diabetes insipidus from primary polydipsia
    - **Procedure:**
        - Should be done in the morning under observation with 8 hours fasting. No fluids (water deprivation) from 07:30 hours.
        - Measure plasma and urine osmolality, urine volume and weight hourly for up to 8 hours.
        - Abandon fluid deprivation if weight loss is >5%.
        - If plasma osmolality >300 mOsm/kg and/or urine osmolality <600 mOsm/kg, ADH (vasopressin) is given in the dose of 2 µg IM at end of test. Allow free intake of fluids but measure urine osmolality for 2–4 hours.
    - **Normal response:**
        - Withholding fluid in normal individuals, the **plasma osmolality remains within normal range** (275–295 mOsm/kg) while **urine osmolality rises** above 600 mOsm/kg (800–1,200 mOsm/kg).

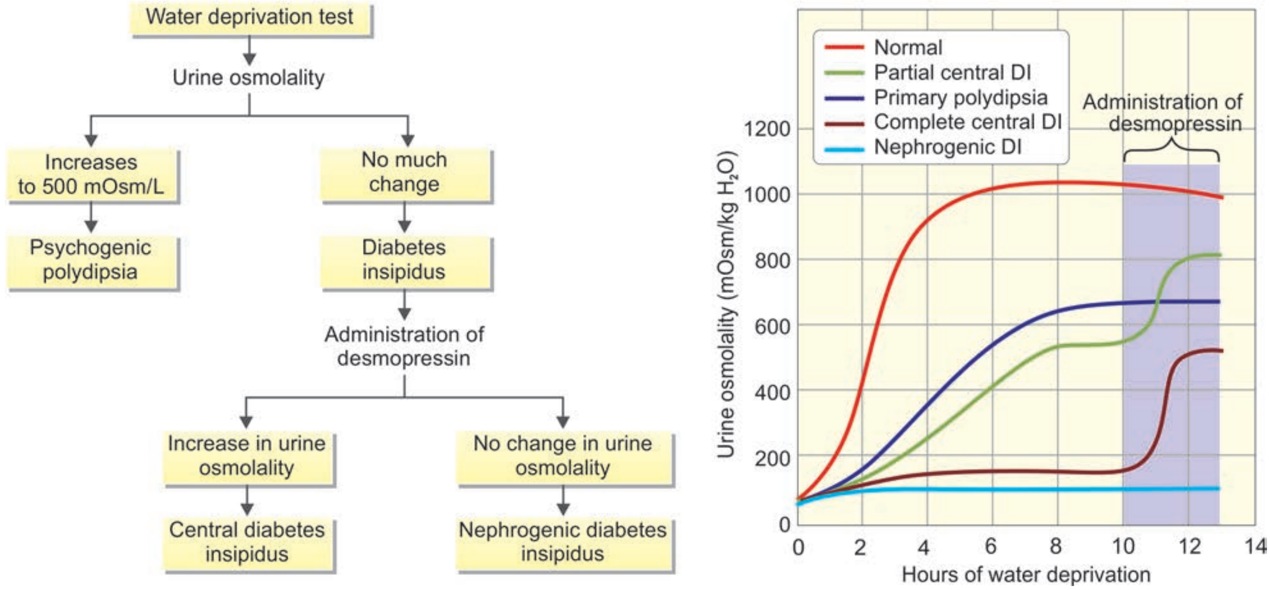


FIG. 13.6: Water deprivation test and its interpretation.

  - **Urine osmolality is greater than plasma osmolality after restriction of water**.
  - Urine osmolality increases minimally (<10%) after exogenous ADH.
- **Primary polydipsia**
  - Patients with primary polydipsia start with low normal plasma osmolality (280 mOsm/kg).
  - **Urine/plasma osmolality ratio rises to >2 after dehydration (water deprivation).**
- **Central diabetes insipidus**
  - After water restriction in patients with DI, the **plasma osmolality rises above normal** (>300 mOsm/kg) **without rise in urine osmolality** (<600 mOsm/kg) or specific gravity of urine. (Normally urine osmolality rises to 1,000–1,200 mOsml/kg after water restriction). Urine osmolality remains less than plasma osmolality and urine/plasma osmolality ratio remains <1.5.
  - After ADH is given, urine osmolality increases 100% in complete CDI and over 50% in partial CDI.
- **Nephrogenic diabetes insipidus**
  - Urine osmolality remains less than plasma osmolality.
  - After ADH, urine osmolality increases by <50%.

- Alternative to water deprivation test is by **infusing hypertonic (5%) saline and measures ADH secretion** in response to increasing plasma osmolality.

Treatment of Arginine Vasopressin Deficiency (AVP-D)

- **Goals of treatment**
  - **Balance fluid intake with output:** In acute cases, rapidly replace fluid and in chronic cases with slow replacement to prevent cerebral edema.
  - Daily weights, accurate intake/output monitoring, urine specific gravity, and osmolality.
- **Drugs**
  - **Intranasal desmopressin (DDAVP):** An initial dose of 5 µg at bedtime can be titrated upward in 5 µg increments depending upon the response of the nocturia and then additional daytime doses added. The daily maintenance dose is approximately 5 to 20 µg once or twice a day (suggested maximum dose 40 µg daily). Desmopressin is safe during pregnancy for both the mother and the fetus.
  - **Chlorpropamide:** Increases the renal responsiveness to vasopressin. Hypoglycemia may develop.
  - **Carbamazepine:** It is an alternate drug which enhances ADH release and raises the sensitivity of the collecting duct to it.
  - **Clofibrate:** It is a lipid lowering agent which stimulates residual ADH production in the hypothalamus, therefore, increasing ADH release from the posterior pituitary.
  - **Nonsteroidal anti-inflammatory drugs (NSAIDs):** Work by inhibiting renal prostaglandin synthesis which are ADH antagonists and also, they decrease the glomerular filtration rate by prostaglandin-mediated effect of afferent arteriole dilation.

Treatment of Arginine vasopressin resistance (AVP-R)

- Provision of adequate fluids especially in cases of impaired thirst, calorie and decreased dietary solute such as low sodium diet.
- Correct the underlying cause.
- **Thiazide diuretics:** These (e.g., hydrochlorothiazide 25 mg once or twice daily with a low sodium diet) are the first-line therapy in nephrogenic DI.
- **Amiloride** (potassium-sparing diuretic)**: Additive effect** with thiazide diuretic and may be particularly beneficial in patients with **reversible lithium nephrotoxicity** by possibly allowing lithium to be continued.
- **Exogenous ADH (DDAVP)**
- **NSAIDs:** Indomethacin

THYROID DISORDERS

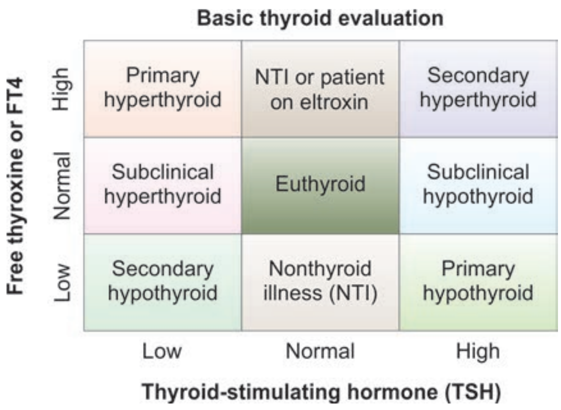
Thyroid Function Tests (TFTs)

Q. IM12.11 Interpret thyroid function tests in hypo- and hyperthyroidism.

Indications for thyroid function tests:

- Screening for thyroid dysfunction.
- **Surveillance:** Women with postpartum thyroiditis, postneck irradiation.
- **Monitoring:** Treatment of hyperthyroidism and hypothyroidism.

Various Thyroid Function Tests (Fig. 13.7)



Basic thyroid evaluation

Free thyroxine or FT4	Low	Normal	High
High	Primary hyperthyroid	NTI or patient on eltroxin	Secondary hyperthyroid
Normal	Subclinical hyperthyroid	Euthyroid	Subclinical hypothyroid
Low	Secondary hypothyroid	Nonthyroid illness (NTI)	Primary hypothyroid

Thyroid-stimulating hormone (TSH)

FIG. 13.7: Basic thyroid evaluation.

Q. Write short essay/note on thyroid stimulating hormone.

- **Serum thyroid-stimulating hormone/thyrotropin (TSH)**
  - It is measured currently by **TSH chemiluminometric assays**.
  - Normal range for serum TSH is approximately **0.4–5.0 mU/L**.
  - **Interpretation**
    - **Thyroid diseases:** As a single test of thyroid function TSH is the most sensitive index of thyroid function.
      - TSH levels can help in **differentiating hyperthyroidism, hypothyroidism, and euthyroidism** (normal thyroid gland function) in most cases.
      - Raised/elevated levels indicate primary hypothyroidism.
      - Low/suppressed levels indicate primary thyrotoxicosis.
    - **Nonthyroid diseases:** Other conditions affecting TSH levels include:
      - TSH-secreting tumors of pituitary
      - Severe nonthyroidal illness (e.g., sick euthyroid syndrome)
      - Low TSH may be observed in first trimester of pregnancy with high doses of corticosteroids and patients ingesting biotin supplements due to assay interference.
      - Secondary hypothyroidism due to hypothalamic-pituitary disease may produce low, normal, or normal-high levels of TSH that are inappropriate for the very low free T_4 level.
- **Thyrotropin releasing hormone (TRH) stimulation test**
  - It may be used in the investigation of **hypothalamic pituitary dysfunction**.
  - Serum TSH is measured before and after the intravenous administration of TRH.
  - **Uses:** To differentiate secondary or tertiary hypothyroidism.
    - Secondary hypothyroidism (pituitary disease): TRH administration does not produce increase in TSH.
    - Tertiary hypothyroidism (hypothalamic disease): TRH administration produces delayed increase in TSH.
    - In primary hypothyroidism, TRH administration produces a prompt increase in TSH.
- **Serum free T_3 (tri-iodothyronine fT_3) and free T_4 (free thyroxine/fT_4)**
  - Advantage of this test compared to the measurement of total T_3 and T_4 is that these are **not influenced by changes in the thyroid hormone-binding globulins (TBG), prealbumin and albumin**. Its level reflects secretory activity.
  - **Primary thyrotoxicosis:** fT_3 and fT_4 levels are elevated.
  - **T_3-thyrotoxicosis:** fT_4 levels are normal and fT_3 levels are elevated.
  - **On T_4 therapy:** fT_4 levels are elevated and fT_3 levels are normal.
- **Total serum thyroxine (tT_4)**
  - Measured by automated competitive binding chemiluminometric assays.
  - Its levels are altered by factors that affect the concentration of TBG.
  - **Normal ranges: 4.6–11.2 µg/dL.**
  - **Increased:** In hyperthyroidism, during pregnancy, estrogen therapy, tamoxifen use and as a congenital anomaly.
  - **Decreased:** In hypothyroidism, nephritic syndrome, androgen therapy, liver failure, or drugs (e.g., salicylates, sulfonylureas, and phenytoin).
- **Total serum tri-iodothyronine (tT_3)**
  - Measured by automated competitive binding chemiluminometric assays.
  - Its levels are subject to the same limitations as for tT_4 in relation to TBG.
  - **Normal range: 75–195 ng/dL.**
- **T_3 resin uptake, free T_4 index (FTI), effective T_4 ratio**
  Nowadays, above three tests (4, 5, and 6) are not used.
- **Reverse T_3 (rT_3)**
  - Reverse T3 (rT3) is mainly an **inactive metabolite of T_4** in peripheral tissues.
  - It has **extremely limited utility** for assessing **rare conditions** such as consumptive hypothyroidism, MCT8 or SBP2 mutations, or possibly distinguishing central hypothyroidism from nonthyroidal illness in critically ill hospitalized patients.

- **Thyroglobulin (Tg)**
  - It is synthesized by follicular cells, secreted into the lumen of the thyroid follicle, stored as a colloid and is involved in iodination/synthesis of thyroid hormones.
  - **Uses:** To predict the **outcome of therapy** for hyperthyroidism.
    - **Increased:** Well-differentiated thyroid carcinoma, hyperthyroidism
    - **Decreased:** Total thyroidectomy or destruction of thyroid by radiation.
- **Uptake of radioactive iodine (RAIU) or technetium**
  - The iodine uptake activity of thyroid can be measured by administering orally a low/trace dose of radioactive iodine **^{131}I or ^{121}I** and the radioactivity over the thyroid is measured after 4 hours, using a counter over the neck.
  - Pregnancy and breastfeeding are **absolute contraindications** to radionuclide imaging. However, in the unusual instance where radioiodine uptake measurement is felt to be essential for a definitive diagnosis in a lactating woman, breast milk can be pumped and discarded for 5 days after ingestion of ^{123}I, then breastfeeding may be resumed; breastfeeding should not be resumed if the I^{131} isotope is used for determining the uptake.
  - The **amount of radioactivity that is taken up** by the thyroid gland is known as radioactive iodine uptake (RAIU). Alternatively, thyroid uptake is measured by giving **technetium-99m (^{99m}Tc) intravenously**.
  - **Uses of radioactive iodine uptake (RAIU)**
    - Evaluation of hyperthyroidism
    - Differentiate Graves's disease from toxic goiter
    - Function of a thyroid nodule as hot or cold
  - **Interpretation: Normal uptake ranges from 10% to 35% in 24 hours.**
    - **Uptake increased: Overactive** thyroid gland synthesizing excess T_3 shows increased uptake of iodine. A very high RAIU is seen in hyperthyroidism (e.g., Graves' disease, toxic multinodular goiter, toxic adenoma and early thyroiditis). Iodine/enzyme deficiency may show increased uptake even in the absence of thyrotoxicosis.
    - **Uptake decreased:** Low RAIU is seen in hypothyroidism and late thyroiditis. Excess iodine may show diminished uptake even in the presence or thyrotoxicosis. Acute autoimmune thyroiditis may manifest as low iodine uptake thyrotoxicosis.
  - **Uses:** To determine **the functional activity and morphology** of the thyroid gland.
    - **Very useful in determining the activity of a solitary thyroid nodule.** Functional nodule appears as a "hot" nodule, and a nonfunctional appears as a "cold" nodule.
    - **Useful in follow-up of patients with treated thyroid cancer.**
    - **Detection of ectopic thyroid tissue:** Confirmation of a mass on the tongue as lingual thyroid in the midline of the neck as thyroglossal duct, or in the mediastinum as substernal goiter.
- **Ultrasound of thyroid gland:** Look for **nodularity, vascularity, shape, microcalcifications, lymph nodes status,** and for **guided FNAC**.
- **Thyroid autoantibody tests:** The different types of thyroid autoantibodies responsible for the autoimmune thyroid disorders are:
  - **Antimicrosomal antibody**
    - **Antithyroid peroxidase (TPO) antibody (TPOAb):** They are involved in the tissue destructive process associated with hypothyroidism in Hashimoto and atrophic thyroiditis.
  - **Antithyroglobulin (Tg) antibody:** May be present in Hashimoto's thyroiditis and Graves' disease.
  - **TSH receptor (TR) antibody (TRAb):** Classified as **stimulating, blocking, or neutral.**
    - Stimulating antibodies (thyroid-stimulating immunoglobulins, TSI) cause Graves' disease.
    - Thyroid receptor-blocking antibodies can cause hypothyroidism.
    - Neutral antibodies bind the receptor but do not stimulate or block function.
- **Tests to determine etiology of thyroid disease**
  - **Calcitonin:** It is secreted by parafollicular C-cells and is increased in medullary carcinoma of thyroid.
  - **Fine-needle aspiration cytology/excision biopsy:** It is helpful in diagnosis thyroid diseases.

Thyrotoxicosis

Q. **Discuss the etiology, clinical features, investigations (laboratory diagnosis), complications and management of hyperthyroidism/thyrotoxicosis.**

Q. **Discuss the etiopathogenesis, clinical features, investigations, diagnosis, and management/treatment modalities of Graves' disease.**

Q. IM12.6 Perform and demonstrate a systematic examination based on the history that will help establish the diagnosis and severity including systemic signs of thyrotoxicosis.

Definition

- **Thyrotoxicosis** is a state of **circulating thyroid hormone excess** (with hypermetabolic state) caused by exposure to **excessive levels of thyroid hormone** (free T_3 and T_4).
- This increase in circulating hormone may be either from destruction of thyroid gland or from ectopic source.
- **Hyperthyroidism** (thyroid overactivity): It is the **clinical consequence due to the excessive circulating thyroid hormone due to excessive thyroid function**/hyperfunction and is the **most common cause of thyrotoxicosis**. Its causes are listed in **Table 13.7A**.

TABLE 13.7A: Causes of hyperthyroidism.

Primary hyperthyroidism	***Thyrotoxicosis without hyperthyroidism***	***Secondary hyperthyroidism***
➢ Graves' disease ➢ Toxic multinodular goiter ➢ Toxic adenoma (Plummer's disease) ➢ Iodine excess (Jod-Basedow) ➢ Activating mutation of TSH receptor	➢ Subacute thyroiditis ➢ Hashitoxicosis ➢ Amiodarone induced ➢ Radiation induced ➢ Thyrotoxicosis factitia ➢ Struma ovarii ➢ Infarction of thyroid gland	➢ TSH secreting pituitary adenoma ➢ hCG-mediated hyperthyroidism (hyperemesis gravidarum, trophoblastic disease) ➢ Gestational thyrotoxicosis

Etiology (Table 13.7B) and Pathogenesis of Hyperthyroidism

Q. Write short essay/notes on causes of hyperthyroidism.

Few of the causes of hyperthyroidism/thyrotoxicosis are discussed below.

1. **Graves' disease**
   - ■ Graves' disease is the **most common form** of thyrotoxicosis. It is characterized by one or more of the following features:
     - ♦ Thyrotoxicosis
     - ♦ Goiter
     - ♦ Orbitopathy (exophthalmos) **(Box 13.5)**
     - ♦ Dermopathy (pretibial myxedema).
   - ■ **Age, gender, and genetic susceptibility:**
     - ♦ It may occur at any age with a peak incidence between **20 and 40 years** of age.
     - ♦ The diseases cluster in families and are **more common in women**.
     - ♦ The concordance rate in monozygotic twins is 20–40%.
     - ♦ Associated with certain alleles of CTLA-4
     - ♦ Associated with certain alleles of HLA on chromosome 6 namely, HLA-DRB1*08 and DRB3*0202.
     - ♦ HLA-DRB1*07 is found to be protective.
   - ■ **Autoantibodies:**
     - ♦ It is an autoimmune disorder with autoantibodies.
     - ♦ **TSI or TSH-receptor antibodies of the stimulating type (TRAb):** IgG type of antibodies directed against the TSH receptors on the follicular cell of thyroid. They stimulate thyroid hormone production and enlargement of thyroid.
     - ♦ **T cells:** Activated T cells release cytokines and increase the secretion of thyroid-specific autoantibodies from B cells. The current concept is that thyroid-specific T cells in Graves' disease primarily act as helper (CD4+ Th1) cells.
   - ■ **Histology:** Characterized by **follicular hyperplasia, intracellular colloid droplets, cell scalloping,** a reduction in follicular colloid, and a patchy (multifocal) **lymphocytic infiltration.**

TABLE 13.7B: Causes of hyperthyroidism.

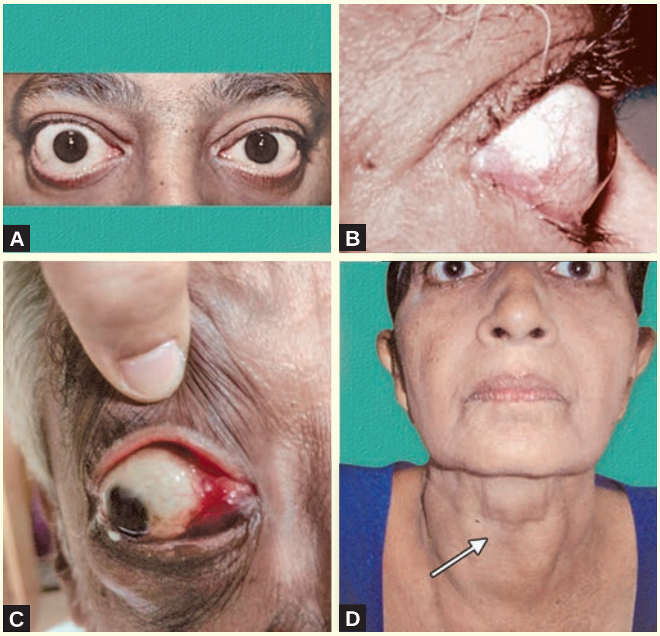
Hyperthyroidism with a normal or high radioiodine uptake
Autoimmune thyroid disease
Graves' disease
Hashitoxicosis
Autonomous thyroid tissue (uptake may be low if recent iodine load led to iodine-induced hyperthyroidism)
Toxic adenoma
Toxic multinodular goiter
TSH-mediated hyperthyroidism
TSH-producing pituitary adenoma
Non-neoplastic TSH-mediated hyperthyroidism
Human chorionic gonadotropin-mediated hyperthyroidism
Hyperemesis gravidarum
Trophoblastic disease
Hyperthyroidism with a near absent radioiodine uptake
Thyroiditis
Subacute granulomatous (de Quervain's) thyroiditis
Painless thyroiditis (silent thyroiditis, lymphocytic thyroiditis)
Postpartum thyroiditis
Amiodarone (also may cause iodine-induced hyperthyroidism)
Radiation thyroiditis
Palpation thyroiditis
Exogenous thyroid hormone intake
Excessive replacement therapy
Intentional suppressive therapy
Factitious hyperthyroidism
Ectopic hyperthyroidism
Struma ovani
Metastatic follicular thyroid cancer

Box 13.5: Thyroid orbitopathy (eye signs) **(Table 13.8** and **Figs. 13.8A to D).**

- An **autoimmune disease** of the retro-ocular tissues occurring in patients with Graves' disease. Although it has often been referred to as Graves' ophthalmopathy, or thyroid eye disease (TED), it is **primarily a disease of the orbit** and is better termed **Graves' orbitopathy**.
- The ophthalmopathy causes **abnormal protrusion of the eyeball (exophthalmos)**.
- **Sympathetic overactivity** may produce the characteristic **wide, staring gaze, and** can also be the reason for **lid lag**.
- It is observed in about **50%** of the patients when first seen. It may precede Graves' disease by many years or may develop even after successful treatment of Graves' disease.
- The volume of both the extraocular muscles and retro-ocular connective tissue is increased due to **fibroblast proliferation**, **inflammation** and the accumulation of **hydrophilic glycosaminoglycans** (GAG), mostly hyaluronic acid.
- **Pathogenesis of orbitopathy:**
  - The main autoantigen is the **thyroid-stimulating hormone receptor (TSHR)**, which is expressed primarily in the thyroid but is also expressed in adipocytes, fibroblasts, and a variety of additional sites.
  - TSHR antibodies and T-cells activate **retro-ocular fibroblast** and **adipocyte TSHR and IGF-1 receptors,** initiating a **retro-orbital inflammatory environment**.
  - GAG secretion by fibroblasts is increased by thyroid-stimulating antibodies and activated T cells (via cytokine secretion), implying that both **B and T cell activation** are integral to this process.
  - The accumulation of hydrophilic GAG in turn leads to **fluid accumulation, muscle swelling**, and an **increase in pressure within the orbit.**
  - These changes, together with retro-ocular adipogenesis, displace the eyeball forward leading to extraocular muscle dysfunction and impaired venous drainage.
- **Symptoms:** There may not be any ocular symptoms, but the patient may be distressed by the appearance. However, the following symptoms can prevail:
  - A gritty or foreign object sensation in the eyes
  - Excessive tearing, often made worse by exposure to cold air, wind, or bright lights
  - Eye or retro-ocular discomfort or pain
  - Blurring of vision
  - Diplopia
  - Color vision desaturation
  - Loss of vision in severe cases
- **Signs**
  - Exophthalmos (proptosis) often asymmetric but can be symmetric
  - Lid lag
  - Lid retraction
  - Periorbital edema
  - Corneal ulcers
  - Chemosis
  - Ophthalmoplegia
  - Visual field defects
  - Papilledema
- **Treatment**
  - **Reversal of hyperthyroidism:**
    - ◆ Rapid amelioration of symptoms, with a **beta-blocker**—atenolol (25–50 mg/day), which has the advantages of single daily dosing and beta-1 selectivity.

TABLE 13.8: Eye signs of thyrotoxicosis.

Eye signs	*Description*
Dalrymple sign	Rim of sclera is seen all around the cornea on looking straightforward
Rosenbach's sign	Fine tremor of the upper eyelids on slight closure of the eye
Joffroy's sign	Lack of wrinkling of the forehead when a patient looks upward
Möbius sign	Lack of convergence on looking to near object
Von Graefe's sign (lid lag)	Lagging of the upper eyelid on looking downward without moving the head
Stellwag's sign	Staring look with infrequent blinking
Vigouroux sign	Eyelid fullness
Grove sign	Resistance to pulling down the retracted upper lid
Ballet sign	Restriction of one or more extraocular muscles
Kocher sign	Staring look (upper sclera visible)
Naffziger's sign	Standing behind, patient's neck is extended and examiner looks from behind along the superior orbital margin of the patient. Eyeball is seen beyond the superior orbital margin in exophthalmos



FIGS. 13.8A TO D: (A and B) Exophthalmos (front and side view); (C) Infiltration of extraocular muscles in hyperthyroidism; (D) Eye signs and enlarged nodular goiter (arrow).

    - Decreasing thyroid hormone synthesis with a **thionamide.** The goal of thionamide therapy in Graves' hyperthyroidism is to attain euthyroid state within 3-8 weeks. **Methimazole** 5–40 mg is the drug of choice used to treat Graves' hyperthyroidism. **Propylthiouracil (PTU)** is preferred during the first trimester of pregnancy, because of the more significant teratogenic effects of methimazole.
    - **Radioiodine Ablation:** Preferred as definitive therapy of hyperthyroidism in nonpregnant patients except in patients with moderate or severe orbitopathy, administered as a capsule of sodium iodine-131 (I-131), concentrated in thyroid tissue. Radioiodine induces extensive tissue damage, resulting in ablation of the thyroid within 6–18 weeks.
    - **Glucocorticoids—**inhibit peripheral T_4 to T_3 conversion and, in patients with Graves' hyperthyroidism, reduce thyroid secretion. They have been used in patients with severe hyperthyroidism and thyroid storm.
    - **Cholestyramine—**dose of 4 g four times daily with methimazole, lowers serum T_4 and T_3 concentrations more rapidly than methimazole alone and may be useful adjunctive therapy.
    - **Surgery—**for a patient with severe hyperthyroidism and a large goiter.
    - Reduction of thyroid hormone synthesis **decreases eyelid retraction and stare**s (if hypothyroidism develops during the course of therapy, more fluid retention can occur and may have an adverse effect on the orbitopathy).
    - For patients with active and moderate-to-severe or sight-threatening orbitopathy, thionamides or surgery are the preferred treatment modalities, as this is usually followed by a fall in serum thyrotropin receptor antibody (TRAb) concentrations, suggesting a waning of autoimmunity.
    - **Radioiodine therapy** leads to the development or worsening of orbitopathy as it is associated with a sustained increase in TRAb, hence **contraindicated**.
    - Patients with active and mild orbitopathy may still be candidates for thionamides, radioiodine, or surgery. If radioiodine is chosen, glucocorticoids should be administered concurrently for those with risk factors for progression.
  - **Smoking cessation:** Increases the incidence of symptomatic Graves' orbitopathy, increases the risk of worsening orbitopathy after radioiodine therapy and also renders patients more refractory to anti-inflammatory therapy.
  - **Local measures: Eye shades, artificial tears, and lubricants** such as methylcellulose or petroleum jelly, raising headend of bed at night, **eyepatching** and **prisms** for diplopia.
  - **Medical**:
    - **Selenium** 100 μg twice daily may improve symptoms in patients with mild Graves' orbitopathy. It has an antioxidant role and also decreases inflammatory activity.
    - **Glucocorticoids** are the **mainstay** of **immunomodulatory therapy** for moderate-to-severe Graves' orbitopathy. For patients with moderate symptoms, a trial of oral (**prednisone**, 30 mg/day for 4 weeks) or IV (**methylprednisolone**, 500 mg once weekly for weeks 1–6, then 250 mg once weekly for weeks 7–12 with cumulative dose 4.5–5 g over 12 weeks) can be tried. For more severe or progressive cases, initial IV therapy is appropriate.
    - **Teprotumumab,** an **IGF-1 receptor inhibitor**, was approved for the treatment of Graves' orbitopathy by the Food and Drug Administration (FDA) in February 2020. It is administered every 3 weeks as an IV infusion (10 mg/kg initial dose, then 20 mg/kg) for a total of eight infusions. Teprotumumab is **contraindicated** during pregnancy.
    - **Mycophenolate mofetil** is under investigation for the treatment of Graves' orbitopathy, either alone or in combination with glucocorticoids.
    - **Tocilizumab** targets IL-6 is being investigated for the treatment of patients with Graves' orbitopathy who are not improving with glucocorticoids.
    - **Rituximab** reported to be as effective as glucocorticoids without the glucocorticoid-related side effects induces a fall in thyrotropin receptor antibody (TRAb) levels and depletion of B cells in the retro-orbital tissues.
  - **Orbital decompression surgery: Indicated in** optic neuropathy caused by enlarged extraocular muscles not responsive to high-dose corticosteroids, severe orbital inflammation, excessive proptosis leading to exposure keratitis, corneal ulceration, or debilitating cosmetic defect, pain relief, and progressive orbitopathy not responding to other measures.
  - **Other surgeries:**
    - Fat decompression surgery, bilateral lateral tarsorrhaphy, surgical recession of Müller's muscle and the levator to correct upper lid retraction.
    - For patients requiring both strabismus surgery and orbital decompression, the **decompression** should be **performed first**, followed by strabismus surgery.

- **Ophthalmopathy and dermatopathy:** Observed in Graves' disease is due to **immunologically mediated** activation of fibroblasts in the **extraocular muscles and skin**. This along with accumulation of **glycosaminoglycans** and **trapping of water causes edema** initially. Later fibroblasts cause fibrosis.
- **Hyperthyroidism may be triggered by viral or bacterial infections**. *E. coli* and *Yersinia enterocolitica* possess cell membrane TSH receptors. The antibodies produced against these micro-organisms can cross-react with the TSH receptors (molecular mimicry).
- **Other mediating mechanisms**: Bystander activation and thyroid cell HLA-antigen expression.

- **Other precipitating causes**:
  - Thyroid injury by radiation and drugs
  - Stress
  - Smoking
  - Sex steroids
  - Pregnancy
  - Fetal microchimerism
  - Iodine and iodine-containing drugs such as amiodarone.
  - Alemtuzumab, a monoclonal antibody against CD52, has been associated with a 10–15% incidence of new-onset Graves' disease.

2. **Treatment-induced hyperthyroidism.**
   Drugs include iodine, amiodarone, iodine-containing contrast media, interferon-alpha, and rarely, lithium.
   - **Iodine-induced hyperthyroidism**
     - It develops following excess intake of iodine in diet or exposure to radiographic contrast media or iodine medication.
     - **Jod-Basedow phenomenon:** In states of iodine deficiency, thyroid nodules can develop, some of which can be autonomous functioning nodules. On supplementation of iodine, there is an increase in production of thyroxine, leading to **thyrotoxicosis**. Usually develops in patients with autonomously functioning thyroid gland (e.g., nodular goiter/Graves' disease). It can also occur in endemic goiter and with iodine. Takes place due to a loss in the negative feedback mechanism of the circulating hormones on the thyroid gland.
     - It is characterized by suppressed serum TSH level with normal levels of circulating thyroid hormone.
     - **Wolff-Chaikoff effect**: Autoregulation by the follicular cells protects the gland from the wide variations in the amount of iodide intake. Sometimes, excess exposure and uptake of iodide by the gland can inhibit organification of iodide, thereby diminishing hormone biosynthesis, resulting in **hypothyroidism or myxedema.**
   - **Amiodarone-induced hyperthyroidism (AIT):** Amiodarone is a class III antiarrhythmic drug. A 200-mg formulation of the drug contains 75 mg iodine. It can also induce hyperthyroidism which can be **(Table 13.9)**.

TABLE 13.9: Amiodarone-induced hyperthyroidism (AIT).

Type I AIT	*Type II AIT*
➢ It develops in patients with pre-existing multinodular goiter or latent Graves' disease. ➢ There is hyperthyroidism with increased synthesis of T_4 and T_3 and is triggered by the high iodine content of amiodarone. ➢ Jod-Basedow effect (refer above) occurs in patients with underlying thyroid disease.	➢ It is not associated with previous thyroid disease. ➢ It is due to a direct cytotoxicity of amiodarone on thyroid follicular cells leading to a destructive thyroiditis with release of T_3 and T_4. ➢ It produces a hyperthyroid phase which may last several weeks to months and may later progress to hypothyroid phase and eventual recovery in most but not all patients.

3. **Thyrotoxicosis factitia**
   - Exogenous hyperthyroidism is due to the **surreptitious ingestion of thyroid hormone**, it is termed as "thyrotoxicosis factitia".
   - Patients are **clinically thyrotoxic** without eye signs of Graves.
   - High doses of thyroxine lead to TSH suppression and causes shrinkage of the thyroid.
   - Find cause or contamination and treat symptomatically.
4. **Toxic multinodular goiter (Plummer's disease)**
   - Result of **diffuse hyperplasia of thyroid follicular cells** whose functional capacity is independent of regulation by TSH.
   - Goiter will be nodular.
   - Constitutes 14% of thyrotoxicosis cases.
   - Commonly occurs in elderly women (>50 years).
   - T_3 (greater), T_4 raised, and TSH undetectable.
5. **Toxic solitary adenoma/nodule**
   - Constitutes <5% of all thyrotoxicosis (hyperthyroidism) cases and the solitary nodule is follicular adenoma.
   - Usually occurs in female >40 years of age.
   - Suspected thyroid nodules merit close attention in the pediatric population because such nodules are much more likely to be malignant in children than they are in adults.

Clinical Features of Thyrotoxicosis (Table 13.10)

Q. IM12.5 Elicit document and present an appropriate history that will establish the diagnosis cause of thyroid dysfunction and its severity.

TABLE 13.10: Clinical features of thyrotoxicosis.

Organ/system involved	***Symptoms/Signs***	
Thyroid	Diffuse or nodular enlargement, warmth	Bruit (due to increased vascularity)
Gastrointestinal system	➢ **Weight loss despite increased appetite** ➢ Vomiting ➢ Abdominal pain ➢ Increased gut motility ➢ Hyperdefecation and diarrhea	➢ Malabsorption ➢ Steatorrhea ➢ Dysphagia due to goiter ➢ Celiac disease is also more prevalent in patients with Graves' disease
Cardiovascular system	➢ Tachycardia ➢ Exertional dyspnea ➢ Palpitations ➢ Hyperdynamic precordium ➢ Pulmonary hypertension ➢ Angina	➢ **Sinus tachycardia, atrial fibrillation** ➢ Wide pulse pressure ➢ Lowering of diastolic blood pressure ➢ Cardiac failure ➢ Cardiomyopathy ➢ Means-Lerman scratch (scratchy midsystolic murmur)
Neuropsychiatric system	➢ Nervousness ➢ **Irritability** ➢ Psychosis ➢ Emotional lability ➢ Fine **tremors** ➢ Agitation ➢ Depression ➢ Inability to concentrate	➢ Insomnia ➢ Hyperreflexia ➢ Cognitive impairments ➢ Poor orientation and immediate recall ➢ Amnesia ➢ Constructional difficulty ➢ Proximal myopathy ➢ Bulbar myopathy ➢ Ill-sustained clonus
Respiratory system	➢ Increased ventilation: hypoxemia and hypercapnia ➢ Respiratory muscle weakness ➢ Decreased lung volume	Large goiter causing tracheal obstruction, exacerbation of asthma, and rise in pulmonary arterial systolic pressure
Metabolic/Endocrine	➢ Increased bone resorption—osteoporosis ➢ Periosteal new bone formation (**thyroid acropachy**)	Dyslipidemia Hyperglycemia
Hematologic	➢ Normocytic normochromic anemia ➢ Graves' hyperthyroidism may be associated with autoimmune hematologic disorders such as immune thrombocytopenia (ITP) and pernicious anemia	Maybe prothrombotic, excess thyroid hormone was associated with a rise in prothrombotic factors, including factors VIII, IX, fibrinogen, von Willebrand factor, and plasminogen activator inhibitor-1
Skin/integumentary system	➢ Soft, warm, moist, and smooth skin due to decrease in keratin layer ➢ Increased sweating ➢ Pruritus, hives ➢ Onycholysis and softening of nails ➢ Palmar erythema ➢ Spider naevi ➢ Hyperpigmentation	➢ Vitiligo ➢ Alopecia areata ➢ Clubbing ➢ Infiltrative dermopathy occurs only in patients with Graves' hyperthyroidism. The most common site is the skin overlying the shins, where it presents as raised, hyperpigmented, violaceous, orange-peel-textured papules **[Pretibial Myxedema (Box 13.6)]**
Urinary	Urinary frequency	Nocturia
Sex hormones	**Women:** Oligomenorrhea, amenorrhea, and anovulatory infertility	**Men:** Gynecomastia, reduced libido, erectile dysfunction, and abnormal/decreased spermatogenesis
General	**Heat intolerance:** Fatigue, gynecomastia	➢ Apathy, thirst ➢ Thymic enlargement in Graves' disease.
Eyes (classically seen in Graves' disease)	➢ Stare ➢ Lid lag ➢ **Exophthalmos** ➢ Proptosis	➢ Extraocular diplopia ➢ Exposure keratitis ➢ Lagophthalmos

Note: Bold words indicate symptoms of greater discriminant value.

- **Classic symptoms** include heat intolerance, tremor, palpitations, anxiety, weight loss, increased appetite increased frequency of bowel movements, and shortness of breath.
- **Elderly** patients present with anorexia, apathy, fatigue, weight loss, and dominant cardiovascular and myopathic features **(apathetic hyperthyroidism).**
- **Younger** patients present predominantly with neurological manifestations.
- **Children** present with excessive height or excessive growth rate, or with behavioral problems (e.g., hyperactivity), and weight gain rather than loss.

Box 13.7 lists the other disorders associated with Graves' disease.

Subclinical hyperthyroidism

- **Clinical manifestations (Box 13.8).**
- **Laboratory findings:** Serum levels of free T_4 and T_3 are within normal limits. Serum TSH levels is subnormal (<0.5 mU/L).

Box 13.6: Pretibial myxedema (infiltrative dermopathy).

Q. Write short essay/notes on pretibial myxedema.

- Formerly used to occur in 5% of patients with only Graves' disease and 15% of patients with both Graves' disease and ophthalmopathy. However, the **incidence has declined** due to early diagnosis and treatment of Graves' disease.
- Characterized by **bilateral, asymmetric, nonpitting, scaly thickening, and induration of the skin.**
- Lesion may be **violaceous or slightly pigmented** (yellow-brown) and often have a peau d'orange appearance.
- The most frequent location is over the **lower limbs**, especially the pretibial areas or the dorsum of the foot. Rarely, the fingers and hands, elbows, arms, or face are affected (**Fig. 13.9**).
- Rarely, lesions progress to involve the legs, feet, or hands completely, resulting in a form reminiscent of elephantiasis.
- Occurs due to **deposition of glycosaminoglycans** especially hyaluronic acid, secreted by fibroblasts under the stimulation of local cytokines arising from a lymphocytic infiltration.
- **Treatment of pretibial myxedema**
  - Some patients do not seek treatment as they are asymptomatic.
  - **Indications:** Pruritus, local discomfort, the unsightly appearance of the lesions, or progression of lesions.
  - **Nonpharmacologic** includes minimizing risk factors, such as avoiding tobacco, reducing weight, normalizing thyroid function and in severe cases, physiotherapy. Normalization of thyroid function does not necessarily improve pretibial myxedema.
  - **Pharmacologic**
    - Topical 0.025% **fluocinolone acetonide** under plastic wrap.
    - **Intralesional corticosteroids** if there is no improvement with topical treatment after 4–12 weeks, using **triamcinolone acetate** dose calculated according to 8 mg per 2 cm—diameter circle area at each session, but the total dose was not >100 mg at each session in a patient.
    - **Pentoxifylline** may be helpful in resistant cases.

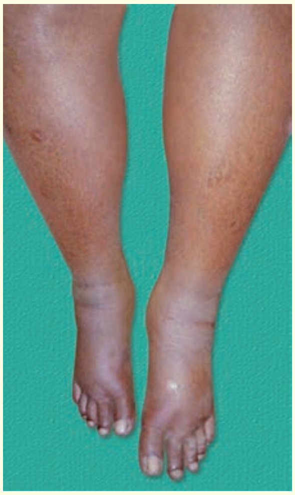


FIG. 13.9: Nonpitting pedal edema-myxedema.

Box 13.7: Other disorders associated with Graves' disease.

- **Autoimmune disorders**
  - **Endocrine:** Addison's disease, type 1 diabetes mellitus (DM), Hashimoto's thyroiditis, primary gonadal failure, hypophysitis
  - **Nonendocrine:** Celiac disease, pernicious anemia, myasthenia gravis, immune thrombocytopenic purpura, rheumatoid arthritis, vitiligo, and alopecia areata
- **Others:** Hypokalemic periodic paralysis and mitral valve prolapse

Box 13.8: Clinical manifestations of subclinical hyperthyroidism.

Bone disease

- Decreased bone density, especially in postmenopausal women
- Increased fracture risk
- Biochemical markers of increased bone resorption
  - Increased urinary pyridinoline and deoxypyridinoline excretion
  - Increased urinary hydroxyproline excretion

Heart disease

- Increased incidence of atrial fibrillation
- Increased heart rate and incidence of atrial premature beats
- Increased cardiac contractility
- Increased left ventricular mass index and septal and posterior wall thickness

Laboratory abnormalities

- Decrease in serum total and low-density lipoprotein low-density lipoprotein (LDL) cholesterol concentrations
- Increased serum concentrations of hepatic enzymes and creatine kinase
- Increased serum concentration of sex hormone-binding globulin (SHBG)

Other

- Decreased time asleep at night
- Improved mood

Investigations of Graves' Disease

- **TSH levels: Very low or undetectable**. This is performed as the primary test and normal level excludes thyrotoxicosis.
- **Serum T_3 and T_4 levels:** Raised in most cases. T_3 thyrotoxicosis is associated with raised T_3 levels and normal T_4 level.
- **Absence of TSH response** following intravenous **TRH**.
- **^{131}I uptake by the thyroid gland:** It may be increased but not necessary to perform in most of the patients.
- **TSH receptor antibody (TRAb):** Present in most cases.
- Few patients may show minor LFT abnormalities, mild hypercalcemia, and glycosuria.

Q. IM12.13 Describe the pharmacology, indications, adverse reaction, interactions of thyroxine and antithyroid drugs.

Q. IM12.15 Describe and discuss the indications of thionamide therapy, radioiodine therapy and surgery in the management of thyrotoxicosis.

Management of Hyperthyroidism of Graves' Disease

- The therapeutic approach to Graves' hyperthyroidism consists of both **rapid amelioration** of symptoms with a beta-blocker and measures aimed at **decreasing thyroid hormone synthesis**: the administration of a thionamide, radioiodine ablation, or surgery.
- **Symptom control:** Beta-blocker, **Propranolol** (drug of choice) in the dose of 20–40 mg 6 hourly or **Atenolol** 25–50 mg/day to reduce symptoms for immediate relief **due to sympathetic overactivity** such as anxiety, palpitation, increased bowel activity, lid retraction, finger tremors.
- **Decrease thyroid hormone synthesis:** There are three treatment options for Graves' disease. All three options are effective, but all three options have significant side effects. There is no consensus as to the "best" treatment: (i) Antithyroid drugs (thionamides), (ii) Radioiodine and (iii) Surgery.

1. **Antithyroid drugs (ATD)** may be used initially to control hyperthyroidism (in addition to beta-blockers) prior to definitive therapy with radioiodine or surgery; they may be prescribed for 1–2 years to attain a remission, or may be used long-term.
   - **Indications:** Primary therapy in **pregnancy**, in **children** and **adolescents** and **severe Graves' disease with eye changes**.
   - The drugs include: **Thionamides: Methimazole**, **Propylthiouracil, and Carbimazole**
   - **Mechanism of action:** Inhibit the function of **thyroid peroxidase (TPO) enzyme** and prevent binding of iodine to tyrosine (prevents iodination and organification).
     - **Methimazoleis the primary drug used to treat hyperthyroidism. Dose:**
       - ☐ Free T_4 1–1.5 times upper limit of normal: begin treatment with 5–10 mg once daily.
       - ☐ Free T_4 1.5–2 times upper limit of normal: begin treatment with 10–20 mg once daily.
       - ☐ Free T_4 2–3 times upper limit of normal: begin treatment on 20–40 mg daily in divided doses.
       - ☐ The dose is tapered to maintenance levels (5–10 mg/day) as the patient improves.
     - **Propylthiouracil:** Preferred during the first trimester of pregnancy. **Dose:** 300 mg daily in 3 equally divided doses; 400 mg daily in patients with severe hyperthyroidism and/or very large goiters; usual maintenance: 100–150 mg daily in 3 divided doses.
     - **Carbimazole:** It has additional immunosuppressive action.
       - ☐ **Dose:** Initially 20–60 mg daily given in 2–3 divided doses and maintenance 5–15 mg daily or alternatively 20–60 mg daily.
       - ☐ **Total duration of treatment:** 18–24 months.
       - ☐ **Adverse effects:** Rashes, urticaria, fever, arthralgia, blood dyscrasias **(agranulocytosis),** hepatotoxicity, aplasia cutis in neonates.
   - **Advantages:**
     - No surgical risk, scar, or chances of injury to parathyroid or recurrent laryngeal nerve.
     - Hypothyroidism, if induced, is reversible.
     - Can be used even in children and young adults.
   - **Disadvantages:**
     - Prolonged (often lifelong) treatment is needed and relapse rate is high.
     - Not practicable in uncooperative patient.
2. **Radioiodine ablation:** Preferred as **definitive therapy** of hyperthyroidism in nonpregnant patients except in patients with moderate or severe orbitopathy and chronic smokers. Administered as a capsule I^{131}, induces extensive tissue damage by emitting gamma-radiation from within the follicles, resulting in ablation of the thyroid within 6–18 weeks.
   - **Dose:** 185–555 MBq
   - **Indications:** (i) Patients **above 40 years of age,** (ii) young patients with a short lifespan due to some other reason, and (iii) young individuals who are sterilized.
   - **Complications: Hypothyroidism**, infertility, and secondary cancers.
3. **Surgery: Subtotal thyroidectomy** is the **treatment of choice**. Surgical treatment is reserved for multinodular goiter (MNG) with following features:
   - Severe hyperthyroidism in children.
   - Pregnant women who cannot tolerate antithyroid drugs.
   - Large goiters with severe ophthalmopathy or with pressure symptoms.
   - Patients who require quick normalization of thyroid function
   - **Preparation for thyroidectomy:** It includes pretreatment with propranolol or atenolol, methimazole 5–40 mg depending on severity and potassium iodide (to decrease vascularity and make the gland firm) 8 mg iodide per drop, 5–7 drops three times daily for 2 weeks before surgery.
   - **Postoperative complications:** Hypothyroidism, hypoparathyroidism, hypocalcemia, and damage to recurrent laryngeal nerve.

- **Adjunctive therapies:**
  - **Oral radiocontrast agents: Sodium ipodate** and **iopanoic acid** are potent inhibitors of the peripheral conversion of T_4 to T_3. **Dose**: A dose of 500–1,000 mg/day in combination with methimazole can rapidly ameliorate severe hyperthyroidism and can also be used to prepare a hyperthyroid patient for early surgery.
  - **Iodine elixirs:** Up to 10 drops of **saturated solution of potassium iodide** [SSKI, 50 mg iodide per drop (0.05 mL)] daily for 7–10 days is used perioperatively to reduce gland vascularity.
  - **Glucocorticoids** inhibit peripheral T_4 to T_3 conversion and in patients with Graves' hyperthyroidism reduce thyroid secretion (**Table 13.11**).
  - **Cholestyramine**, given in a dose of 4 g four times daily with methimazole, lowers serum T_4 and T_3 concentrations more rapidly than methimazole alone.
  - **Potassium perchlorate:** It reduces uptake of iodine. It is more toxic and produces red cell aplasia. It is used only as temporary measure in iodine-induced thyrotoxicosis or when other therapy is not acceptable.
  - **Lithium:** Blocks thyroid hormone release, but its use has been limited by its toxicity.
  - **Rituximab:** May induce a sustained remission in patients with Graves' disease and induces low TSH-receptor antibodies (TRAb) levels, but its cost and side effects limit its utility.
- **Skeletal health:** Advised to **ingest 1,200–1,500 mg elemental calcium** daily through diet or supplements.

TABLE 13.11: Treatment of Graves' hyperthyroidism.

Therapy	*Advantages*	*Disadvantages*
Thionamides	Chance of permanent remission Some patients avoid permanent hypothyroidism Lower initial cost	➢ Minor side effects—rash, hives, arthralgias, transient granulocytopenia, gastrointestinal symptoms ➢ Major side effects—agranulocytosis, vasculitis (lupus-like syndrome), hepatitis ➢ Risk of fetal goiter, hypothyroidism, and birth defects if pregnant ➢ Requires more frequent monitoring
Radioiodine	Permanent resolution of hyperthyroidism	➢ Permanent hypothyroidism ➢ Patient must take radiation precautions for several days after treatment, avoiding contact with young children and pregnant women ➢ Development or worsening of Graves ophthalmopathy ➢ Rare radiation thyroiditis ➢ Patient concerns about long-term oncogenic effects of radiation
Surgery	Rapid, permanent cure of hyperthyroidism	➢ Permanent hypothyroidism ➢ Risks for iatrogenic hypoparathyroidism and recurrent laryngeal nerve damage ➢ Risks associated with general anesthesia ➢ High cost

Approach for the hyperthyroidism is presented in **Flowchart 13.3**.

FLOWCHART 13.3: Approach to diagnosis in hyperthyroidism.

Hyperthyroid Crisis/Thyrotoxic Crisis/Thyroid Storm

Q. Write short essay/note on hyperthyroid crisis/thyrotoxic crisis/thyroid storm/thyroid crisis.

It is a rare **life-threatening** medical emergency that develops as **complication of thyrotoxicosis** which is associated with a mortality of 10–30%.

Causes of Hyperthyroid Crisis

- Thyroid storm can develop in patients with longstanding untreated hyperthyroidism (Graves' disease, toxic multinodular goiter, and solitary toxic adenoma), it is often precipitated by an acute event:
  - **Severe infections** in a patient with previously undetected or inadequately treated hyperthyroidism/thyrotoxicosis.
  - **Following surgery:** May develop **following subtotal thyroidectomy** in an ill-prepared patient or some other surgery in an undetected hyperthyroidism/thyrotoxicosis.
  - **Following radiotherapy:** May occur within a few days of ^{131}I therapy in an inadequately prepared patient. This is because of a transient rise in serum thyroid hormone levels caused due to acute damage by irradiation.
  - **Other precipitating factors:**
    - Cerebrovascular accidents
    - Diabetic ketoacidosis
    - Acute coronary syndrome
    - Use of iodine contrast agent
    - Acute iodine load
    - Parturition
    - Sudden withdrawal of antithyroid medications
    - Stress
    - Major trauma.
- It is unclear why certain factors result in the development of thyroid storm. Hypotheses include a **rapid rate of increase** in **serum thyroid hormone** levels, **increased responsiveness to catecholamines**, or **enhanced cellular responses to thyroid hormone**. One study found that while the total T_4 and T_3 levels were similar to those seen in uncomplicated patients, the free T_4 and free T_3 concentrations were higher in patients with thyroid storm.

Clinical Features

- The clinical manifestations are due to **marked hypermetabolism** and **excessive adrenergic response.**
- **Hyperpyrexia** from 104°F to 106°F is common and is associated with flushing and sweating.
- **Marked tachycardia** rates that can exceed 140 beats/min, often with **atrial fibrillation** and high pulse pressure, hypotension, occasionally congestive heart failure occurs. A fatal outcome is associated with heart failure and shock.
- **Central nervous system symptoms** include marked **agitation, restlessness, delirium**, psychosis, stupor, and coma.
- **Gastrointestinal symptoms** include nausea, vomiting, diarrhea, abdominal pain, and hepatic failure with jaundice.
- **Physical examination** may reveal goiter, ophthalmopathy (in the presence of Graves' disease), lid lag, hand tremor, and warm and moist skin.

Laboratory Findings

- **Low TSH** and **high free T_4 and/or T_3** concentrations
- Nonspecific laboratory findings may include—mild hyperglycemia secondary to a catecholamine-induced inhibition of insulin release and increased glycogenolysis, mild hypercalcemia due to hemoconcentration and enhanced bone resorption, abnormal liver function tests, leukocytosis, or leukopenia.

Treatment of Hyperthyroid Crisis

- Patients should be admitted in ICU, **rehydrated,** and given **antibiotics** if there is infection.
- **Control hyperthermia:** Aggressively by external cooling. **Acetaminophen should be used instead of aspirin** since the latter can increase serum free T_4 and T_3 concentrations by interfering with their protein binding.
- **Propranolol:** Either orally (60–80 mg every 4–6 hours) or intravenously (1–5 mg 4 times daily). It also blocks peripheral conversion of T_4 to T_3. The Japanese guidelines recommend **esmolol** over **propranolol** because of increased mortality in patients with congestive heart failure treated with propranolol. In patients with reactive airways disease, cardioselective beta-blockers such as **metoprolol** or **atenolol** could be considered.
- **Propylthiouracil** 200 mg orally every 4 hours (preferred as it decreases T_4 to T_3 conversion) or **methimazole** (20 mg orally every 4–6 hours) **or carbimazole** (inhibit the synthesis of new thyroid hormone) 15–30 mg stat followed by 15 mg TID. In an unconscious or uncooperative patient, carbimazole can be administered rectally with good effect.

- **Lugol's iodine:** 10 drops TID about 1 hour after the first dose of thionamide.
- **Sodium iopodate:** 500 mg/day orally will restore serum T_3 levels to normal within 48–72 hours. This is a radiographic contrast medium which inhibits the release of thyroid hormones and also reduces the conversion of T_4 to T_3. Hence, more effective than potassium iodide or Lugol's solution.
- **IV hydrocortisone:** 100 mg every 8 hours.
- **Bile acid sequestrant, cholestyramine:** 4 g orally QID to reduce enterohepatic recycling of thyroid hormones.
- **Benzodiazepines:** For agitation.
- **Digoxin:** To control cardiac failure and atrial fibrillation (AF).
- **Plasmapheresis** has been tried when traditional therapy has not been successful, it removes cytokines, antibodies, and thyroid hormones from plasma.
- **Lithium** has also been given to acutely block the release of thyroid hormone. However, its renal and neurologic toxicity limit its utility.

Hypothyroidism

Q. Describe the etiology, clinical features, diagnosis, and management of primary hypothyroidism/spontaneous atrophic hypothyroidism.

- Hypothyroidism is a **clinical syndrome resulting from a deficiency of thyroid hormones.** It results in a generalized slowing down of metabolic processes.
- **Infants and children:** Hypothyroidism results in marked **slowing of growth and development** with serious permanent consequences including **mental retardation**, when it occurs in infancy **(cretinism)**.
- **Adults:** Hypothyroidism causes a **generalized decrease in metabolism** with slowed heart rate, diminished oxygen consumption, and deposition of glycosaminoglycans in intracellular spaces, particularly in skin and muscle, producing in extreme cases the clinical picture of **myxedema**.

Classification and Etiology (Table 13.12)

TABLE 13.12: Etiology of hypothyroidism.

Primary	*Secondary*	*Tertiary*
➢ Dyshormonogenesis **(Pendred syndrome)** ➢ Hashimoto's thyroiditis (chronic autoimmune thyroiditis) ➢ Radioactive iodine therapy ➢ External neck irradiation ➢ Subtotal thyroidectomy for Graves' disease, nodular goiter, or thyroid cancer ➢ Excessive iodide intake (radiocontrast dyes) ➢ Subacute thyroiditis (usually transient) ➢ Postpartum thyroiditis ➢ Iodide deficiency ➢ Drugs: Lithium, interferon-alfa, amiodarone, propylthiouracil (PTU), methimazole, ethionamide, ipilimumab, pembrolizumab, and nivolumab ➢ Environmental exposures: polybrominated diphenyl ethers (fire retardant) ➢ Infiltrative diseases: fibrous thyroiditis (Reidel's thyroiditis), hemochromatosis, scleroderma, leukemia, and cystinosis	➢ Hypopituitarism due to pituitary adenoma ➢ Pituitary ablative therapy ➢ Pituitary destruction ➢ Sheehan syndrome ➢ Trauma ➢ Hypophysitis ➢ Nonpituitary tumors such as craniopharyngiomas ➢ Infiltrative diseases ➢ Inactivating mutations in the gene for either TSH or the TSH receptor	➢ Hypothalamic dysfunction (rare) ➢ Mutations in the gene for the TRH receptor ➢ Hypothalamic damage results from – Tumors – Trauma – Radiation therapy – Infiltrative diseases ➢ Rarely peripheral resistance to the action of thyroid hormone

Q. Write short essay/note on causes of hypothyroidism and treatment.

- ***Primary hypothyroidism*:** Due **intrinsic disorder of the thyroid gland**. Accounts for over 95% of cases of hypothyroidism. There are **two** degrees of primary hypothyroidism:
  1. **Subclinical hypothyroidism**, defined as a **high serum TSH** concentration in the presence of **normal serum free T_4 and T_3** concentrations.
  2. **Overt hypothyroidism**, defined as a **high serum TSH** concentration in the presence of a **low serum free T_4** concentration.
- ***Central hypothyroidism*:** It is rare and is caused due to **failure of TSH and TRH production** due to disease of anterior pituitary (**secondary hypothyroidism**) or hypothalamus (**tertiary hypothyroidism**).
- ***Hashimoto's thyroiditis (chronic autoimmune thyroiditis)***
  - **Most common cause** of primary hypothyroidism in iodine sufficient areas of the world.
  - Organ-specific **autoimmune disorder** of thyroid characterized gradual thyroid failure with or without goiter formation by lymphoid infiltration of thyroid leading to apoptosis, fibrosis, and atrophy.

  - The two major forms of Hashimoto's thyroiditis are **goitrous autoimmune thyroiditis** and **atrophic autoimmune thyroiditis** (often called **primary myxedema**), with the common pathologic feature being lymphocytic infiltration, and follicular destruction.
  - Patients have **TRAb** that block the effects of endogenous TSH, antibodies to TPO and thyroglobulin.
  - The cause of Hashimoto's thyroiditis is thought to be a combination of **genetic susceptibility** and **environmental factors**.
  - Several mechanisms have been proposed for the pathogenesis of Hashimoto's thyroiditis. These include **molecular mimicry** and **bystander activation** including the involvement of thyroid cell expression of HLAs and activation of thyroid cell apoptosis by a Fas ligand-Fas interaction.
  - It may be observed in **some patients of Graves' disease** treated with antithyroid drugs 10–20 years earlier.
  - Patients have **high-risk of** developing **other autoimmune disorders** such as type 1 diabetes mellitus, pernicious anemia and Addison's disease.
- ***Postpartum thyroiditis***
  - It is a **destructive thyroiditis** induced by an **autoimmune mechanism** within **1 year of parturition**.
  - It may produce **transient hyperthyroidism** alone, **transient hypothyroidism** alone or the **two sequentially** and then **recovery.**
  - Thyroid biopsies in women with postpartum thyroiditis show **lymphocytic infiltration**, with occasional **germinal centers**, and **disruption and collapse of thyroid follicles** (lymphocytic thyroiditis).
  - **Laboratory assessment** of thyroid function should be performed at **3 and 6 months postpartum** in women at high-risk for developing postpartum thyroiditis, including women with **type 1 diabetes mellitus**, a history of **postpartum thyroiditis after a previous pregnancy** and **history of high serum antithyroid peroxidase antibody concentrations** prior to pregnancy.

Clinical Features (Table 13.13)

Q. Write short essay/note on clinical features of hypothyroidism.

- Depends on the duration and severity of the hypothyroidism.
- **Consequence of prolonged hypothyroidism:**
  - **Infiltration of many body tissues** by the mucopolysaccharides, hyaluronic acid and chondroitin sulfate.
  - **Infiltration of the dermis** produces nonpitting edema (myxedema).

TABLE 13.13: Clinical features of hypothyroidism.

System involved	*Symptoms/signs*	
General	Lethargy, somnolence, **weight gain, goiter (iodine deficiency, Hashimoto's thyroiditis)**	**Cold intolerance**, hoarse voice, pallor, cognitive dysfunction
Thyroid	Enlargement of the gland	
Gastrointestinal	Reduced appetite, constipation, decreased taste, gastric atrophy, celiac disease	Ileus, macroglossia, nonalcoholic fatty liver disease, ascites
Cardiorespiratory	Angina, **bradycardia, diastolic hypertension**, cardiac failure, **pericardial effusion**, pleural effusion, dyslipidemia	Hyperhomocysteinemia, fatigue, shortness of breath on exertion, rhinitis, hypoventilation, reduced pulmonary responses to hypoxia and hypercapnia
Neuromuscular	Aches and pains, muscle stiffness, delayed relaxation of tendon reflexes **(Woltman's sign)***, carpal tunnel syndrome, **depression**, psychosis	Cerebellar **ataxia**, deafness, myotonia, proximal myopathy, pseudohypertrophy of muscles, Hashimoto encephalopathy
Skin	➢ **Myxedema** (nonpitting edema of the skin of hands, feet and eyelids) ➢ Dry flaky skin and hair alopecia ➢ Brittle nails vitiligo	➢ Purplish lips, malar flush, carotenemia, erythema ab igne, xanthelasmas ➢ Madarosis (thinning of lateral one-third of eyebrows)
Reproductive	**Pubertal delay, menorrhagia**, infertility	Galactorrhea (hyperprolactinemia), impotence
Hematological	Macrocytosis, normochromic normocytic hypoproliferative anemia	Hypothyroidism associated hypocoagulable state
Renal	Impaired GFR, renal dysfunction, raised creatinine	
Miscellaneous	➢ Obstructive sleep apnea: Mostly due to macroglossia ➢ Hyponatremia	

Note: Bold words indicate symptoms of greater discriminant value. * Woltman's sign (hung up ankle jerk) is due to decreased myosin ATPase activity and decreased rate of reaccumulation of calcium in the sarcoplasmic reticulum.

  - The term myxedema refers to the **accumulation of mucopolysaccharides in the subcutaneous tissues**. It is most marked in the skin of the hands, feet, and eyelids.
  - **Myxedema facies:** It is a **peculiar facial appearance** characterized by:
    - Striking **periorbital puffiness** (due to myxedema)
    - Scanty eyebrows
    - **Facial pallor** (due to vasoconstriction and anemia), or a **lemon-yellow tint to the skin** (due to **carotenemia** produced by reduced conversion of carotene to vitamin A)
    - Purplish lips and malar flush.
- **Most cases** of hypothyroidism are **not clinically obvious** and should be kept in mind when individuals complain of non-specific symptoms such as tiredness, weight gain, depression or carpal tunnel syndrome.
- Many cases are diagnosed on biochemical screening.

Investigations of Primary Hypothyroidism (Flowchart 13.4)

Majority of hypothyroidism results from an intrinsic disorder of the thyroid gland (primary hypothyroidism).

- **Serum TSH:** It is the investigation of choice. **High** TSH level **confirms primary hypothyroidism.**
- **Serum T_4 levels: Low** level confirms the hypothyroid state.

[T_4: Free T_4 (tetrahydrothyronine); TPOAb: Thyroid peroxidase antibodies; TSH: Thyroid-stimulating hormone]

- **Thyroid and other organ-specific antibodies** may be found.
- **Other abnormalities:**
  - **Increased serum aspartate transferase** from muscle and/or liver
  - Increased serum lactate dehydrogenase (LDH) and **creatine kinase** (CK): With associated myopathy
  - **Hypercholesterolemia and hypertriglyceridemia**
  - **Hyponatremia:** Due to an increase in ADH and impaired free water clearance.
  - **Anemia:** Usually normochromic and normocytic
- **Electrocardiogram (ECG):** Demonstrates sinus bradycardia, low voltage QRS complexes, and ST segment and T wave abnormalities.
- **Chest radiograph:** May reveal enlarged cardiac shadow.

Q. IM12.13 Describe the pharmacology, indications, adverse reaction, interactions of thyroxine.

Treatment of Hypothyroidism

- Hypothyroidism is treated with **T_4**.
- Replacement therapy with **levothyroxine sodium** is given for life as a once daily dosage **(1.6–2.3 µg/kg/day)**.
- **Initial dose***:* It depends upon the severity of the deficiency as well as on the age and fitness of the patient.
  - **For young healthy patients**—1.6 µg/kg/day.
  - **For older patients or those with coronary heart disease**—25–50 µg/day

- **Timing:** Should be taken on an empty stomach with water, ideally 1 hour before breakfast.
- The patient with symptomatic improvement should be re-evaluated with serum TSH measured in 4–6 weeks. If the TSH remains above the reference range, the dose of T_4 can be **increased by 12–25 µg/day in older patients** and in younger patients, it can be increased by a higher dose. The patient will require a repeat TSH measurement in 6 weeks.
- **For patients with heart disease:** 12.5–25 µg/day and increase by 12.5–25 µg/day, if needed, at 6–8 weeks intervals. Few patients with ischemic heart disease may develop angina or worsen with therapy. They require β-blockers, vasodilators or coronary artery bypass graft (CABG) or angioplasty.
- **Dosage adjustments**
  - **Age:** In elderly start with half dose.
  - **Severity and duration of hypothyroidism:** Increase the dose in severe cases
  - **Weight:** 0.5 µg/kg/day increase up to 3.0 µg/kg/day
  - **Malabsorption:** Requires increased dose
  - **Concomitant drug therapy:** Thyroxine only to be taken on empty stomach
  - **Pregnancy:** 25–50% increase in dose, safe in lactating mother
  - **Presence of cardiac disease:** Start low dose or alternate day treatment.
- **Monitoring**
  - **Goal:** It is to **normalize TSH level** regardless of cause of hypothyroidism and to **restore T_4 within the normal range**.
  - **Adequacy of replacement: Assessed clinically** and by **thyroid function tests** after 6 weeks on a steady dose.
  - Complete suppression of TSH should be avoided because it may cause atrial fibrillation and osteoporosis.
  - Lifelong therapy is needed.

Adverse Reactions of Thyroxine

Angina pectoris, tachycardia, palpitations arrhythmia, myocardial infarction, atrial fibrillation, anxiety, weight loss, decreased bone mineral density.

Myxedema Coma

Q. Write short essay on clinical features and management of myxedema coma and myxedema madness.

- Myxedema coma is a **very rare and life-threatening medical emergency** with a high mortality rate that develops as a **complication of severe hypothyroidism (Table 13.14)**.
- The **hallmarks** of myxedema coma are **decreased mentation** and **hypothermia.**
- Other features are bradycardia, hyponatremia, hypoglycemia, hypotension, puffiness of the hands and face, puffy nose, swollen lips, enlarged tongue, hypoventilation, and features of the precipitating cause/illness.
- **Epidemiology and precipitating factors:**
  - It can occur as the culmination of severe longstanding hypothyroidism with **older women** being most affected.
  - It can be precipitated by an acute event in a poorly controlled hypothyroid patient, such as infection, myocardial infarction, hypothermia, surgery, drugs (amiodarone, β-blockers, diuretics, anesthetic agents, barbiturates, lithium, narcotics, and phenothiazines), cardiac failure, hypoxia, hyponatremia, and hypercapnia.
- **Warning signs:** Presence of cool pale skin (due to **hypothermia—**body temperature may be as low as 25°C), absence of mild diastolic hypertension, and altered sensorium.
- **Laboratory findings**
  - Serum **free T_4 is low**, **serum TSH** is usually **high** but sometimes only slightly elevated.
  - Serum **cortisol**, maybe low in patients with central hypothyroidism with associated hypopituitarism and secondary adrenal insufficiency.
  - **Serum creatine phosphokinase** mostly markedly raised.
  - **Hyponatremia**

TABLE 13.14: Management of myxedema coma.

Treatment must be started before biochemical confirmation of the diagnosis.

Abnormality	***Treatment***
Hypothyroidism	➢ Initial intravenous dose of 200–400 µg T_4, followed by daily IV dose of 50–100 µg until oral dose is possible. Total serum T_4 should increase by 2–4 µg/dL ➢ Intravenous (IV) T_3, initially 5–20 µg, followed by 2.5–10 µg every 8 hours
Hypocortisolemia	IV hydrocortisone 100 mg every 8 hours
Hypoventilation	Intubation and mechanical ventilation
Hypothermia	➢ Gentle warming of patient with blankets (passive rewarming) ➢ No active rewarming as it increases the risk for vasodilation and further hypotension
Hyponatremia	Mild fluid restriction, 3% saline
Hypotension	Cautious volume expansion with crystalloid or whole blood and vasopressors
Hypoglycemia	Glucose administration
Precipitating event	Identification and elimination by specific treatment (liberal use of empirical antibiotics)
Other measures	Monitor cardiac output and pressures Whenever needed, cautious use of intravenous fluids, high-flow oxygen or assisted ventilation

Myxedema Madness

- Patient presents with **hypothermia** and neuropsychiatric manifestations.
- **Neuropsychiatric manifestations:** Include:
  - Depression is common in hypothyroidism.
  - Rarely, elderly patient with severe hypothyroidism may become **frankly demented, psychotic, confused, disoriented,** sometimes with **striking delusions and hallucinations**.
- It may develop shortly after starting T_4 replacement.
- **Laboratory findings:**
  - Hypoglycemia and hyponatremia, increased CO_2, decreased WBC count and Hct, increased CPK.
  - Reduced ECG voltage, blood gases often reveal respiratory acidosis, hypoxia and hypercapnia.
  - **EEG**: Slow waves with decreased amplitude, triphasic waves may be present.
  - **CSF analysis**: Elevated protein levels (<100 mg/dL).

Sick Euthyroid Syndrome/Nonthyroid Illness State (NTIS)

Q. Write a short note on sick euthyroid syndrome.

- Nonthyroidal illness influences thyroid hormone production and action at multiple levels, including H-P-T axis, thyroid hormone transport, and metabolism.
- Changes in thyroid function in the setting of **systemic illness, surgery, or fasting not caused by primary thyroid or pituitary dysfunction** are referred to as the nonthyroidal illness syndrome (also called "sick euthyroid syndrome"). Also called "**low-T_3 syndrome**", due to the most common abnormality, a decreased level of serum total T_3.
- Measurement of serum T_4 concentration can be normal, low or elevated.
- Serum TSH, is usually normal but can be influenced by nonthyroidal illness.
- Conditions associated with euthyroid sick syndrome include **malnutrition, HIV, anorexia nervosa, trauma, myocardial infarction, chronic renal failure, diabetic ketoacidosis, cirrhosis, and sepsis**.
- Treatment with thyroxine is not recommended.

Subclinical Thyroid Diseases

Q. Write a short note on subclinical hypothyroidism.

Subclinical Hypothyroidism

- **Subclinical hypothyroidism is defined as an increased serum TSH in the presence of a normal serum free T_4.**
- Prevalent in women and elderly persons.
- Common causes of subclinical hypothyroidism (**Box 13.9**)

Clinical consequences

- Progression to **overt hypothyroidism** (2–4% yearly)
- Risk of **CV disease** especially when TSH >10 mU/L: Diastolic dysfunction, diastolic hypertension, increase in LDL-C, increased hsCRP, alteration in coagulation parameters, and endothelial dysfunction
- **Decreased fertility**
- **Nonalcoholic fatty liver disease (NAFLD)**
- Neuropsychiatric manifestations and increased risk for **Alzheimer disease.**

Indication for treatment with levothyroxine:

- Patients with serum TSH >10.0 mU/L
- Patients <65–70 years, asymptomatic with TSH ≥7 mU/L
- Patients <65–70 years, symptomatic with TSH from *upper limit of normal* to 6.9 mU/L.
- Patients who are infertile, ovulatory dysfunction or planning for pregnancy
- Symptoms or signs of hypothyroidism
- Goiter
- High serum anti-TPO antibodies
- High vascular risk including ischemic heart disease, diabetes, dyslipidemia

Box 13.9: Common causes of subclinical hypothyroidism.

- Iatrogenic
- Hashimoto's thyroiditis
- Postpartum thyroiditis, painless thyroiditis
- Thyroid infiltration (amyloidosis, sarcoidosis, hemochromatosis, etc.)
- Medications: Amiodarone, lithium, interferon, and sorafenib
- Partial thyroidectomy
- Head and neck radiation

Box 13.10: Causes of subclinical hyperthyroidism.

- Iatrogenic (exogenous subclinical hyperthyroidism)
- Autonomously functioning thyroid adenomas and multinodular goiters (endogenous subclinical hyperthyroidism)
- Graves' disease (endogenous subclinical hyperthyroidism)
- Thyroiditis
- Euthyroid patients with Graves' orbitopathy
- Early Graves'
- Graves' disease in remission
- High hCG

Box 13.11: Cardiac effects of subclinical hyperthyroidism.

- Resting tachycardia
- Coronary heart disease
- Heart failure
- Atrial fibrillation
- Left ventricular hypertrophy
- Increase LV mass index
- Increase cardiac workload
- Diastolic dysfunction (impaired relaxation)
- Increased systolic function at rest
- Impaired systolic response to exercise

Subclinical Hyperthyroidism (Box 13.10)

Q. Write a short note on subclinical hyperthyroidism.

- Defined as **normal** serum free T_4 and T_3 in the presence of **subnormal** TSH (<0.5 mU/L).
- Prevalence between 0.7 and 12.4%
- Natural course: 40–60% normalize. About 0.5-8% progresses to overt hyperthyroidism.
- **Effects of subclinical hyperthyroidism**
- **Cardiac effects** of subclinical hyperthyroidism **(Box 13.11)**.
- **Noncardiac effects**:
  - Osteoporosis
  - Decreased bone mineral density
  - Increased risk of fractures
  - Muscle weakness
  - Dementia, etc.

Thyroiditis

Q. Write a short note on causes of thyroiditis.

- It is a heterogeneous group of **inflammatory disorders involving the thyroid gland.**
- Etiologies range from autoimmune to infectious origins.
- The clinical course may be **acute, subacute, or chronic.**

Causes of Thyroiditis

See **Table 13.15.**

TABLE 13.15: Causes of thyroiditis.

Type	*Causes*
Acute	➢ **Bacterial infections**: *Staphylococcus, Streptococcus, Enterobacter* ➢ **Fungal infections**: *Aspergillus, Candida, Histoplasma* ➢ **Radiation:** After ^{131}I treatment ➢ **Drugs:** Amiodarone (may also be subacute or chronic)
Subacute	➢ Viral or granulomatous (de Quervain's) thyroiditis ➢ Silent thyroiditis (includes postpartum thyroiditis) ➢ Mycobacterial infection ➢ **Drug induced:** Interferon, amiodarone
Chronic	➢ **Autoimmune:** Hashimoto's thyroiditis and Riedel's thyroiditis ➢ **Parasitic thyroiditis:** Echinococcosis, strongyloidiasis, cysticercosis ➢ **Traumatic:** Palpation thyroiditis

Subacute Thyroiditis (De Quervain's Thyroiditis)

Q. Write a short note on subacute thyroiditis (de Quervain's thyroiditis/granulomatous thyroiditis).

- A spontaneously remitting, painful, subacute inflammatory disease of the thyroid characterized by transient inflammation of the thyroid gland.
- Most prevalent in the temperate zone.
- Strongly associated with HLA-B35
- **Gender and age:** Affect women more often than men (3 to 5:1). It is most common in young adults and middle age.

Clinical Features

- **Prodromal viral symptoms:** These are often preceded by a viral infection (e.g., Coxsackie, mumps, adenovirus, measles) of upper respiratory tract. Prodromal symptoms include fever, malaise and pain in the neck with tachycardia, and local thyroid tenderness.
- **Anterior neck pain** in the region of thyroid is the **presenting symptom** is majority of cases and occurs abruptly and may be sometimes unilateral.

  - It **may radiate to the ear, mandible, or occiput**.
  - Pain may shift to the contralateral lobe (**creeping thyroiditis**).
  - Pain may be **aggravated** by **moving the head, swallowing, or coughing**.
- **Functional impairment: Initially** there is **hyperthyroidism followed by euthyroidism** and **later** followed by a period of **hypothyroidism.** Finally, **full recovery occurs in 4–6 months**. In about 5% of cases hypothyroidism may persist.
- **Signs: Enlarged diffusely or asymmetrically** and **tender thyroid gland**.

Laboratory Findings

- **Mildly elevated** serum free T_4 and T_3 and **low** serum TSH
- **Erythrocyte sedimentation rate (ESR):** Elevated (>50 mm/h may exceed 100 mm/h)
- **CRP** may be **elevated**
- **High** serum thyroglobulin
- **Mild** anemia
- **Leukocyte counts:** Normal or slightly elevated
- **Serum IL-6 and Tg concentrations:** Increased during the thyrotoxic phase.
- **Thyroid radionuclide uptake** is reduced or absent.
- **Thyroid antibodies** are **transiently detectable** at low titers in a minority of patients.

Treatment

- **Mild cases:** Salicylates (**aspirin** 2,600 mg daily) or NSAIDS (**naproxen** 500–1000 mg daily in 2 divided doses or **ibuprofen** 1,200–3,200 mg daily in 3–4 divided doses) relieve pain and tenderness.
- **Severe cases:** Corticosteroids (**prednisone** 40 mg/day) have a more dramatic and rapid effect.
- Symptoms of thyrotoxicosis should be managed with β-adrenergic blocking agents (**propranolol** 40–120 mg, **propranolol LA** 80 mg daily or 25–50 mg **atenolol** daily).
- If TSH >10 mU/L or associated with symptoms, 50–100 mg of **levothyroxine** for 6–8 weeks.

Hashimoto's Thyroiditis

Q. Write short essay/note on Hashimoto's (autoimmune) thyroiditis.

- Organ-specific **autoimmune disorder** of thyroid characterized gradual thyroid failure with or without goiter formation by lymphoid infiltration of thyroid leading to apoptosis, fibrosis and atrophy with high titers of circulating:
  - **Antithyroid peroxidase (TPO) antibody (TPOAb)** in 95% patients.
  - **Antithyroglobulin (Tg) antibody** in 60–80% patients.
- **Most common cause** of primary hypothyroidism in iodine sufficient areas of the world.
- The two major forms of Hashimoto's thyroiditis are **goitrous autoimmune thyroiditis** and **atrophic autoimmune thyroiditis** (often called **primary myxedema**). Common pathologic feature being lymphocytic infiltration and follicular destruction.
- **Age and gender:** Most often diagnosed between 50 and 60 years of age, more frequent in women than in men with a sex ratio of approximately 7:1.
- **Association with other autoimmune diseases:** Often associated with ulcerative colitis or type 1 diabetes mellitus, pernicious anemia and Addison's disease.

Pathology

- **Lymphocytic infiltration** (lymphoid follicles with germinal center)
- Fibrosis
- Follicular cell hyperplasia
- Presence of **oxyphil cells** (Ashkenazy cells/Hürthle cells).

Clinical Features

- **Most** patients are **asymptomatic.**
- Some may have a feeling of tightness or fullness in the neck.
- Neck pain and tenderness are rare.
- **Hypothyroidism, the most common cause** of **goitrous hypothyroidism**. About 25% present with hypothyroidism and remaining are at a higher risk of developing in future years.
- **Hashitoxicosis** is seen in the acute phase.
- Chronic autoimmune thyroiditis is a **component of type 2 autoimmune polyglandular syndrome**
- **Physical examination:** Diffuse enlargement of thyroid with firm or rubbery consistency.

Investigations

Q. Investigations and treatment of Hashimoto's thyroiditis.

- **Thyroid function tests:** Show features of **hypothyroidism**
- **Antithyroid peroxidase (TPO) antibody (TPOAb)** in 95% patients
- **Antithyroglobulin (Tg) antibody** in 60–80% patients
- **Antinuclear factor (ANF)** may be found in patients below the age of 20 years
- **Ultrasound of thyroid:** Reduced echogenicity
- **Fine-needle aspiration cytology (FNAC) of thyroid.**

Treatment

Levothyroxine (150–200 μg/day) is indicated for the treatment of hypothyroidism and it may produce shrinkage of goiter. The dose of thyroxine should be sufficient enough to suppress serum TSH to low but detectable levels.

Complication

An increased risk for **thyroid lymphoma** (rare).

Riedel's Thyroiditis (Sclerosing Thyroiditis/Ligneous Thyroiditis/Invasive Fibrous Thyroiditis)

- Rare, chronic inflammatory disorder of unknown etiology.
- Characterized by **dense fibrosis** of the **thyroid gland and adjacent perithyroidal tissues** (parathyroid glands, the recurrent laryngeal nerve and trachea), and extracervical areas (fibrous mediastinitis, retroperitoneal fibrosis, retro-orbital fibrosis, sclerosing cholangitis, and pancreatitis).
- **Women** are four times more likely than men to be affected, and it most commonly occurs between the ages of **30 and 50 years**.

Clinical Features

- Usually present with a long history of a **painless, progressively increasing anterior neck mass**.
- Most patients are euthyroid.
- **Pressure symptoms:**
  - Dysphagia
  - Cough
  - Hoarseness
  - Stridor
  - Attacks of suffocation may be present.
  - Local obstructive pneumonia
  - Superior vena cava syndrome
- **Physical examination:** A **stony-hard or woody thyroid** mass which varies in size from small to very large. It may involve one or both lobes and is **fixed to surrounding structures.**

Investigations

- **Thyroid function test:** 25–67% have subclinical or overt hypothyroidism.
- **Thyroid antibodies:** May be found in about 45% of patients.
- **Serum calcium:** May be low due to parathyroid invasion.
- **Imaging:**
  - **USG** shows heterogeneous **hypoechoic lesions** that may infiltrate the perithyroid muscles
  - **Doppler** shows absence of vascular flow in the Riedel's regions.
  - **CT/MRI** shows extent of fibrosis.
  - Riedel's thyroiditis is hypermetabolic on **FDG-PET**.
- The differential diagnosis based on **FNAC** includes **subacute thyroiditis, a fibrosing variant of Hashimoto's thyroiditis, radiation-induced thyroiditis, and malignancy, specifically a paucicellular variant of anaplastic cancer.**
- **Definitive diagnosis** can be established pathologically only by **open biopsy**, since FNAC may be difficult to interpret due to insufficient thyroid epithelial cells but may reveal mononuclear cells and fibrous tissue.

Treatment

- If untreated, this condition may stabilize or regress.
- **Glucocorticoids** has reduced enlargement and induced softening of mass in a few patients; however, therapy is long-term and it recurs when steroids are tapered.
- **Tamoxifen** 10–20 mg twice daily
- **Rituximab** intravenous 375 mg/m^2 monthly for 3 months
- **Mycophenolate mofetil** 1 g twice daily
- **Surgery:** Indicated to relieve tracheal and esophageal compression or to rule out malignancy. Surgery should be limited to relieve the obstruction and extensive resection is not indicated to avoid injury to adjacent adhering structures.
- **Radiation:** Low dose in cases refractory to other treatment.

Goiter

Goiter is the enlargement of thyroid gland.

Classification (Table 13.16)

TABLE 13.16: Classification of goiter.

Diffuse	*Nodular*
➢ **Simple (nontoxic):** Physiological (puberty, pregnancy), iodine deficiency (endemic goiter) ➢ **Toxic goiter:** Graves' disease ➢ **Autoimmune/inflammatory:** Hashimoto's thyroiditis, de Quervain's thyroiditis, Riedel's thyroiditis ➢ Dyshormonogenesis, goitrogens (e.g., sulfonylureas)	➢ Multinodular goiter, toxic multinodular goiter (Plummer's disease) ➢ Solitary nodular fibrotic (Riedel's thyroiditis) ➢ Cysts ➢ **Tumors:** – Benign: Adenomas – Malignant: Carcinoma and lymphomas ➢ **Miscellaneous:** Sarcoidosis and tuberculosis

Simple (Nontoxic) Goiter

- Diffuse nontoxic (simple) goiter is characterized by the **diffuse enlargement of the thyroid gland without any nodularity**.
- This includes: **Simple hyperplastic goiter** (**colloid goiter**)
- **Causes:**
  - Physiological in pregnancy, puberty
  - Iodine deficiency.
- **Appearance:** Large, smooth firm, and nontender goiter
- **Effect:** Euthyroid and pressure effect.

Risk Factors for Malignancy in Goiter

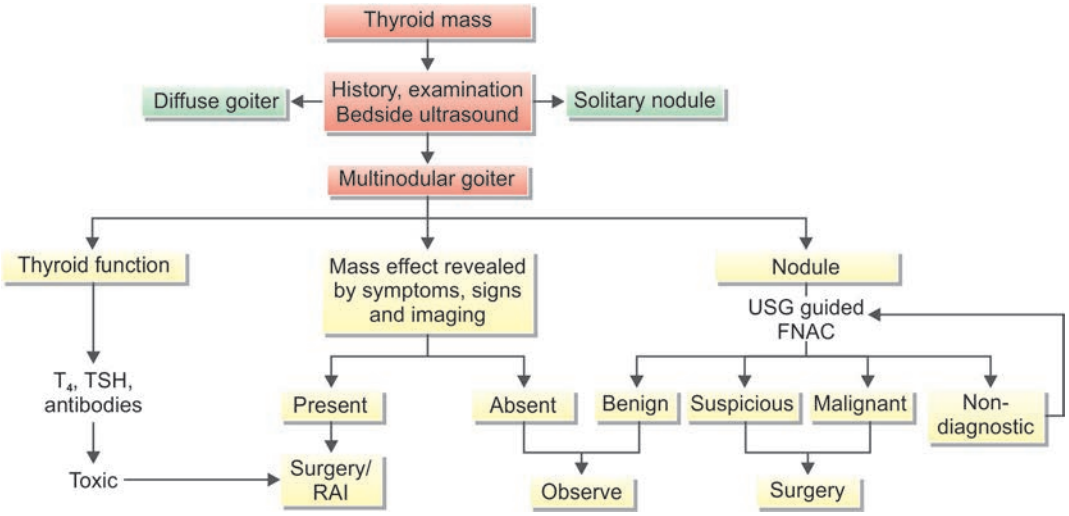
- Solitary thyroid nodules in patients >60 or <30 years of age
- Irradiation of the neck or face during infancy or teenage years
- Past history of surgery
- Presence of cervical lymphadenopathy
- Symptoms of pain or pressure (especially a change in voice)
- Male sex
- Large nodules (>3 or 4 cm)
- Growth of nodule

Diffuse Nontoxic (Simple) Goiter

Q. Write short essay/note on clinical features, investigations and treatment of goiter/multinodular goiter.

Diffuse nontoxic (simple) goiter is characterized by the diffuse enlargement of the thyroid gland without any nodularity (**Flowchart 13.5**).

FLOWCHART 13.5: Algorithm for approach to goiter and its treatment modality.



Thyroid mass
History, examination
Bedside ultrasound
Diffuse goiter
Solitary nodule
Multinodular goiter
Thyroid function
Mass effect revealed by symptoms, signs and imaging
Nodule

T_4, TSH, antibodies
Present
Absent
Benign
Suspicious
Malignant
Non-diagnostic
Toxic
Surgery/ RAI
Observe
Surgery

(FNAC: Fine-needle aspiration cytology; RAI: Radioactive iodine therapy; TSH: Thyroid-stimulating hormone)

Etiology

Types: Endemic and sporadic.

- **Endemic goiter:** This term is used when goiters are present in >10% of the population in a given region. The causes are:
  - **Deficiency of iodine:** This may be due to low iodine in the soil, water and food.
  - **Consequences of iodine deficiency:** Decreased synthesis of thyroid hormone and causes compensatory increase in TSH. This leads to **follicular cell hypertrophy** and **hyperplasia** and goitrous enlargement.
  - **Goitrogens:** These are substances ingestion of which **interferes with thyroid hormone synthesis**. Goitrogenic substances include vegetables which belong to Brassicaceae (Cruciferae) family such as cabbage, cauliflower, Brussels sprouts, and turnips and cassava root which contain a thiocyanate that inhibits iodide transport within the thyroid. Consumption of this may worsen the concurrent iodine deficiency.
- **Sporadic goiter**
  - Less frequent than endemic goiter
  - **Age:** Puberty or in young adult life
  - **Sex:** Female preponderance.
  - **Causes:** In most cases of sporadic goiter the cause is not known.

Clinical Features

- **Endemic goiter:**
  - Diffuse enlargement of the thyroid with euthyroid state in the initial stage. This is called as simple goiter.
  - But later they may develop hypothyroidism.
  - In children and adults, endemic goiter may be present with features of hypothyroidism and mental retardation.
- **Cretinism:**
  - Iodine deficiency may produce severe hormone-induced physiological damage to fetus and newborn and cause cretinism.
  - Stunting
  - Deaf-mutism
  - Malformed limbs
  - Spastic motor disorders
  - Goiter
  - Mental impairment.

Investigations (Refer Flowchart 13.5)

- Serum inorganic iodide: Reduced
- Urinary iodide excretion: Low < 50 µg/day.
- Serum T_4: Normal
- Serum T_3: May be normal or raised due to increased conversion of T_4 to T_3
- TSH: May be normal or mildly raised.

Treatment

- Early stages: Supplementation with iodine.
- Later may need suppressive therapy with T_4.

PARATHYROID DISORDERS

Calcium Homeostasis (Fig. 13.10 and Table 13.17)

Q. PE13.11 Discuss the RDA, dietary sources of Calcium and their role in health and disease.

Distribution of Calcium

- Calcium weight is 400 mg/kg in infants and 950 mg/kg in adults. The RDA for adults is between 1,000–1,200 mg daily, depending on age.
- **Blood Ca^{++} level:** 8.5–10.2 mg/dL. Usually 10 mg/100 mL (so 500 mg total in plasma = 0.5 g).
- About 99% of total body calcium in the **bone.**
- Remaining 1% in **intracellular fluid (ICF), extracellular fluid (ECF), and cell membranes**.
- It can be divided in three components:
  i. 45% ionized
  ii. 40% bound to albumin
  iii. 15% complex with anions (citrate and phosphate).

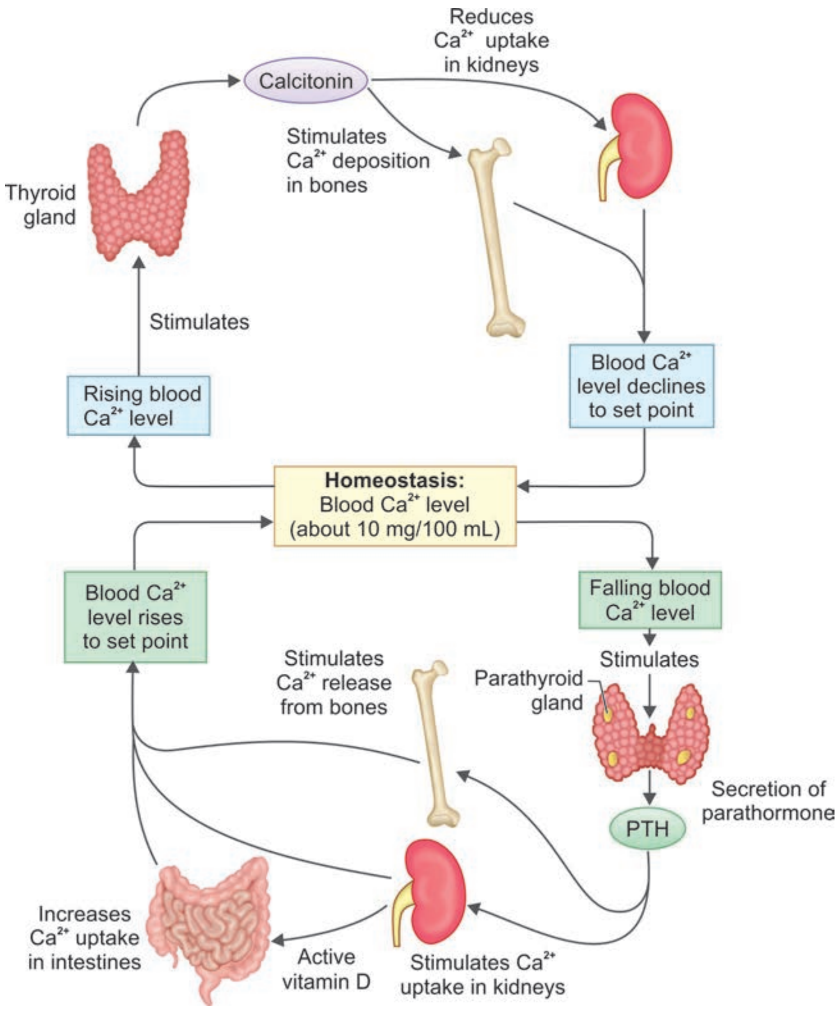
Importance of Ionized Calcium

Ionized calcium (Ca^{++}) is physiologically important because:

- One of the major intracellular messengers
- Precise levels are necessary for muscle contraction (cardiac and skeletal)
- Responsible for exocytosis of secretory granules in neuronal synapses.
- Serves as second messenger in many cells.
- Necessary for blood clotting.

Regulation of Calcium Levels

- It occurs in three different organs namely:
  - i. **Small intestine:** Dietary Ca^{++} is absorbed in an active transcellular pathway in the duodenum and proximal jejunum. Paracellular calcium transport occurs throughout the length of the intestine.
  - ii. **Kidney:** Ionized Ca^{++} is filtered through the nephron, and can be excreted in the urine.
  - iii. **Bone:** Major storage site for Ca^{++}.
- **Calcium cycling in bone tissue:** Two processes that go on continuously and include bone formation and bone resorption.
  - Calcium phosphate crystals are called **"hydroxyapatite"**. The surfaces of crystals can exchange Ca^{++} and phosphate ions with extracellular fluid.
  - **Osteoblasts:** Synthesize a collagen matrix that holds calcium phosphate in crystallized form. Once surrounded by bone, osteoblast becomes osteocyte.
  - **Osteoclasts:** They break down bone (removes Ca^{++} from bone). Change local pH, causing Ca^{++} and phosphate to dissolve from crystals into extracellular fluids.



Reduces Ca^{2+} uptake in kidneys
Calcitonin
Stimulates Ca^{2+} deposition in bones
Thyroid gland
Stimulates
Rising blood Ca^{2+} level
Blood Ca^{2+} level declines to set point
Homeostasis: Blood Ca^{2+} level (about 10 mg/100 mL)
Blood Ca^{2+} level rises to set point
Falling blood Ca^{2+} level
Stimulates
Stimulates Ca^{2+} release from bones
Parathyroid gland
Secretion of parathormone
PTH
Increases Ca^{2+} uptake in intestines
Active vitamin D
Stimulates Ca^{2+} uptake in kidneys

FIG. 13.10: Calcium metabolism.

TABLE 13.17: Hormonal regulators of calcium homeostasis.

Calcitonin (CT)	*Parathormone (PTH)*	*Vitamin D (1, 25 vitamin D_3)*
➢ Secreted from the parafollicular/C-cells in the thyroid gland. ➢ Actions: – Lowers Ca^{++} in blood. – Promotes deposition of Ca^{++} into bone. – It inhibits bone resorption by osteoclasts. ➢ **Control of secretion:** Increased plasma Ca^{++} stimulates C-cells to synthesize and release calcitonin.	➢ Secreted from cells of the parathyroid glands (chief cells). ➢ **Actions:** – Increases Ca^{++} in the blood – Increases Ca^{++} resorption from the bone – Stimulates the osteoclasts – Increases the number of osteoclasts – Increases Ca^{++} resorption from the pre-urine filtrate in the nephron.	➢ **Actions:** Vitamin D increases: – Calcium absorption from intestine. – PO_4 absorption from intestine. – Renal reabsorption of Ca and PO_4. – Bone resorption from old bone and mineralize new bone (net resorption). ➢ **Overall effect:** Increases serum Ca and PO_4.

Hyperparathyroidism

Q. IM22.2 **Describe the etiology, clinical manifestations, diagnosis and clinical approach to primary hyperparathyroidism.**

Q. Write a short essay on clinical features, investigations, and management of primary hyperparathyroidism.

Q. Write a short essay on classification of hyperparathyroidism.

Classification and Causes of Hyperparathyroidism (Table 13.18)

TABLE 13.18: Classification and causes.

Type	*Calcium*	*PTH*	*Causes*
Primary Autonomous secretion of PTH by parathyroid	Raised	Raised	Single adenoma (90%), multiple adenomata, nodular hyperplasia and carcinoma of parathyroid
Secondary Parathyroid hyperplasia with increased PTH secretion in an attempt to compensate for prolonged hypocalcemia	Low	Raised	Chronic renal failure, malabsorption, osteomalacia, and rickets
Tertiary Adenoma formation and autonomous PTH secretion. Occurring in cases of secondary hyperparathyroidism	Raised	Raised	Chronic secondary hyperparathyroidism Postrenal transplantation

Clinical Features of Hyperparathyroidism

- The most common clinical presentation of primary hyperparathyroidism (>70%) is asymptomatic hypercalcemia detected by routine biochemical screening
- **Classical symptoms of primary hyperparathyroidism** are described by the adage "*moans, bones, stones, abdominal groans*". However, nowadays only few patients present in this way:
  - **Moans:** Psychiatric manifestations—lethargy, fatigue, depression, memory loss, psychoses, neuroses, paranoia, confusion, stupor, and coma
  - **Bones:** Arthritis, osteomalacia, and osteitis
  - **Stones:** Renal stones, uremia, polydipsia, and polyuria
  - **Abdominal groans:** Constipation, nausea, vomiting, peptic ulcers, indigestion, and pancreatitis
- **Nonspecific symptoms**: About 50% of patients are asymptomatic while others have nonspecific symptoms. These include: anorexia, nausea, vomiting, constipation, weakness, fatigue, lassitude, tiredness, generalized aches, weight loss, pain, drowsiness, poor concentration, memory loss, and depression.
- **Manifestations of hyperparathyroidism:** Involve primarily the **kidneys** and the **skeletal system**.
  - **Renal manifestations:** Due either to deposition of calcium in the renal parenchyma or to recurrent nephrolithiasis.
    - **Recurrent renal calculi** (usually composed of either calcium oxalate or calcium phosphate)
    - **Nephrocalcinosis:** Deposition of calcium salts in the renal parenchyma.
    - Polyuria and polydipsia
    - Loss of renal function with uremia, hypokalemia, hyperuricemia, hyperchloremic acidosis, and dilute urine.
  - **Skeletal manifestations**
    - Bone pain, osteopenia, osteoporosis, fractures, and deformity due to osteitis fibrosa cystica (10–25% of patients)
    - Localized bone swelling/brown tumor (e.g., mandible).
  - **Other manifestations**
    - Hypertension is a common feature.
    - Calcification of cornea (observed by slit-lamp examination), arterial walls, and soft tissues of hand.
    - Peptic ulcers
    - Myopathy
  - A family history of hypercalcemia or primary hyperparathyroidism secondary to a parathyroid adenoma raises the possibility of multiple endocrine neoplasia (MEN) syndrome. Features of multiple endocrine neoplasia syndromes are presented in **Box 13.12**.

Box 13.12: Features of multiple endocrine neoplasia (MEN) syndromes.

MEN 1 (Wermer's syndrome)

- Parathyroid hyperplasia (very common)
- Pancreatic tumors (benign or malignant)
  - Gastrinoma
  - Insulinoma
  - Glucagonoma
  - VIPoma
- Pituitary tumor
  - Growth hormone-secreting
  - Prolactin-secreting
  - Adrenocorticotropic hormone (ACTH)-secreting
- Other tumors: Lipomas, carcinoids, adrenal, and thyroid adenomas

MEN 2A (Sipple syndrome)

- Medullary carcinoma of the thyroid
- Pheochromocytoma (benign or malignant)
- Parathyroid hyperplasia

MEN 2B

- Medullary carcinoma of the thyroid
- Pheochromocytoma
- Mucosal neuromas and ganglioneuromas
- Marfanoid habitus
- Hyperparathyroidism (very rare)

Investigations

- **Biochemical investigations:** Estimation of several fasting serum calcium and phosphate samples should be done.
- **Hallmark of primary hyperparathyroidism:**
  - **Hypercalcemia** and **hypophosphatemia** with **detectable or elevated intact PTH levels** during hypercalcemia. When this combination is present in an asymptomatic patient then further investigation is usually unnecessary. Established hypercalcemia in more than one serum measurement accompanied by elevated immunoreactive PTH (iPTH) is characteristic.
  - Serum concentrations of 1,25-dihydroxy vitamin D may therefore be at upper limits of normal or elevated.
  - **Correction of serum calcium concentrations:** It should be corrected to the prevailing serum albumin concentration. Calcium level is corrected for low albumin levels by adding 0.8 mg/dL to the total serum calcium level for every 1.0 g/dL by which the serum albumin concentration is lower than 4 g/dL.
  - May be associated with **mild hyperchloremic acidosis**.
  - **Calcium/creatinine (Ca/Cr) clearance ratio (Fig. 13.11):** [24-hour urine Ca x serum Cr] ÷ [serum Ca × 24-hour urine Cr]
- **Urine investigations**
  - **Hypercalciuria (24 hours urinary calcium)** (>200–300 mg/24 hours): Observed in ~30% of patients.
  - **Increased markers of bone resorption:** These include urinary pyridinoline, deoxypyridinoline, and N-telopeptide of collagen.
- **ECG findings**
  - Shortened QT interval
  - Rarely cardiac arrhythmias
  - Rarely ST-segment elevation
- **Radiological abnormalities**
  - Most sensitive and specific radiologic finding of **osteitis fibrosa cystica** is **subperiosteal resorption of cortical bone**, best seen in high-resolution films of the phalanges.
  - A similar process in the **skull** leads to a **salt-and-pepper appearance**.
  - Bone cysts or **brown tumors** may be evident as osteolytic lesions.
  - The other important skeletal consequence of hyperparathyroidism is **osteoporosis**. Unlike other osteoporotic disorders, hyperparathyroidism often results in the preferential loss of cortical bone.
  - Dental films may disclose loss of the lamina dura of the teeth, but this is a nonspecific finding also seen in periodontal disease.
  - **Nephrocalcinosis:** Appears as scattered opacities within the renal outline.
  - **Soft tissue calcification:** For example, calcification of arterial wall.
  - **Dual-energy X-ray absorptiometry (DEXA) and CT scan:** Reveal reduced bone density.
- **Investigations for localization of the tumor:** Parathyroid imaging is generally indicated only for patients who have undergone previous parathyroid surgery. Investigations to localize the tumor include:

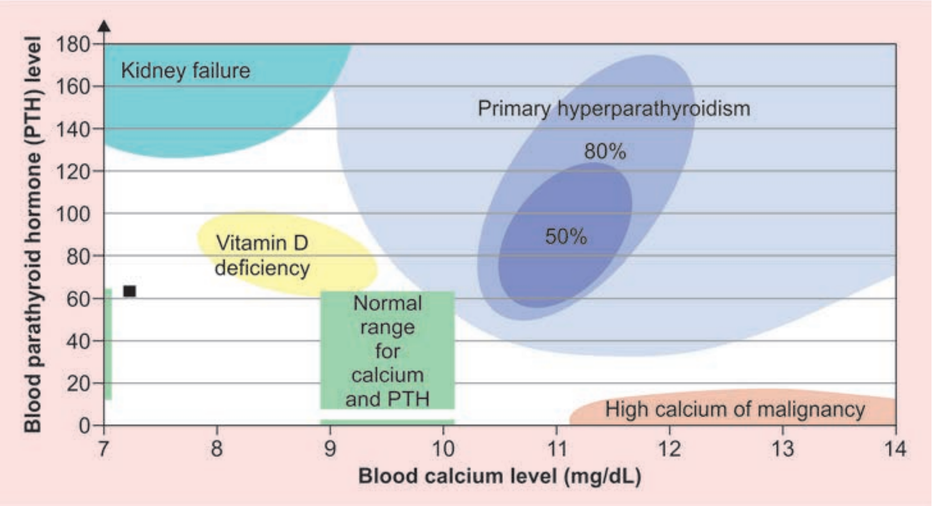


FIG. 13.11: Graphic representation of relationship between calcium and parathormone.

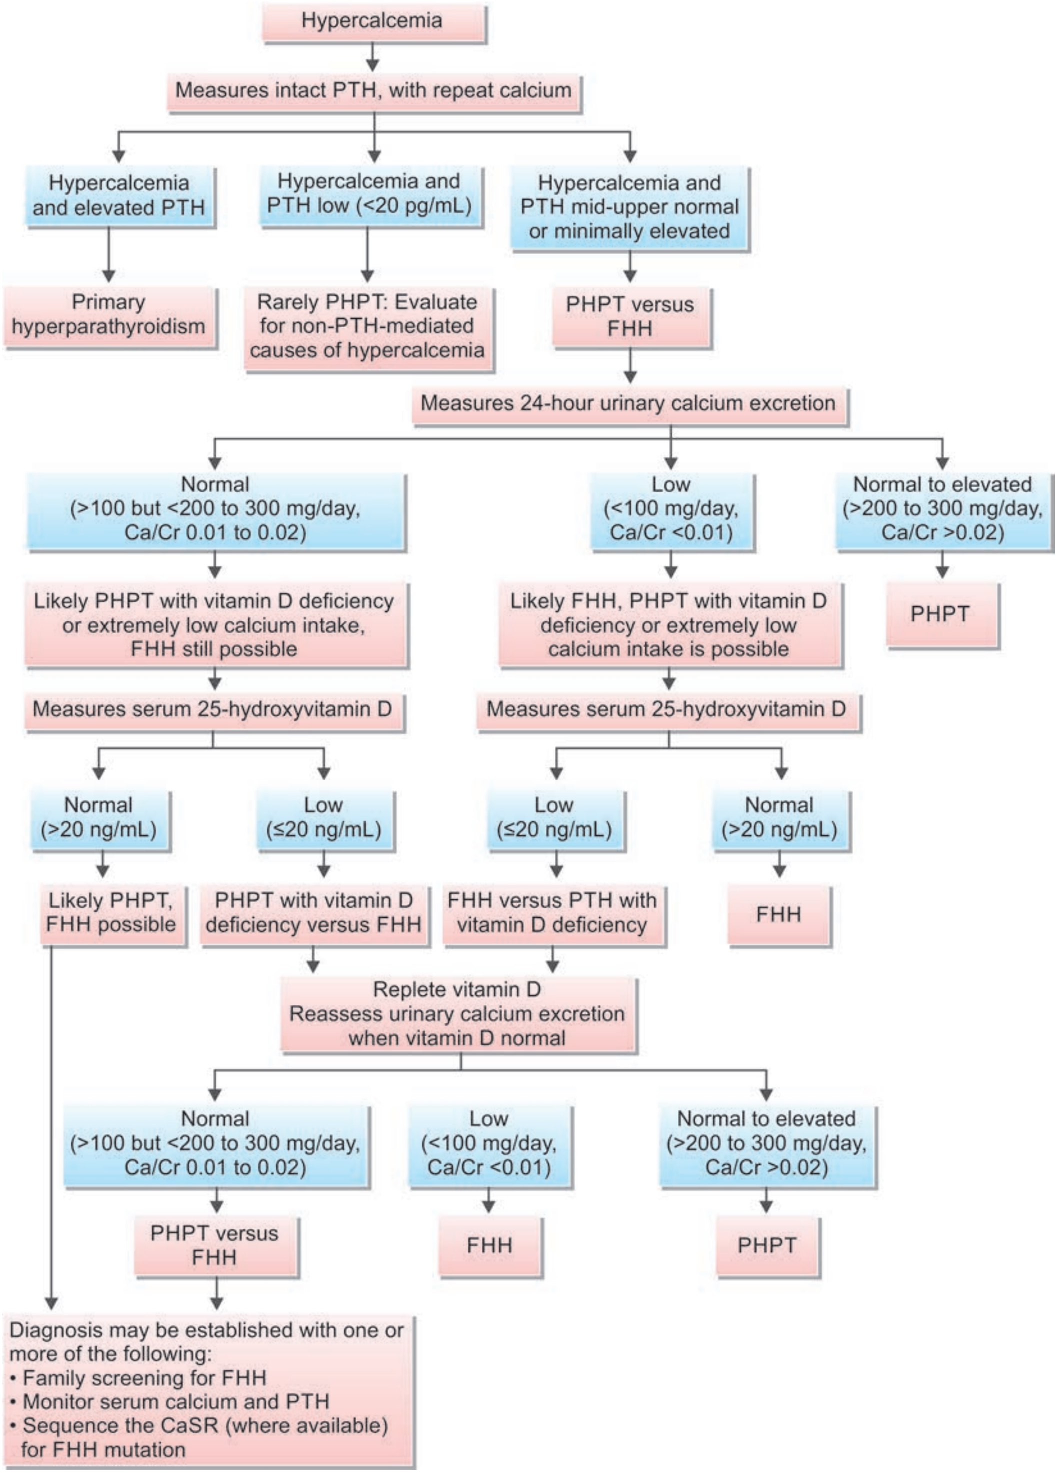
- **High-resolution ultrasonography**, **CT scanning** and **subtraction imaging** and **scintigraphy** with technetium 99m sestamibi.
- **Selective neck vein catheterization** with PTH estimation.

Diagnosis of primary hyperparathyroidism has been shown in **Flowchart 13.6.**

FLOWCHART 13.6: Diagnosis of primary hyperparathyroidism.



Hypercalcemia
Measures intact PTH, with repeat calcium
Hypercalcemia and elevated PTH
Hypercalcemia and PTH low (<20 pg/mL)
Hypercalcemia and PTH mid-upper normal or minimally elevated
Primary hyperparathyroidism
Rarely PHPT: Evaluate for non-PTH-mediated causes of hypercalcemia
PHPT versus FHH
Measures 24-hour urinary calcium excretion
Normal (>100 but <200 to 300 mg/day, Ca/Cr 0.01 to 0.02)
Low (<100 mg/day, Ca/Cr <0.01)
Normal to elevated (>200 to 300 mg/day, Ca/Cr >0.02)
Likely PHPT with vitamin D deficiency or extremely low calcium intake, FHH still possible
Likely FHH, PHPT with vitamin D deficiency or extremely low calcium intake is possible
PHPT
Measures serum 25-hydroxyvitamin D
Measures serum 25-hydroxyvitamin D
Normal (>20 ng/mL)
Low (≤20 ng/mL)
Low (≤20 ng/mL)
Normal (>20 ng/mL)
Likely PHPT, FHH possible
PHPT with vitamin D deficiency versus FHH
FHH versus PTH with vitamin D deficiency
FHH
Replete vitamin D Reassess urinary calcium excretion when vitamin D normal
Normal (>100 but <200 to 300 mg/day, Ca/Cr 0.01 to 0.02)
Low (<100 mg/day, Ca/Cr <0.01)
Normal to elevated (>200 to 300 mg/day, Ca/Cr >0.02)
PHPT versus FHH
FHH
PHPT
Diagnosis may be established with one or more of the following:
• Family screening for FHH
• Monitor serum calcium and PTH
• Sequence the CaSR (where available) for FHH mutation

(FHH: Familial hypocalciuric hypercalcemia; PTH: Parathyroid hormone; PHPT: Primary hyperparathyroidism)

Treatment

- **Primary hyperparathyroidism**
  - Patients with **symptomatic** primary hyperparathyroidism should undergo **parathyroid surgery** which is the only definitive therapy. In primary hyperparathyroidism, an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m^2 is an indication for parathyroidectomy.
  - Guidelines for surgery in asymptomatic primary hyperparathyroidism: Any **ONE** of the following criteria:
    - Serum calcium: >1 mg/dL above the upper limit of normal.
    - BMD by DXA: T-score <–2.5 at lumbar spine, total hip, femoral neck, or distal one-third radius.
    - Vertebral fracture by radiograph, CT, MRI, or VFA.
    - Creatinine clearance <60 mL/min
    - 24-hour urine for calcium >400 mg/day and increased stone risk by biochemical stone risk analysis.
    - Presence of nephrolithiasis or nephron-calcinosis by radiograph, ultrasound, or CT.
    - Age <50 years
  - For patients who are **unable to have surgery** and whose primary indication for surgery is symptomatic and/or severe hypercalcemia, **cinacalcet** is preferred over bisphosphonates.
  - **Cinacalcet:** In primary hyperparathyroidism, initially: Oral, 30 mg twice daily; increase dose incrementally every 2–4 weeks (to 60 mg twice daily, 90 mg twice daily, and 90 mg 3 or 4 times daily) as necessary to normalize serum calcium levels.
- **Secondary hyperparathyroidism**
  - Treatment of chronic kidney disease (CKD)
  - According to Kidney Disease Outcomes Quality Initiative (KDOQI) guidelines, in all dialysis patients, serum phosphate should be maintained between 3.5–5.5 mg/dL, serum calcium should be maintained <9.5 mg/dL and PTH values should be maintained less than two to nine times the upper limit for the PTH assay.
  - Treatment options for increased PTH include **calcimimetics, calcitriol, or synthetic vitamin D analogs**.
  - **Cinacalcet**: In secondary hyperparathyroidism, initially orally: 30 mg once daily; increase dose incrementally every 2 to 4 weeks as necessary to maintain intact parathyroid hormone (iPTH) level between 150 and 300 pg/mL. May be used alone or in combination with vitamin D and/or phosphate binders.
- **Tertiary hyperparathyroidism: Parathyroidectomy**

Refractory Hyperparathyroidism

- Defined as **persistent** and **progressive** elevations of serum PTH, that cannot be lowered to levels < 600 pg/mL despite treatment with vitamin D derivatives and cinacalcet and without causing significant hyperphosphatemia or hypercalcemia.
- Patients with severe disease may require parathyroidectomy.

Hypercalcemia

Q. IM22.3 Describe the approach to the management of hypercalcemia.

Q. Write short essay/note on hypercalcemia.

- Normal serum calcium level is **8–10 mg/dL** (2.0–2.5 mmol/L)
- Normal ionized calcium levels are **4–5.6 mg/dL** (1–1.4 mmol/L).
- **Raised calcium level** is known as hypercalcemia.
- Hypercalcemia is considered as **mild** if the total serum calcium level is between 10.5 and 12 mg/dL (2.6–3 mmol/L), **moderate** 12–14 mg/dL and **severe** when the level is above 14 mg/dL.
- Hypercalcemia is one of the **most common biochemical abnormalities**. It is often detected incidentally during routine biochemical investigation in asymptomatic patients. However, it can present with chronic symptoms and occasionally as an acute emergency.
- In patients with hypoalbuminemia or hyperalbuminemia, the measured calcium concentration should be corrected in view of the albumin abnormality.

Causes of Hypercalcemia (Table 13.19)

Q. Write short essay/note on causes of hypercalcemia.

TABLE 13.19: Causes of hypercalcemia.

Parathyroid hormone related with normal or elevated PTH levels ➢ Primary hyperparathyroidism (the most common) or tertiary hyperparathyroidism ➢ MEN syndromes ➢ Lithium therapy—induced hyperparathyroidism ➢ Familial hypercalciuric hypercalcemia	**Vitamin D related with low PTH levels** ➢ Vitamin D intoxication: Iatrogenic or self-administered excess ➢ Granulomatous diseases (sarcoidosis, tuberculosis, and berylliosis) ➢ Lymphoma ➢ Idiopathic hypercalcemia of infancy
Malignancy related with Low PTH levels (second most common cause) ➢ Multiple myeloma ➢ PTH related protein secretion: Tumors of lung and kidney ➢ Secondary deposits in bone: Breast carcinoma ➢ Production of osteoclastic factors by tumors	**High bone turnover** ➢ Long-term immobilization ➢ Hyperthyroidism ➢ Drugs: For example, thiazide diuretics, etc. ➢ Paget's disease with immobilization
Associated with renal failure ➢ Secondary hyperparathyroidism ➢ Aluminum toxication	**Excessive calcium intake** ➢ Milk-alkali syndrome ➢ Parenteral nutrition

(PTH: parathyroid hormone)

Clinical Features

(Refer clinical features of hyperparathyroidism above).

Q. Write a short essay/note on the management of hypercalcemia.

Management: Treatment of acute hypercalcemia

- **Adequate rehydration and volume expansion** are essential, usually at least 4–6 L of 0.9% saline on day 1, and 3–4 L for several days thereafter.
- Diuretics after correction of volume (not recommended in the present day due to potential complications and the availability of drugs that inhibit bone resorption, which is primarily responsible for the hypercalcemia). For example, **furosemide** 40–160 mg/day or **ethacrynic acid** 50–200 mg/day. Forced diuresis with 4–6 L of intravenous fluid/day and furosemide 2 hourly.
- Sodium, potassium, and magnesium should be supplemented. Saline decreases concomitant reabsorption of sodium and calcium in both the proximal and distal renal tubules, and enhances urinary excretion of calcium.
- **Intravenous bisphosphonate** is the treatment of choice for hypercalcemia of malignancy or of undiagnosed cause. Concurrent administration of **zoledronic acid** 4 mg IV over 15 minutes or **pamidronate** 60–90 mg over 2 hours.
- **Calcitonin** (4 IU/kg IV 6-hourly), tachyphylaxis develops after 24–48 hours.
- **Prednisolone** (20–40 mg daily) is effective in few instances (e.g., in myeloma, lymphoma, sarcoidosis, and vitamin D excess).
- Oral phosphate (sodium cellulose phosphate) 5 g three times daily.
- **Denosumab**: For hypercalcemia refractory to ZA or in patients in whom bisphosphonates are contraindicated due to severe renal impairment. Starting dose 120 mg every 4 weeks.
- **Cinacalcet**: Reduces the serum calcium in patients with severe hypercalcemia due to parathyroid carcinoma and in hemodialysis patients with an elevated calcium-phosphorous product and secondary hyperparathyroidism.
- **Dialysis**: Treatment of last resort, HD with little or no calcium in the dialysis fluid.

Hypoparathyroidism

Q. Write a short note on causes and general management of hypoparathyroidism.

Deficient secretion of PTH which manifests itself biochemically by:

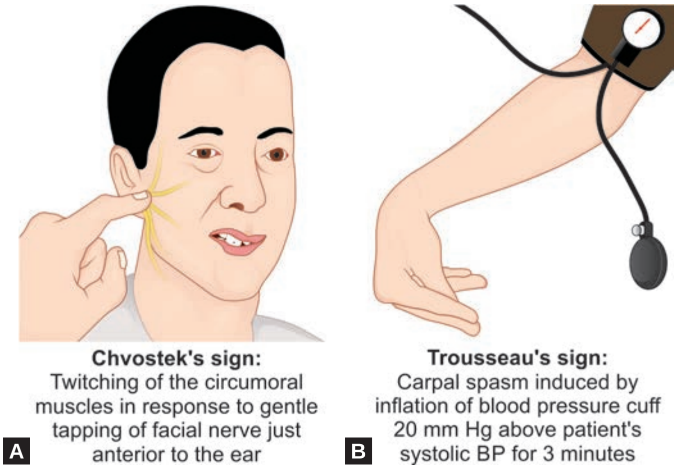
- Hypocalcemia
- Hyperphosphatemia
- Diminished or absent circulating iPTH and
- Clinically the symptoms of neuromuscular hyperactivity.

Causes of Hypoparathyroidism

- **Surgical hypoparathyroidism:** It is the most common. It may be due to the removal of the parathyroid glands or due to interruption of blood supply to the parathyroid glands. Postparathyroidectomy (**hungry bone syndrome**)
- **Idiopathic hypoparathyroidism**
  - Occurs at an **early age** (genetic origin) with autosomal recessive mode of transmission "multiple endocrine deficiency–autoimmune-candidiasis (**MEDAC**) syndrome".
  - "Juvenile familial endocrinopathy"—"Hypoparathyroidism—Addison's disease—mucocutaneous candidiasis (HAM) syndrome"
  - Circulating antibodies for the parathyroid glands and the adrenals are frequently present.
  - Other associated disease: Pernicious anemia, ovarian failure, autoimmune thyroiditis, and diabetes mellitus.
- **Infantile hypoparathyroidism**
- **Infiltrative diseases**: Granulomatous, iron overload, and metastases
- **Radiation-induced destruction**
- **Human immunodeficiency virus (HIV)**
- **Pseudohypoparathyroidism** (resistance to PTH)
- **Functional hypoparathyroidism:** In patients who has chronic hypomagnesemia of various causes. Magnesium is necessary for the PTH release from the glands and also for the peripheral action of the PTH.
- **DiGeorge syndrome** is a familial condition where the hypoparathyroidism is associated with intellectual impairment, cataracts and calcified basal ganglia, and occasionally with specific autoimmune disease.
- **Malabsorption syndrome:** Presumably secondary to decreased calcium level and may lead to steatorrhea with longstanding untreated disease.

Clinical Features

- **Acute**:
  - Neuromuscular irritability (**tetany**)
  - Paresthesia (perioral and extremities)
  - Muscle twitching
  - Carpopedal spasm
  - Chvostek's sign **(Fig. 13.12A)**
  - Trousseau's sign **(Fig. 13.12B)**
  - Seizures
  - Laryngospasm
  - Bronchospasm
  - Prolonged QT interval
  - Hypotension, heart failure, and arrhythmia
  - Papilledema
- **Chronic:**
  - Ectopic calcification (basal ganglia)
  - Extrapyramidal signs
  - Parkinsonism
  - Dementia
  - Subcapsular cataracts
  - Abnormal dentition
  - Dry skin



Chvostek's sign: Twitching of the circumoral muscles in response to gentle tapping of facial nerve just anterior to the ear

Trousseau's sign: Carpal spasm induced by inflation of blood pressure cuff 20 mm Hg above patient's systolic BP for 3 minutes

FIGS. 13.12A AND B: Chvostek's sign and Trousseau's sign.

Treatment

- To effectively treat hypocalcemia in patients with magnesium deficiency, hypomagnesemia should be corrected first.
- **Acute cases**:
  - **Symptomatic: IV calcium** (initially, 10 mL ampule of 10% **calcium gluconate** in 50 mL of 5% dextrose infused over 10–20 minutes, followed by an intravenous infusion of calcium gluconate) with oral **calcitriol** (0.5 µg two times daily).
  - **Asymptomatic:** IV calcium if serum corrected calcium is ≤7.5 mg/dL. Oral calcium (1–4 g of **calcium carbonate** daily in divided doses) should be initiated as soon as the patient is able to take supplements orally.
- **Chronic cases:**
  - **Calcium: Calcium carbonate** or **calcium citrate** 1,000–2,000 mg daily in divided doses.
  - **Vitamin D:**
    - **Calcitriol** (drug of choice)**:** Initial: 0.25–0.5 µg daily and maintenance: 0.5–2 µg daily
    - **Alfacacidol:** Initial 0.25 µg daily and maintenance 0.5–1 µg daily
    - **Dihydrotachysterol:** 0.2–1.2 mg daily.
  - **Hydrochlorothiazide:** If needed for hypercalciuria, 12.5–50 mg daily
  - Second-line therapy by subcutaneous **recombinant human PTH**.

Tetany

It is characterized by **neuromuscular irritability** manifested clinically by **sensory, muscular dysfunction** and **autonomic manifestations**.

Causes of Tetany (Fig. 13.13 and Table 13.20)

Q. PE13.12 Describe the causes, clinical features, diagnosis and management of calcium deficiency.

- Tetany is caused due to **hypocalcemia** or **alkalosis** or **hypomagnesemia**.
- Respiratory alkalosis alone (e.g., hyperventilation) can cause tetany, even in the absence of underlying hypocalcemia.
- Tetany is unusual among patients with chronic renal failure and hypocalcemia (occasionally severe) because of the protective effect of concurrent metabolic acidosis.
- Occurs when there is acute fall in **serum ionized calcium to <4.3 mg/dL** and **total calcium concentration to 7–7.5 mg/dL**.

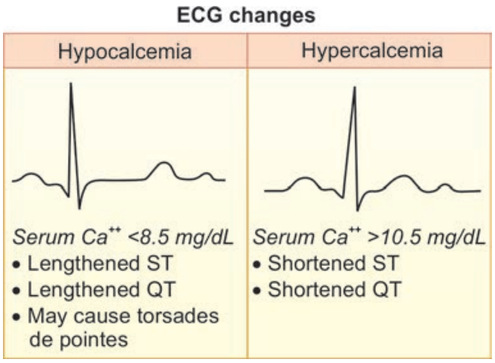


FIG. 13.13: ECG changes in hypo/hypercalcemia.

TABLE 13.20: Causes of tetany.

Due to hypocalcemia	
Increased phosphate levels ➢ Chronic renal failure (common) ➢ Phosphate therapy	**Vitamin D deficiency** ➢ Osteomalacia/rickets ➢ Vitamin D resistance
Hypoparathyroidism ➢ Surgical—after neck exploration (thyroidectomy, parathyroidectomy—common) ➢ Congenital deficiency (DiGeorge syndrome) ➢ Idiopathic hypoparathyroidism (rare) ➢ Severe hypomagnesemia	**Others** ➢ Acute pancreatitis (quite common) ➢ Citrated blood in massive transfusion (not uncommon) ➢ Low plasma albumin, e.g., malnutrition, chronic liver disease ➢ Malabsorption, e.g., celiac disease
Resistance to PTH Pseudohypoparathyroidism	**Drugs** ➢ Calcitonin ➢ Bisphosphonates
Due to alkalosis	
➢ Repeated vomiting of gastric juice ➢ Excessive intake of oral alkali	➢ Hyperventilation, e.g., hysteria ➢ Primary hyperaldosteronism
Due to hypomagnesemia	

Clinical Features

Q. Write a short essay/note on clinical features of tetany.

- Symptoms begin with **perioral and acral paresthesia** leading to hyperventilation—respiratory alkalosis—exacerbation of paresthesia.
- **Motor symptoms:** Stiffness, clumsiness, myalgia, muscle spasms, cramps, carpal spasm, spasm of the respiratory muscles, and laryngismus stridulus.
- **Autonomic manifestations** are diaphoresis, bronchospasm, and biliary colic.

Q. Write a short note on Chvostek's sign and Trousseau's sign (*Refer* Figs. 13.10A and B).

The classic physical findings in patients with neuromuscular irritability due to latent tetany **are:**

- **Chvostek's sign:** It is elicited by tapping the skin over the facial nerve in front of the external auditory meatus. It causes an **ipsilateral contraction of the facial muscles**, but up to 10% of normal population has a positive test.
- **Trousseau's sign:** Inflate BP cuff on arm to 20 mm Hg > systolic BP for 3 minutes and watch for **carpopedal spasm** [flexion at the wrist, flexion at the metatarsophalangeal (MP) joints, extension of the interphalangeal (IP) joints adduction thumbs/fingers]. It may also be induced by voluntary hyperventilation for 1–2 minutes after release of the cuff.

Q. Write a short essay/note on management of tetany.

Treatment

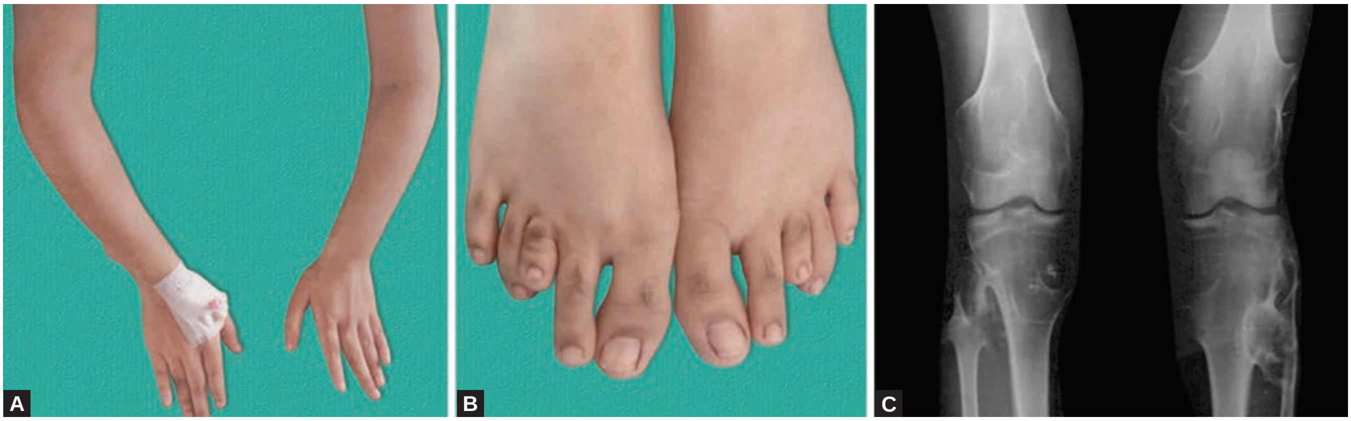
- **Control of tetany**
  - **Calcium gluconate:** Slow intravenous (over 10 minutes) injection of 20 mL of 10% solution of calcium gluconate is rapidly effective in controlling the tetany.
  - **Magnesium:** If tetany is not relieved by above treatment, administration of magnesium may be necessary.
- **Correction of alkalosis**
  - If alkalosis is due to persistent vomiting, treat with **intravenous isotonic saline and potassium**.
  - In alkalosis is due to alkali excess, it should be withdrawn. If needed, ammonium chloride 2 g 4 hourly orally will control tetany.
- **Hysterical hyperventilation:** It may be controlled by **rebreathing expired air from a suitable bag** or inhalation of 5% carbon dioxide in oxygen.

Pseudohypoparathyroidism (PHP)

- PHP is an inherited disorder of **target-organ unresponsiveness to PTH.**
- It mimics hormone-deficient forms of hypoparathyroidism, with **hypocalcemia and hyperphosphatemia**, but the **PTH level is elevated.**

Clinical Features

- **PHP type IB** is a disorder of isolated resistance to PTH, which presents with the biochemical features of hypocalcemia, hyperphosphatemia, and secondary hyperparathyroidism.



FIGS. 13.14A TO C: Albright's hereditary osteodystrophy (AHO): (A) Brachydactyly; (B) Shortened metatarsals; (C) X-ray of knee region.

- **PHP type IA** has, in addition to these biochemical features, a characteristic somatic phenotype known as **Albright's hereditary osteodystrophy (AHO) (Figs. 13.14A to C).** This consists of short stature, round face, short neck, brachydactyly, shortened metatarsals, subcutaneous ossifications, and mental retardation. Due to shortening of the metacarpal bones—most often the fourth and fifth metacarpals—affected digits have a dimple, instead of a knuckle, when a fist is made.
- Certain individuals in families with PHP inherit the somatic phenotype of AHO without any disorder of calcium metabolism; this state is called **pseudopseudohypoparathyroidism or PPHP.**

ADRENAL GLAND DISORDERS

Hormones Secreted by the Adrenal Gland (Table 13.21)

Q. BI6.13 Describe the functions of adrenal gland.

Q. Write a short note on hormones secreted by the adrenal gland.

TABLE 13.21: Various hormones secreted by adrenal gland.

Site	*Category*	*Hormone produced*
Adrenal cortex		
Zona glomerulosa	Mineralocorticoid	Aldosterone
Zona fasciculata	Glucocorticoid	Cortisol
Zona reticularis	Androgens	➢ Dehydroepiandrosterone sulfate ➢ Dehydroepiandrosterone ➢ Androstenedione
Adrenal medulla		
	Catecholamines	Adrenaline Noradrenaline

Cushing's Syndrome

Q. PA32.8 Describe the etiology, pathogenesis, manifestations, laboratory, morphologic features, complications of Cushing's syndrome.

Q. Write a short essay on causes, clinical features, investigations, and management of Cushing's syndrome.

- **Cushing's syndrome** is the term used to describe the **clinical state of increased free circulating glucocorticoid.**
- It occurs most often following the therapeutic administration of synthetic steroids or ACTH.

Q. Write a short essay on Cushing's disease.

- **Cushing's disease** results from **corticosteroid excess** due to **pituitary dependent bilateral adrenal hyperplasia**.
- The pituitary tumors producing Cushing's disease are usually microadenomas (<10 mm in size) which usually do not cause symptoms by local mass effect.
- It usually develops sporadically but may be a component of multiple endocrine neoplasia type 1.
- All the spontaneous forms of the syndrome are rare.

Causes of Cushing's Syndrome (Table 13.22)

Common causes of ectopic ACTH secretion (Box 13.13)

A **Cushingoid appearance** can be caused by excess alcohol consumption (pseudo-Cushing's syndrome)—the pathophysiology is poorly understood.

TABLE 13.22: Causes of Cushing's syndrome.

ACTH-dependent causes	*ACTH-independent causes*
➢ ACTH-secreting pituitary tumor **(Cushing's disease)**—68% ➢ Nonpituitary ACTH-secreting neoplasm (ectopic ACTH syndrome)—12% ➢ CRH-secreting neoplasm (ectopic CRP syndrome)—<1%	➢ Adrenal adenoma—10% ➢ Adrenal carcinoma—8% ➢ Micronodular hyperplasia—<1% ➢ Macronodular hyperplasia—<1% ➢ McCune-Albright syndrome ➢ Iatrogenic (use of corticosteroids)

(ACTH: Adrenocorticotropic hormone)

Box 13.13: Common causes of ectopic ACTH secretion.

Types of tumor	*Percentage*
Small cell carcinoma of the lung	50%
Endocrine tumors of foregut origin	35%
• Thymic carcinoid	
• Pancreatic islet cell tumor	
• Medullary carcinoma thyroid	
• Bronchial carcinoid	
Pheochromocytoma	5%
Ovarian tumors	2%

(ACTH: Adrenocorticotropic hormone)

Box 13.14: Mnemonic for Cushing's syndrome.

C-**C**entral obesity, **C**ollagen fiber weakness, and **C**omedones (acne)
U-**U**rinary free cortisol increased along with glucose
S-**S**triae and **S**uppressed immunity
H-**H**ypercortisolism, **H**ypertension, **H**yperglycemia, and **H**ypercholesterolemia
I-**I**atrogenic due to administration of corticosteroids
N-**N**oniatrogenic and **N**eoplasms
G-**G**lucose intolerance and **G**rowth retardation

Clinical Features (Figs. 13.15 and 13.16A to D, Box 13.14, and Table 13.23)

Q. Write a short essay on major signs of Cushing's syndrome.

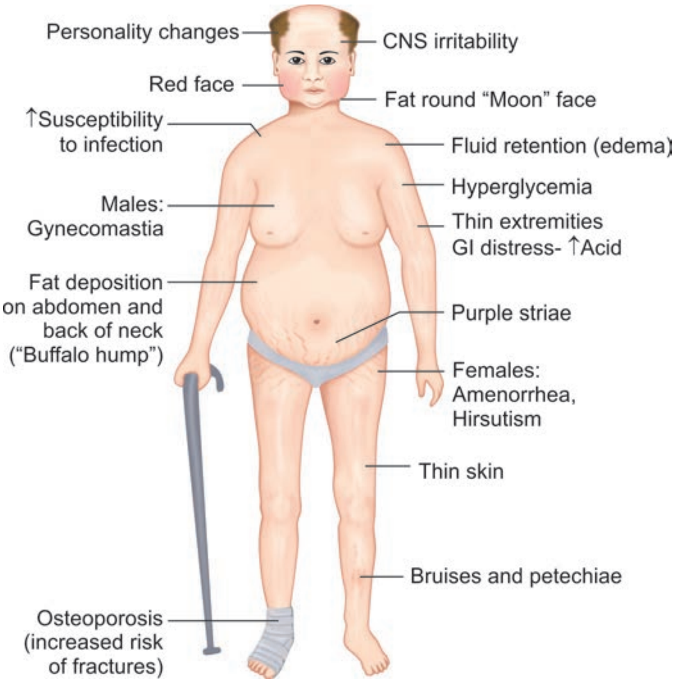
- Systemic fungal infections and tinea versicolor may develop in untreated patients.
- Higher risk of coronary artery disease and venous thrombosis.
- The predominant clinical features of Cushing's syndrome are those of glucocorticoid excess.
- Skin pigmentation occurs only with ACTH-dependent causes.
- Impaired glucose tolerance or frank diabetes is common, especially in the ectopic ACTH syndrome.
- Hypokalemia due to the mineralocorticoid activity of cortisol is common with ectopic ACTH secretion
- Proximal muscle weakness, sleep apnea, osteoporosis, and hypertension are common features of the disease.

Features of Cushing's Syndrome due to Ectopic ACTH Secretion

- Impaired glucose tolerance due to gluconeogenesis
- Hypokalemic alkalosis due to the mineralocorticoid activity of cortisol
- Skin pigmentation

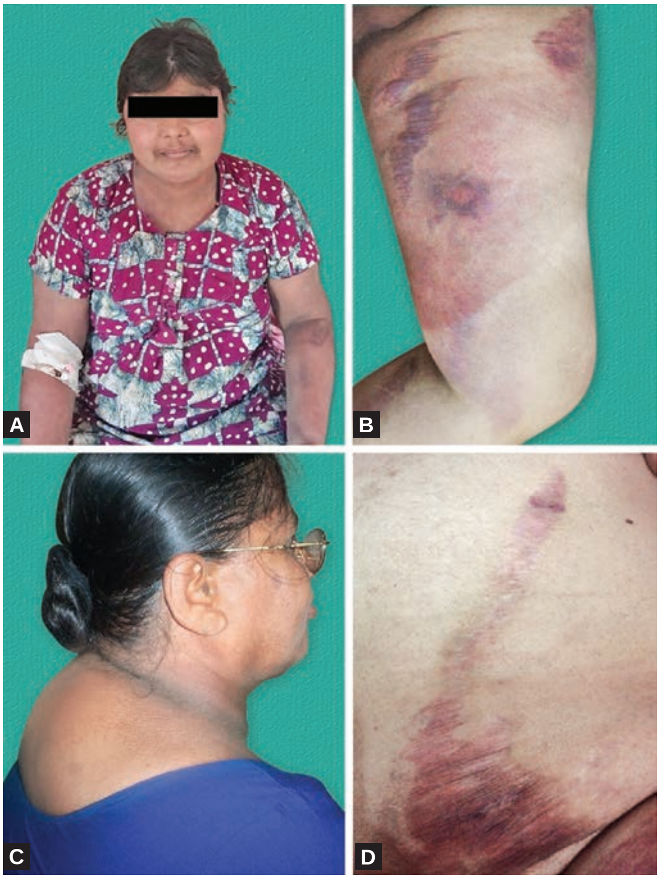
Investigations in Cushing's Syndrome (Flowchart 13.7)

- There are two phases of the investigation:
  i. **Confirmation** of the presence or absence of Cushing's syndrome.



Personality changes
CNS irritability
Red face
Fat round "Moon" face
↑Susceptibility to infection
Fluid retention (edema)
Hyperglycemia
Males: Gynecomastia
Thin extremities
GI distress- ↑Acid
Fat deposition on abdomen and back of neck ("Buffalo hump")
Purple striae
Females: Amenorrhea, Hirsutism
Thin skin
Bruises and petechiae
Osteoporosis (increased risk of fractures)

FIG. 13.15: Clinical features of Cushing's syndrome.



FIGS. 13.16A TO D: Features of Cushing's syndrome: (A) Cushing's habitus, obesity and moon facies; (B) Buffalo hump; (C and D) Pigmented striae.

TABLE 13.23: Clinical features of Cushing's syndrome (% prevalence).

Clinical features	***Cause***
General	
Weight gain/obesity (90%)	Accumulation of fat and retention of fluid
Central obesity ("lemon on match-stick")	Centripetal distribution of fat
Buffalo hump	Fat accumulation at the lower part of neck
Moon face	Rounded plethoric appearance
Hypertension (85%)	Increase in plasma volume and sodium retention
Skin	
Hirsutism (70–75%)	Increased secretion of adrenal androgen
Plethoric appearance	Thinning of the skin
Purplish striae over abdomen, buttocks and thighs	Thinning of the skin from collagen breakdown
Bruising	Thinning of blood vessels from collagen breakdown
Musculoskeletal	
Back pain (80%)	Osteopenia, osteoporosis and vertebral compression fractures
Muscle weakness (65%)	Proximal myopathy and **hypokalemia**. Loss of protein in muscle
Gonadal dysfunction	
Menstrual disorders (oligomenorrhea, amenorrhea) (70–85%)	Gonadal dysfunction
Decreased libido and impotence	
Neuropsychiatric	
Emotional lability, depression, euphoria, psychosis, irritability (85%)	
Metabolic	
Glucose intolerance (75%)	Metabolic abnormalities
Diabetes (20%)	
Hyperlipidemia (70%)	
Polyuria (30%)	
Kidney stones (15%)

Perform
MRI pituitary

(ACTH: Adrenocorticotropic hormone; CRH: Corticotropin-releasing hormone)

ii. **Differential diagnosis** of its cause (e.g., pituitary, adrenal or ectopic).
  - Most obese, hirsute, hypertensive patients do not have Cushing's syndrome.
  - Some cases of mild Cushing's have relatively subtle clinical signs.
  - Confirmation rests on demonstrating inappropriate cortisol secretion, not suppressed by exogenous glucocorticoids.
  - Random cortisol measurements are of no value.

- **Confirmatory tests to establish the presence of Cushing's syndrome** (2008 Endocrine Society Clinical Guidelines)
  - **48-hour low-dose dexamethasone test:** Normal individuals suppress plasma cortisol to <50 nmol/L. Patients with Cushing's syndrome fail to show complete suppression of plasma cortisol levels. This test is highly sensitive (>97%).

  - **24-hour urinary free cortisol measurements:** This is simple, but less reliable—repeatedly normal values (corrected for body mass) render the diagnosis most unlikely, but some patients with Cushing's have normal values on some collections (approximately 10%).
  - **Plasma cortisol levels:** In normal individuals, measurement of plasma cortisol levels at 8 AM and 12 midnight will show the lowest levels at midnight. This circadian rhythm is lost in Cushing's syndrome and the cortisol levels remain the same throughout the day. A midnight level below 1.8 µg/dL is normal, and has a high sensitivity for excluding Cushing's syndrome. However, it has a low specificity.
  - **Overnight 1 mg dexamethasone suppression test**
  - **Low dose dexamethasone suppression test**
  - **Late-night salivary cortisol** (two measurements)**:** It may be used as a screening test for Cushing's syndrome. Concentration of cortisol in saliva is highly correlated with free plasma cortisol, irrespective of salivary flow rates and stable at room temperature for 1 week.

TABLE 13.24: Interpretation of plasma ACTH level at 8 AM.

Level of plasma ACTH	*Probable source of ACTH as*
Normal levels (20–80 ng/L)	Pituitary
Intermediate values (80–300 ng/L)	Pituitary dependent disease or ectopic ACTH syndrome
Very high levels (>300 ng/L)	Ectopic ACTH syndrome
Low ACTH (<10 ng/L)	Adrenal tumors, macronodular adrenal hyperplasia or exogenous steroid administration

(ACTH: adrenocorticotropic hormone)

- **Tests that establish the cause of Cushing's syndrome:**
  - The first step in the evaluation is to distinguish whether hypercortisolism is **ACTH dependent or ACTH independent** (primary adrenal disease) by measuring ACTH, best performed by **two-site immunoradiometric assay (IRMA). Plasma ACTH level at 8 AM (Table 13.24)**.
  - **Imaging for ACTH Independent conditions (primary adrenal disease):** The next procedure after ruling out ACTH dependency is **CT** of the adrenal glands to look for adrenal mass.

    Note: Bilateral hyperplasia or bilateral macronodular adrenal hyperplasia may be seen with ACTH-dependent disease.
  - In patients with **ACTH dependent Cushing's**, the final stage of the diagnostic evaluation is to determine the source of ACTH by:
    - **High-dose dexamethasone suppression test (Table 13.25)**
      - 8 mg dexamethasone given orally at 11 PM, blood sample drawn at 8 AMthe next day for serum cortisol
      - Usually <5 µg/dL in most patients with Cushing's disease.
    - **CRH stimulation test:** Patients with Cushing's have ACTH and cortisol increases within 45 minutes after the IV administration of CRH.
      - Increased in pituitary dependent disease
      - Unchanged in ectopic ACTH syndrome and tumors of adrenal gland.
    - **Vasopressin stimulation test:** Stimulates ACTH in most patients with Cushing's disease.
    - **Petrosal venous sinus catheterization:** ACTH is measured in petrosal and peripheral venous plasma before and within 10 minutes after administration of CRH.
    - **Plasma potassium levels**
      - **Normal** in **pituitary dependant disease** and tumors of adrenal gland.
      - **Low** (3.5 mmol/L) in **ectopic ACTH syndrome**.
- **Other investigations**
  - **Biochemical investigations:** Blood glucose, cholesterol, and LDL may be raised.

TABLE 13.25: Tests in Cushing's syndrome.

Test and protocol	*Measure*	*Normal test result or positive suppression*	*Use and explanation*
Dexamethasone (for Cushing's)			
Overnight			
Take 1 mg on going to bed at 23:00 h	Plasma cortisol at 09:00 h next morning	Plasma cortisol <100 nmol/L	Outpatient screening test. Some 'false positives'
'Low-dose'			
0.5 mg 6-hourly Eight doses from 09:00 h on day 0	Plasma cortisol at 09:00 h on days 0 and +2	Plasma cortisol <50 nmol/L on second sample	For diagnosis of Cushing's syndrome
'High-dose' used in differential diagnosis			
2 mg 6-hourly Eight doses from 09:00 h on day 0	Plasma cortisol at 09:00 h on days 0 and +2	Plasma cortisol on day +2 less than 50% of that on day 0 suggests pituitary-dependent disease	Differential diagnosis of Cushing's syndrome Pituitary-dependent disease suppresses in about 90% of cases

- **Radiological investigations**
  - **Plain radiograph** of the skull. Radiograph of chest to detect lung cancer.
  - **CT scan** of anterior mediastinum, upper abdomen and pancreas to rule out tumors.
  - **CT/MRI** head and MRI abdomen.

Management

- **Exogenous Cushing's syndrome:** Taper and withdraw the glucocorticoid.
- **Cushing's disease**
  - **Treatment of choice:** Trans-sphenoidal adenomectomy when there is clear circumscribed microadenoma. In the remaining patients subtotal resection of anterior pituitary.
  - **Radiotherapy and radiosurgery:** For recurrent or residual ACTH-secreting tumors. External pituitary irradiation alone is slow-acting and useful in only 50–60% of cases.
  - **Medical therapy to reduce ACTH:** Needed when surgery is delayed, contraindicated, or unsuccessful. "Block and replace strategy" with **Ketoconazole** 200 mg TID and increased to 400 mg TID. If ketoconazole is unsuccessful in controlling cortisol secretion, it should be maintained at a total dose of 1,200 mg/day and **metyrapone** or **mitotane** (adrenolytic) should be added.
  - Pituitary targeted therapies have been tried. Only the somatostatin analog, **pasireotide**, and the dopamine agonist, **cabergoline** (and the combination of the two), have shown potential benefit.
  - **Bilateral adrenalectomy:**
    - Bilateral total adrenalectomy with lifelong daily glucocorticoid and mineralocorticoid replacement therapy is the final definitive cure.
    - Done if the diagnosis is uncertain.
    - Followed by pituitary irradiation with Yttrium-90 implantation to prevent the development of Nelson's syndrome.
    - Prednisolone and fludrocortisones should be given postoperatively for a variable length of time.
- **Adrenal tumors**
  - **Surgical resection**
    - **Adrenal adenomas:** Surgical removal. Postoperatively, prednisolone is given as a replacement therapy till the contralateral adrenal, hypothalamus, and pituitary recovers.
    - **Adrenal carcinomas:** Surgical resection, irradiation of tumor bed, and administration of adrenolytic drug (mitotane).
  - **Medical adrenalectomy:** Medications that inhibit steroidogenesis include ketoconazole, metyrapone, mitotane, aminoglutethimide, and octreotide.
- **Ectopic ACTH syndrome**
  - Surgical excision of benign tumors (e.g., bronchial carcinoid).
  - Radiotherapy and chemotherapy: For malignant tumors.
- Recurrent tumors may be treated with ketoconazole, metyrapone, or aminoglutethimide.

Nelson's Syndrome

Q. Write a short note on Nelson's syndrome.

- Nelson's syndrome is increased pigmentation (high levels of ACTH) associated with an enlarging pituitary tumor **postbilateral adrenalectomy.**
- It occurs in about 20% of cases after bilateral adrenalectomy for Cushing's disease.
- The syndrome is **rare** now that adrenalectomy is an uncommon primary treatment, and its incidence may be reduced by **pituitary radiotherapy** soon after adrenalectomy.
- **Treatment:** Nelson's adenoma may be treated by **pituitary surgery and/or radiotherapy.**

Hyperaldosteronism/Conn's Syndrome

Q. Write short essay on:

- Etiology, clinical features, diagnosis, and management of primary hyperaldosteronism.
- Conn's syndrome.

Excessive production of the aldosterone hormone is called hyperaldosteronism.

Classification

- **Primary hyperaldosteronism:** Develops due to an **abnormality in the zona glomerulosa** of the adrenal gland.

- **Secondary hyperaldosteronism:** Develops due to the **stimulation of aldosterone secretion** by angiotensin II following activation of renin-angiotensin system.

Primary Hyperaldosteronism

Etiology

- Adrenal adenoma **(Conn's syndrome)**
- Bilateral hyperplasia of zona glomerulosa/bilateral adrenal hyperplasia
- Idiopathic
- ACTH dependent (glucocorticoid-responsive or dexamethasone-suppressible): This is characterized by secretion of aldosterone under ACTH control. Therefore, treatment consists of **administration of glucocorticoids** to suppress release of ACTH.

Consequences

Excess secretion of aldosterone results in **sodium retention, potassium loss, and metabolic alkalosis.**

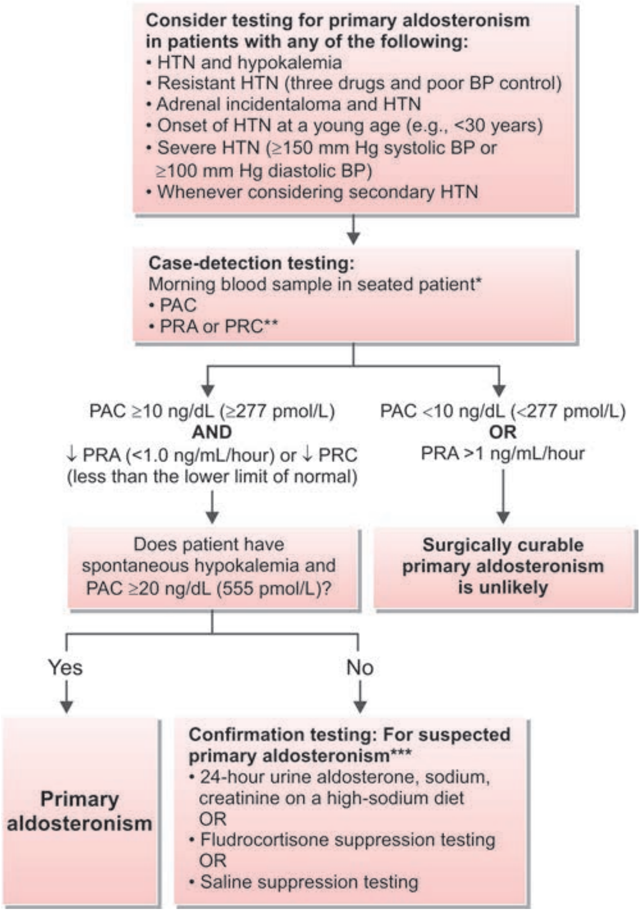
Clinical Features

- **Hypertension:** Most important clinical consequence of hyperaldosteronism.
- **Tetany** due to metabolic alkalosis
- **Muscle weakness** due to hypokalemia.
- **Polyuria and polydipsia** due to nephrogenic DI.

Investigations

- **Investigation for diagnosis (Flowchart 13.8)**
  - **Hypokalemia:** However, normal serum potassium does not exclude the diagnosis.
  - **Urinary potassium loss:** Levels >30 mEq/day during hypokalemia are inappropriate.
  - **Plasma aldosterone concentration (PAC):** Elevated (>10 ng/dL) and is not suppressed with 0.9% saline infusion (2 L over 4 hours, 8 AM to 12 PM, ideally when the patient is seated) or fludrocortisone administration.
  - **Suppressed plasma renin activity (PRA)** or immunoreactivity.
  - **PAC: PRA ratio** *[Plasma aldosterone: renin ratio (ARR)]*: Used as the screening test for primary hyperaldosteronism. A level above 20 is abnormal when plasma aldosterone is measured in ng/dL and PRA is measured in ng/mL/min.
  - **Confirmatory aldosterone suppression test**
    - **Oral salt loading test:** After controlling hypertension and hypokalemia, a high sodium diet (5,000 g sodium diet) should be given for 3 days. On the third day of this diet, a 24-hour urine specimen is collected for measurement of aldosterone, sodium, and creatinine. The 24-hour sodium excretion should be >4,600 mg to indicated proper sodium loading. Urine aldosterone excretion >12 µg/day indicates hyperaldosteronism.
    - **Saline infusion test:** IV administration of 2 L of 0.9% saline over 4 hours (from 8 AM to 12 PM). The

FLOWCHART 13.8: Case-detection testing for diagnosis of primary aldosteronism.



Consider testing for primary aldosteronism in patients with any of the following:
• HTN and hypokalemia
• Resistant HTN (three drugs and poor BP control)
• Adrenal incidentaloma and HTN
• Onset of HTN at a young age (e.g., <30 years)
• Severe HTN (≥150 mm Hg systolic BP or ≥100 mm Hg diastolic BP)
• Whenever considering secondary HTN
Case-detection testing:
Morning blood sample in seated patient*
• PAC
• PRA or PRC**
PAC ≥10 ng/dL (≥277 pmol/L)
AND
↓ PRA (<1.0 ng/mL/hour) or ↓ PRC (less than the lower limit of normal)
PAC <10 ng/dL (<277 pmol/L)
OR
PRA >1 ng/mL/hour
Does patient have spontaneous hypokalemia and PAC ≥20 ng/dL (555 pmol/L)?
Surgically curable primary aldosteronism is unlikely
Yes
No
Primary aldosteronism
Confirmation testing: For suspected primary aldosteronism***
• 24-hour urine aldosterone, sodium, creatinine on a high-sodium diet
OR
• Fludrocortisone suppression testing
OR
• Saline suppression testing

(HTN: hypertension; BP: blood pressure; PAC: plasma aldosterone concentration; PRA: plasma renin activity; PRC: plasma renin concentration)

* Patient out of bed for at least two hours and seated for at least 5 to 15 minutes before sample is drawn.

** Direct PRC can be measured instead of PRA. However, up-to-date authors prefer PRA. Refer to up-to-date topic on diagnosis of primary aldosteronism for interpretation of PRC cutoffs and normal values.

*** Oral sodium loading over three days is one confirmation test that many experts use. An alternative is the saline infusion test. Details of both are reviewed in the up-to-date topic on diagnosis of primary aldosteronism.

    PAC will fall below 5 ng/dL in healthy individuals, whereas values above 10 ng/dL are consistent with primary aldosteronism
    - **Oral captopril test:** In primary hyperaldosteronism, this test does not produce any significant decrease in PAC.

- **Investigation for differential diagnosis**
  - **CT/MRI scanning:** To detect adenoma and hyperplasia. Scanning of the adrenal with selenium-75 cholesterol to detect an adenoma.
  - **Adrenal vein catheterization:** To detect hypersecretion of aldosterone.
    - Unilateral hypersecretion in adenoma.
    - Bilateral hypersecretion in hyperplasia.
  - **Dexamethasone suppression**
    - Lowers plasma aldosterone transiently in adenoma.
    - Prolonged suppression in glucocorticoid sensitive hyperaldosteronism.
  - **Measurement of 18-OH-cortisol levels.**
    - Very high levels observed in adenomas and glucocorticoid-responsive hyperplasia.
    - Slightly raised in idiopathic hyperplasia.

Management of primary hyperaldosteronism

- Potassium (K^+) supplementation
- Unilateral disease: Laparoscopic adrenalectomy, bilateral if multiple tumors are present. Surgery is the definitive treatment in unilateral disease.
- In patients with bilateral hyperaldosteronism, mineralocorticoid therapy is administered.
- **Aldosterone antagonists: Spironolactone and eplerenone** are useful in patients where surgery cannot be performed. High dose of spironolactone (up to 400 mg/day) may be required. A few patients may develop gynecomastia with spironolactone and the incidence is lower with eplerenone. Amiloride (10–40 mg/day) may also be tried.

Secondary Hyperaldosteronism

Q. Write a short note on secondary hyperaldosteronism.

- Secondary hyperaldosteronism is **secondary to an extra-adrenal** cause.
- The aldosterone release occurs in response to **activation of the renin-angiotensin system**. It is characterized by *increased levels of plasma renin* that stimulates the zona glomerulosa.

Causes of Secondary Hyperaldosteronism (Table 13.26)

TABLE 13.26: Causes of secondary hyperaldosteronism.

Physiological	*Pathological*
➢ **Salt depletion:** Inadequate intake or excessive loss through kidney or gastrointestinal tract ➢ Pregnancy (due to estrogen-induced increases in plasma renin substrate)	➢ **Inadequate renal perfusion**: Excessive diuretic therapy, nephrotic syndrome, liver failure, congestive cardiac failure, Bartter's syndrome accelerated or malignant phase of hypertension, severe renal artery stenosis ➢ Renin-secreting renal tumor (very rare)

Adrenocortical Insufficiency

Classification and Causes (Box 13.15 and Table 13.27)

Q. Write a short essay/note on classification and causes of adrenocortical insufficiency.

Q. Write a short essay/note on etiology and clinical features of Addison's disease.

Adrenocortical insufficiency, or hypofunction, may be due to **primary adrenal disease** (primary hypoadrenalism) or **decreased stimulation of the adrenals** due to a deficiency of ACTH (secondary hypoadrenalism).

Box 13.15: Three-step process in the investigation of adrenocortical insufficiency.

- Confirm adrenal insufficiency by demonstrating inappropriately low cortisol secretion.
- Determine whether the cortisol deficiency is primary or central AI.
- Determine the cause of the underlying disorder.

Addison's Disease

Addison's disease or chronic adrenocortical insufficiency is an uncommon disorder resulting from **progressive destruction of the entire adrenal cortex.**

TABLE 13.27: Causes of adrenocortical insufficiency.

Primary (adrenal causes)		*Secondary (inadequate ACTH)*
➢ **Autoimmune adrenal insufficiency**: Isolated adrenal insufficiency, polyglandular autoimmune syndrome type 1 and 2 ➢ **Metastatic malignancy:** Lung, breast, stomach, colon carcinomas, or lymphoma ➢ **Adrenal hemorrhage** – Waterhouse–Friderichsen syndrome – Anticoagulation therapy ➢ **Infectious**: Tuberculosis, CMV, disseminated fungal infection (histoplasmosis, coccidioidomycosis), HIV, syphilis and African trypanosomiasis ➢ **Adrenal infarction:** APLA, SLE	➢ Adrenoleukodystrophy and adrenomyeloneuropathy ➢ **Infiltrative disorders**: Amyloidosis, hemochromatosis, and sarcoidosis ➢ Bilateral adrenalectomy ➢ Congenital adrenal hyperplasia ➢ Familial glucocorticoid deficiency and hypoplasia ➢ **Drugs:** Ketoconazole, fluconazole, metyrapone, aminoglutethimide, mitotane, etomidate, rifampin, and cyproterone acetate ➢ Kearns–Sayre syndrome	➢ Exogenous glucocorticoid therapy ➢ Hypopituitarism: Selective removal of pituitary ➢ Pituitary apoplexy ➢ Granulomatous disease of pituitary (tuberculosis, sarcoidosis, and eosinophilic granuloma) ➢ Secondary tumor deposits in pituitary (breast and bronchus) ➢ Postpartum pituitary infarction (Sheehan's syndrome) ➢ Pituitary irradiation

(ACTH: Adrenocorticotropic hormone; APLA: Antiphospholipid antibody; CMV: Cytomegalovirus; HIV: Human immunodeficiency virus; SLE: Systemic lupus erythematosus)

Clinical Features of Addison's Disease (Table 13.28 and Figs. 13.17A and B)

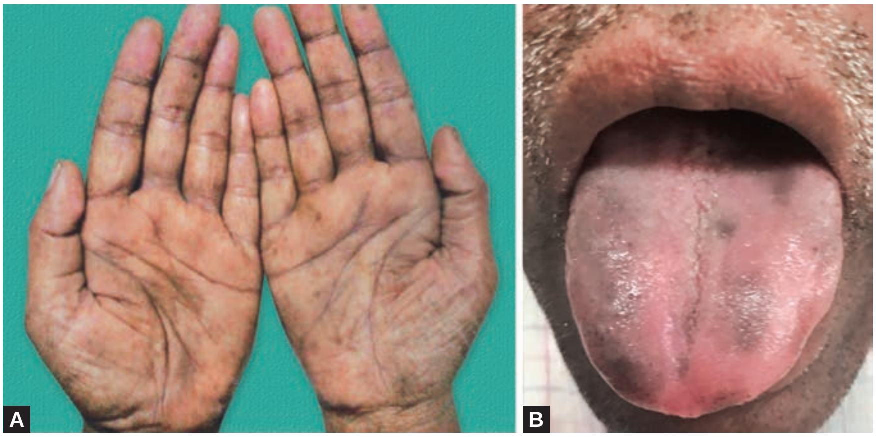
Q. Write a short essay/note on major clinical signs of Addison's disease.

- Clinical features are produced due to the **deficiency of glucocorticoid, mineralocorticoid, and androgen** as well as **excess of ACTH.**
- Fatigue and weight loss are the most prominent symptoms.
- Primary adrenal failure may present.
  - **Acute:** Hypotension and acute circulatory failure with shock out of proportion to severity of current illness, dehydration, an "acute abdomen", unexplained hypoglycemia, and unexplained fever (Addisonian crisis)
  - **Chronic**: Vague features of ill health, sometimes including gastrointestinal symptoms, features suggestive of postural hypotension and salt craving.
- Skin pigmentation is nearly always present in primary adrenal insufficiency (but not in secondary).

TABLE 13.28: Clinical features of adrenocortical insufficiency.

Glucocorticoid deficiency	*Mineralocorticoid deficiency*	*Adrenal androgen deficiency*	*ACTH excess*
Fasting hypoglycemia	Hypotension	Decreased axillary hair in females	Pigmentation of exposed areas, pressure areas (elbows, knees and knuckles, palmar creases, mucous membranes, conjunctive and recently acquired scars, perineum, axillae and areolae of breasts) [increased production of pro-opiomelanocortin (POMC), that is cleaved into ACTH and melanocyte-stimulating hormone (MSH)]
Increased insulin sensitivity	Dizziness	Decreased pubic hair in females	
Muscle weakness	Salt craving	Loss of libido in females	
Morning headache	Weight loss and anorexia	Asymptomatic-during prepuberty	
Fatigue, malaise, weakness, weight loss, anorexia, nausea, vomiting, diarrhea or constipation, and postural hypotension	Electrolyte anomalies (hyponatremia, hyperkalemia, and metabolic acidosis)		

(ACTH: Adrenocorticotropic hormone)



FIGS. 13.17A AND B: (A) Pigmentation of palms; (B) Oral pigmentation in Addison's disease.

- **Cardinal features of Addison's disease:** Hypotension, pigmentation and previous history of acute adrenal crisis following stress, or slow recovery from illness.
- **Other autoimmune diseases associated with Addison's disease:** Hashimoto's thyroiditis, primary atrophic hypothyroidism, pernicious anemia, type 1 diabetes mellitus, primary ovarian failure, and hypoparathyroidism.
    - **Type I polyglandular autoimmune syndrome** is the combination of adrenal insufficiency, hypoparathyroidism, and chronic mucocutaneous candidiasis.
    - **Type II polyglandular autoimmune syndrome/Schmidt syndrome** is the association of Addison's disease and Hashimoto's thyroiditis.

Investigations

Q. Write a short essay/note on biochemical abnormality in Addison's disease.

- **Early morning (6 AM) cortisol level**
    - Normally, levels are 10–20 μg/dL
    - Levels <3 μg/dL is suggestive of adrenal insufficiency
    - Levels >11 μg/dL exclude AI
    - Random cortisol in ill patient 20 μg/dL reassuring.
- **Morning salivary cortisol concentration**
    - Levels below 1.8 ng/mL is highly suggestive of adrenal insufficiency
    - Levels above 5.8 ng/mL rule out adrenal insufficiency
- **Plasma ACTH level:** Elevated in adrenal insufficiency.
- **ACTH stimulation test:** There is failure of rise in plasma cortisol level following the administration of 0.25 mg (standard high dose test) of synthetic ACTH (cosyntropin).
    - Low dose test (1 μg)
        - Baseline and 30-minute cortisol levels
        - More physiological ACTH level/stimulation
        - Useful in central AI
        - Useful for assessing recovery after chronic steroid treatment.
    - High dose (250 μg) test
        - Baseline, 30- and 60-minute levels
        - Stronger stimulation than 1 μg test.
- **Metyrapone test:** Useful to detect partial ACTH deficiency and partial secondary adrenal insufficiency.
- **Insulin-induced hypoglycemia test:** Insulin at a dose of 0.15 U/kg is administered to achieve hypoglycemia of 35 mg/dL or less. Cortisol levels are measured at 0, 30, and 45 minutes.
- **Corticotropin-releasing hormone test:** To differentiate between secondary and tertiary adrenal insufficiency.
- **Other investigations:** PRA is high and plasma aldosterone levels are low or normal.
- **Radiograph:** In patients with tuberculous adrenalitis: Chest radiograph may show evidences of pulmonary tuberculosis and plain radiograph of abdomen, CT scan, and MRI scan may show calcification in the adrenal gland.
- **Adrenal autoantibodies:** ACA—adrenal cortex antibody and anti-21-OH-hydroxylase antibody.
- **Hypoglycemia**, elevated blood urea, **hyponatremia**, and **hyperkalemia**.
- **Peripheral blood:** Mild anemia and mild eosinophilia.
- **Central AI**: Evaluate for secretion of other pituitary hormones.

Management of primary adrenal insufficiency

- **Acute treatment:**
    - Normal saline for volume resuscitation
    - Look for/treat hypoglycemia by 25% dextrose
    - **Steroids:**
        - Loading dose: 50–100 mg/m^2 **hydrocortisone** IV/IM
        - Continue hydrocortisone with 50–100 mg/m^2/day, divided 6th or 8th hourly
- **Long-term treatment:**
    - Daily glucocorticoid replacement (hydrocortisone): 10–15 mg/m^2/day in divided doses.
    - Daily mineralocorticoid replacement: Fludrocortisone 0.05–0.2 mg daily
    - Relative steroid potencies **(Table 13.29)**

- **Stress conditions**
  - Primary goal is to avoid serious consequences of an adrenal crisis
  - Always wear identification
  - Illness:
    - Minor stress (e.g., sore throat, rhinorrhea, temperature <38°C) may not require increase in dose.
    - Moderate stress (e.g., severe URTI)—double the glucocorticoid (GC) replacement dose
    - Major stress (e.g., T >38°C and/or vomiting), three to four times the GC replacement dose.
  - Surgery:
    - During general anesthesia, ± surgery, the GC requirement increases greatly.
    - Dose equivalent to 100–150 mg hydrocortisone for major surgical procedures in divided doses.
    - Stress dosing is generally continued until the patient can tolerate oral intake, is afebrile, and is hemodynamically stable.
- Tuberculous adrenalitis causing Addison's disease is treated with **antituberculous chemotherapy.**

Acute Adrenal Crisis/Addisonian Crisis

Q. Write a short note on acute adrenal crisis.

- Acute adrenal crisis is a state of **acute adrenocortical insufficiency** and occurs in patients with **Addison's disease** who are exposed to the **stress** of infection, trauma, surgery, or dehydration due to salt deprivation, vomiting, or diarrhea.
- **Other causes:** Acute adrenal crisis can also develop after:
  - Bilateral adrenal infarction
  - Bilateral adrenal hemorrhage: Adrenal hemorrhage and often death may occur following meningococcemia (**Waterhouse-Friderichsen syndrome**).
- It is rare with secondary adrenal insufficiency.

TABLE 13.29: Anti-inflammatory action of steroids compared to hydrocortisone.

Type of steroid	*Activity*
Short-acting	
Hydrocortisone	1
Cortisone acetate	0.8
Intermediate-acting	
Prednisone	4
Prednisolone	4
Methylprednisolone	5
Triamcinolone	5
Long-acting	
Dexamethasone	30
Betamethasone	30

Clinical Features

- **Major manifestations:**
  - Shock (out of proportion to severity of illness)
  - **Nonspecific symptoms:** Weakness, fatigue, lethargy, anorexia, nausea, vomiting, abdominal pain, confusion or coma.
  - Abdominal tenderness "acute abdomen" and unexplained fever.
- **Crisis in patients with long-standing adrenal insufficiency:** Shows features of chronic adrenal insufficiency and may show hyperpigmentation (due to chronic ACTH hypersecretion), weight loss, and serum electrolyte abnormalities.

Laboratory Findings

- Hyponatremia
- Hyperkalemia
- Hypercalcemia
- Azotemia
- Lymphocytosis
- Eosinophilia
- Hypoglycemia.

Equivalent doses of glucocorticoids (Table 13.30)

- Compared to hydrocortisone, prednisolone has only 25% of mineralocorticoid activity (**Table 13.31**).
- Both dexamethasone and betamethasone have negligible mineralocorticoid activity.

TABLE 13.30: Equivalent doses of glucocorticoids (anti-inflammatory potency).

Hydrocortisone (cortisol)	20 mg	Methylprednisolone	4 mg
Cortisone acetate	25 mg	Betamethasone	0.75 mg
Prednisolone	5 mg	Dexamethasone	0.75 mg

Management

- Establish IV access with a large bore needle.
- Withdraw blood for serum electrolytes, glucose and routine plasma cortisol and ACTH. **Do not wait for results.**
- IV infusion of 2–3 L normal saline bolus. Avoid iatrogenic fluid overload.
- IV **hydrocortisone** 100 mg, followed by 50 mg IV every 6 hours OR 200 mg/day IV infusion.
- After initial stabilization, continue IV NS at a slower rate for next 24–48 hours.
- Search and manage possible precipitating cause.
- In case patient is not a known case of AI, do short ACTH stimulation test.
- Determine the type of AI.
- Taper parenteral glucocorticoid over 1–3 days to oral maintenance dose.
- Start mineralocorticoid replacement with **fludrocortisone** 0.1 mg by mouth daily when saline infusion is stopped.

Steroid Therapy

Common Indication and Contraindications of Steroids (Table 13.31)

Q. Write a short note on the use and abuse of steroids/the present role of steroid therapy.

TABLE 13.31: Common indications and contraindications of steroids.

Common indications of steroids	
➢ Bronchial asthma ➢ Raised intracranial tension ➢ Cerebral edema ➢ Connective tissue diseases—rheumatoid arthritis and systemic lupus erythematosus ➢ Nephrotic syndrome ➢ Adrenal insufficiency ➢ Shock and septicemia ➢ Transplant rejection and graft versus host disease	➢ Leukemia, lymphoma, ➢ As an adjunct in chemotherapy ➢ Carditis (e.g. rheumatic carditis) ➢ Demyelinating diseases ➢ Tuberculosis of pericardium and tuberculous meningitis ➢ Bone marrow transplantation ➢ Psoriasis and inflammatory bowel disease ➢ Eye conditions: Scleritis and chorioretinitis
Common contraindications of steroids	
➢ Active tuberculosis ➢ Peptic ulcer ➢ Diabetes	➢ Uncontrolled hypertension ➢ Active infection

Side Effects of Corticosteroids Therapy (Table 13.32)

Q. Write a short note on the complications of corticosteroid therapy.

Measures to Reduce the Side Effects of Corticosteroids Therapy

Q. Write a short note on measures to minimize the side effects of corticosteroid.

Side effects of steroids can be reduced by administering them with the following rules:

- Lowest required dose
- Only under medical supervision
- On alternate days rather than daily
- Monitor intake of calories to prevent weight gain
- As a single dose than in divided doses
- Reduce intake of sodium
- In the morning
- Use H_2 receptor blockers or proton-pump inhibitors
- For the shortest required duration
- Provide high calcium intake and pump inhibitors
- For indications only
- Use bisphosphonates

Waterhouse–Friderichsen Syndrome

Q. Write a short note on Waterhouse–Friderichsen syndrome.

- It is characterized by an **acute hemorrhagic** infarction **(destruction) of both the adrenal glands** and is usually associated with fulminant **meningococcal septicemia**.
- It produces cutaneous petechiae, vasomotor collapse, and shock.
- Can occur at any age but is more common in children.
- **Abrupt in onset** and profound prostration occurs within a few hours.
- It produces petechiae, purpuric lesion, and hemorrhage into the skin.

TABLE 13.32: Adverse effects of glucocorticoids.

Immune system	*Bones*	
➢ Increased susceptibility to infections, reactivation of latent tuberculosis ➢ Lymphopenia ➢ Suppression of inflammation impaired wound healing ➢ Suppression of delayed hypersensitivity reaction	➢ Osteoporosis ➢ Avascular necrosis ➢ Bone pains ➢ Fracture	
Gastrointestinal tract	***Endocrine***	
➢ Gastric erosions ➢ Peptic ulceration ➢ Masked perforation ➢ Hemorrhage from stomach and duodenum ➢ Pancreatitis	➢ Growth retardation ➢ Menstrual irregularities ➢ Hypothalamic-pituitary-adrenal axis suppression ➢ Impotence ➢ Acute adrenal insufficiency, Cushingoid features	
Skin	***Metabolic***	
➢ Acne rubeosis steriodica ➢ Hirsutism ➢ Striae ➢ Ecchymoses ➢ Thin and fragile skin ➢ Panniculitis (on withdrawal)	➢ Glucose intolerance or frank diabetes mellitus ➢ Weight gain ➢ Hyperlipidemia ➢ Hypokalemia ➢ Alkalosis ➢ Fluid and salt retention ➢ Negative nitrogen balance-muscle wasting	
Psychiatric	***Cardiovascular***	
➢ Depression ➢ Insomnia ➢ Euphoria ➢ Steroid psychosis	➢ Hypertension ➢ Fluid retention ➢ Accelerated atherosclerosis ➢ Ischemic heart disease (IHD)	
Muscles	***Eye***	***Neurological***
Myopathy	➢ Cataract ➢ Glaucoma	Pseudotumor cerebri

Management

Prompt recognition and appropriate therapy, intravenous fluids, high dose antibiotics (penicillin, cephalosporins, and sulfonamides), vasopressors, inotropes, plasma transfusion, steroids must be instituted immediately, or death follows within hours to a few days due to cardiac and/or respiratory failure.

Pheochromocytoma

Q. Write a short essay/note on clinical features, diagnosis, and treatment of pheochromocytoma.

- Pheochromocytoma is a very rare tumor of the sympathetic nervous system composed of chromaffin cells that secretes catecholamines.
- Important because they are a rare cause of surgically correctable hypertension.
- **Paraganglioma:** Pheochromocytomas that develop in **sympathetic ganglia** are known as paragangliomas.
- It arises from both sympathetic and parasympathetic paraganglia, located anywhere from the base of the skull to the pelvis.
- Paragangliomas typically occur in the head and neck but are also found in the thorax, pelvis, and bladder.
- Traditionally, the features of pheochromocytomas have been summarized by the "rule of 10s" **(Box 13.16)**.
- **Neurofibromatosis type 1 (Von Recklinghausen's disease)** is associated with an increased incidence of pheochromocytoma.

Box 13.16: Rule of 10s'for pheochromocytoma.

10%	Extra-adrenal (closer to 15%)
10%	Abdominal
10%	Occur in children
10%	Familial (now modified as closer to 25%)
10%	Sporadic are bilateral or multiple (more if familial)
10%	Not associated with hypertension
10%	Malignant
10%	Discovered incidentally
10%	Recur (more if adrenal)

TABLE 13.33: Familial pheochromocytoma.

MEN 2a	50% pheochromocytoma (usually bilateral), medullary carcinoma of thyroid, and hyperparathyroidism
MEN 2b	50% pheochromocytoma (usually bilateral), medullary carcinoma of thyroid, mucosal neuroma, and marfanoid habitus
Von Hippel–Landau	50% pheochromocytoma (usually bilateral), retinoblastoma, cerebellar hemangioma, nephroma, and renal/pancreas cysts
NF1 (Von Recklinghausen's)	2% pheochromocytoma (50% if NF-1 and HTN) Café-au-lait spots, neurofibroma, and optic glioma
Familial paraganglioma	
Familial pheochromocytoma and islet cell tumor	
Other: Tuberous sclerosis, Sturge–Weber, ataxia-telangiectasia, Carney's triad (pheochromocytoma, gastric leiomyoma, and pulmonary chondroma)	

(HTN: Hypertension; NF-1: Neurofibromatosis type 1

Clinical Features (Table 13.33)

- The classic triad of symptoms in patients with a pheochromocytoma consists of episodic headache, sweating, and tachycardia
- **5 Ps:** *Pressure (90%), Pain (80%), Perspiration (70%), Palpitations (65%), and Pallor (42%)*
- **Paroxysmal hypertension: Most Common sign.**
  - Characterized by episodes of **pallor or flushing, headache sweating, palpitations, and anxiety** (fear of death).
  - Paroxysms last 10–60 minutes duration, daily to monthly
  - **Paroxysms are spontaneous or precipitated by:**
    - Diagnostic procedures, intra-arterial contrast
    - Drugs (opioids, unopposed beta-blockade, anesthesia induction, histamine, ACTH, glucagon, and metoclopramide)
    - Strenuous exercise, movement that increases intra-abdominal pressure (lifting and straining)
    - Micturition (bladder paraganglioma)
- Sustained hypertension is more common than paroxysmal hypertension.
- **Complications of hypertension:** Stroke, myocardial infarction and left ventricular failure. Rarely, pheochromocytoma is associated with cardiomyopathy attributed to catecholamine excess.
- **Gastrointestinal symptoms:** Abdominal pain, vomiting, constipation, and weight loss.
- **Hypercalcemia:** Observed in associated MEN2 hyperparathyroidism
- **Mild glucose intolerance:** Lipolysis and weight-loss.

Investigations (Table 13.34 and Flowchart 13.9)

- **Plasma metanephrine** is the most sensitive test.
- **Other investigations**
  - Fractionated metanephrines and catecholamines in a 24-hour urine collection

- **Chromogranin A:** It is a major secretory protein present in the soluble matrix of chromaffin granules and is elevated.
- **Provocative** (glucagon provocative test) and adrenolytic (clonidine, phentolamine test) tests: Rarely necessary.
- **CT/MRI scan:** To localize tumor.
- **Scintigraphy:** Useful for localization of tumor and includes:
  - MIBG (^{123}I-labeled meta-iodobenzylguanidine) scintigraphy
  - Somatostatin receptor scintigraphy using 111indium-labeled diethylenetriaminepentaacetic acid octreotide scan.
  - (^{18}F) fluro-dihydroxyphenylalanine (DOPA) PET scan.
- **Plasma noradrenaline:** Selective venous sampling and estimation of plasma noradrenaline level may be useful in localizing the tumor in difficult cases.

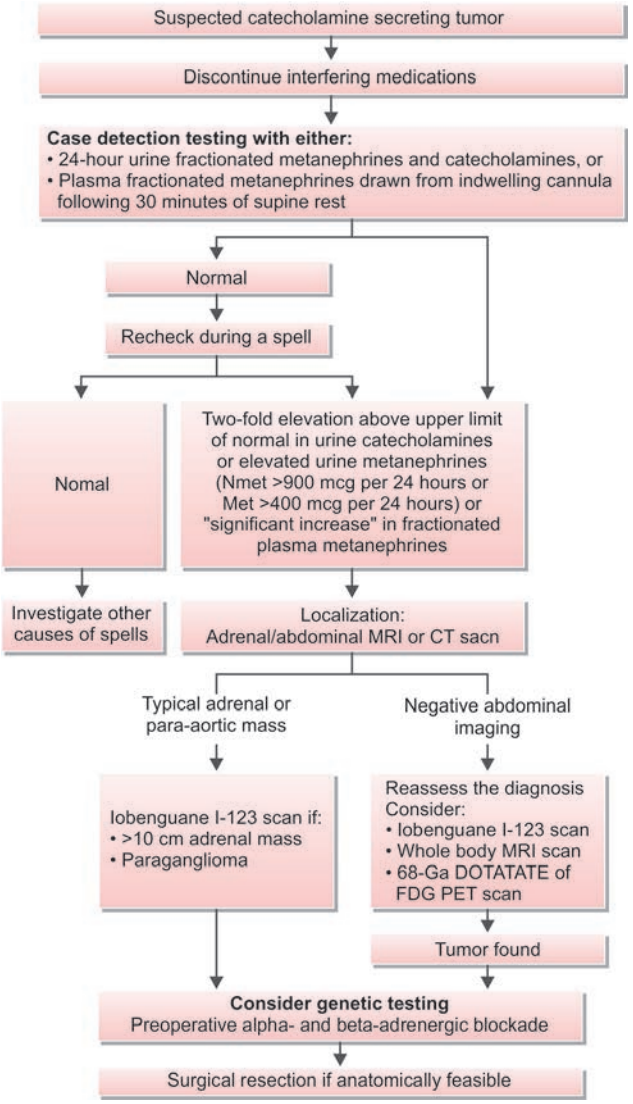
TABLE 13.34: Laboratory findings in pheochromocytoma.

Investigations	*Level*	*Sensitivity*	*Specificity*
24-hour urine vanillylmandelic acid (VMA)	Raised	63%	94%
24-hour urine metanephrines and normetanephrines	Raised	76%	94%
24-hour urine free catecholamines	Raised	83%	88%
24-hour urine free catecholamines + metanephrines	Raised	90%	98%
Plasma catecholamines	Raised	85%	80%
Plasma metanephrines	Raised	99%	89%

Management

- **Excision of the tumor** is the main treatment.
- Special care has to be taken preoperatively, intraoperatively, and postoperatively.
- **Preoperative preparation regimens**
  - Combined α **+** β**-blockade** to be given at least 2 weeks preoperatively to control the hypertension. Antihypertensive agents used are: **phenoxybenzamine** (preferred drug for preoperative preparation). Initial dose is 10–20 mg in divided doses every 2–3 days as needed, final dose will be 20–100 mg/day. Other drugs used are selective α1-blocker (prazosin, terazosin, or doxazosin).
  - Beta-blockers should never be started first. Drugs such as **propranolol** or **metoprolol** are used. Dose should be adjusted to control tachycardia. Typical maximum doses in this setting are 120 mg of propranolol or 200 mg of metoprolol.
  - **High sodium diet**—patients are encouraged to start a diet high in sodium content (>5,000 mg daily) on the second or third day because of the catecholamine-induced volume contraction and the orthostasis associated with alpha-adrenergic blockade.
  - **If uncontrolled add:**
    - Metyrosine
    - Calcium channel blockers: **Nicardipine** and **amlodipine** are most commonly used in this setting; starting dose of nicardipine is 30 mg twice daily of the sustained-release preparation and the starting dose of amlodipine is 2.5 or 5 mg administered once daily.
    - Avoid diuretics as ECF volume is already contracted.
- **Intraoperative** blood pressure needs to carefully monitored and controlled.
- **Postoperative** hypotension can be avoided by adequate fluid replacement and hypoglycemia (10–15% of patients) due to removal of catecholamine suppression of insulin secretion by glucose infusion. Postoperatively patients may become hypertension free.
- **If tumor cannot be excised:**
  - Long-term treatment with α- and β-adrenoreceptors blocking drugs (phenoxybenzamine and propranolol, or labetalol) is advocated.
  - β-blockers should never be given alone.
  - Patients can also be subjected to nuclear medicine treatment.

FLOWCHART 13.9: Evaluation and treatment of catecholamine producing tumors.



Suspected catecholamine secreting tumor
Discontinue interfering medications
Case detection testing with either:
• 24-hour urine fractionated metanephrines and catecholamines, or
• Plasma fractionated metanephrines drawn from indwelling cannula following 30 minutes of supine rest
Normal
Recheck during a spell
Nomal
Two-fold elevation above upper limit of normal in urine catecholamines or elevated urine metanephrines (Nmet >900 mcg per 24 hours or Met >400 mcg per 24 hours) or "significant increase" in fractionated plasma metanephrines
Investigate other causes of spells
Localization: Adrenal/abdominal MRI or CT sacn
Typical adrenal or para-aortic mass
Negative abdominal imaging
Iobenguane I-123 scan if:
• >10 cm adrenal mass
• Paraganglioma
Reassess the diagnosis
Consider:
• Iobenguane I-123 scan
• Whole body MRI scan
• 68-Ga DOTATATE of FDG PET scan
Tumor found
Consider genetic testing
Preoperative alpha- and beta-adrenergic blockade
Surgical resection if anatomically feasible

(Nmet: Normetanephrine; Met: Metanephrine; MRI: Magnetic resonance imaging; CT: Computed tomography; PET: Positron emission tomography)

Source: Modified and reprinted with permission from: Young WF Jr. Pheochromocytoma: 1926–1993. In: Trends in Endocrinology and Metabolism. Vol 4. Champaign, IL: Elsevier. Science, Inc; 1993:122.

TABLE 13.35: Specific abnormalities of sexual development.

First trimester	➢ Ambiguous genitalia in deficient testosterone production ➢ Female external genitalia in complete lack of testosterone production Incomplete testosterone deficiency or androgen action causes partial virilization
Third trimester	➢ Micropenis ➢ Bilateral cryptorchidism
Prepubertal	Failure to undergo/complete puberty
Adult	Decreased energy/libido Infertility

TABLE 13.36: Androgen deficiency symptoms.

Musculoskeletal	➢ Decreased vigor and physical energy ➢ Diminished muscle strength
Sexuality	➢ Decreased interest in sex ➢ Reduction in frequency of sexual activity ➢ Poor erectile function/arousal ➢ Loss of nocturnal erections ➢ Reduced quality of orgasm ➢ Reduced volume of ejaculate
Mood disorder and cognitive function	➢ Irritability and lethargy ➢ Decreased sense of well-being, lack of motivation ➢ Low mental energy, difficulty with short-term memory ➢ Depression ➢ Low self-esteem, insomnia, and nervousness
Vasomotor and nervous	Hot flushes and sweating

GONADAL DISORDERS (TABLES 13.35 AND 13.36)

Male Hypogonadism

- **Primary hypogonadism,** if the serum testosterone and/or the sperm count are below normal and the serum LH and/or FSH concentrations are above normal.
- **Secondary hypogonadism,** if the serum testosterone concentration and/or the sperm count are below normal and the serum LH and/or FSH concentrations are normal or low.

Q. **Discuss the causes and approach to male hypogonadism.**

Classification and Causes of Male Hypogonadism (Table 13.37)

TABLE 13.37: Classification and causes of male hypogonadism.

Hypothalamic-pituitary disorders	*Defects in androgen action*
➢ Panhypopituitarism ➢ LH and FSH deficiency – With normal sense of smell – With hyposmia or anosmia (Kallmann's syndrome) – With complex neurologic syndromes ➢ Prader–Willi syndrome < Laurence–Moon, Bardet–Biedl syndromes < Möbius' syndrome < Lowe's syndrome ➢ Klinefelter's syndrome ➢ Other chromosomal defects (XX male, XY/XXY, XX/XXY, XXXY, and XYY) ➢ Bilateral anorchia (vanishing testes syndrome) ➢ Cryptorchidism ➢ Noonan's syndrome ➢ Myotonic dystrophy ➢ Adult seminiferous tubule failure < adult ➢ Leydig cell failure ➢ Secondary hypogonadism ➢ Hyperprolactinemia ➢ Glucocorticoid treatments ➢ Chronic and systemic illness	➢ Complete androgen insensitivity (testicular feminization) ➢ Incomplete androgen insensitivity ➢ Anorexia nervosa ➢ Diabetes mellitus ➢ Hepatic cirrhosis ➢ HIV ➢ Mumps ➢ Obesity ➢ Malignant tumors of testes ➢ Infiltrative diseases—hemochromatosis ➢ Chronic orchitis: TB, leprosy, and syphilis ➢ Pituitary apoplexy ➢ Trauma and testicular torsion ➢ Idiopathic

Physical Signs

- Diminished muscle mass
- Loss of body hair
- Abdominal obesity
- Gynecomastia
- Testes frequently normal, occasionally small

Prepubertal onset: Eunuchoidism

- Lack of adult male hair distribution
  - Sparse axillary and pubic hair
  - Lack of temporal hair recession
- High-pitched voice
- Infantile genitalia: Small penis, testes, and scrotum
- Fat deposition in pectoral, hip, thigh, and lower abdomen

- Eunuchoidal proportion
    - Arm span > height > 5 cm
    - Upper/lower segment ratio < 1

Investigations

- Serum testosterone: 8.00 AM
- Serum FSH and LH
- **Semen analysis:** Normally, >40% of the sperm ejaculated are motile, >32% have rapid forward progression, and >4% have normal morphology.
- **Others:** Peripheral leukocyte karyotype, other pituitary hormones, serum prolactin, iron saturation, and MRI brain.

Treatment of Primary Hypogonadism

- Testosterone replacement for men who are hypogonadal only with signs and symptoms with subnormal morning serum testosterone.
- Treatment of the underlying disease

Q. Write a short note on testosterone replacement.

Testosterone replacement

- **Transdermal testosterone** is started in gel form.
- Intramuscular preparations—**testosterone enanthate** (100–200 mg IM q 2 weeks)
    - Oral agent—**testosterone undecanoate** (initial 120–160 mg/day in 2 divided doses for 2–3 weeks; usual maintenance dose: 40–120 mg/day), however parenteral formulations are preferred as adverse effects of oral preparation are hypertension and cardiovascular events.
    - **Undesirable effects:** BPH, prostatic cancer, dyslipidemia, polycythemia, and transaminitis.
- **Treatment of secondary hypogonadism**
    - GnRH pulsatile infusion
    - hCG

Impotence

Q. What is impotence? Discuss briefly.

- **Definition: Male sexual dysfunction** is termed "impotence".
- **Manifestations:**
    - Loss of desire
    - Inability to obtain and maintain erection
    - Premature ejaculation
    - Absence of emission
    - Inability to achieve orgasm.

Causes of Male Infertility (Box 13.17)

Erectile impotence may be due to various causes, but majority are of psychological origin. In each case of erectile impotence, it is necessary to rule out the organic causes (**Table 13.38**).

Gynecomastia

Q. PA31.4 Enumerate and describe the etiology, hormonal dependency and pathogenesis of gynecomastia.

Q. Write a short note on gynecomastia.

- It is clinically defined as the presence of a rubbery or firm mass concentrically extending from the nipples in a male secondary to proliferation of both **stromal and epithelial component of the glands**.
- It must be differentiated from pseudogynecomastia **(lipomastia)** seen in obese individuals, which is characterized by **only fat deposition** without glandular proliferation.

Box 13.17: Causes of male infertility.

- **Endocrine**
    - Hypothalamic-pituitary disorders
    - Testicular disorders
    - Defects of androgen action
    - Hyperthyroidism
    - Hypothyroidism
    - Adrenal insufficiency
    - Congenital adrenal hyperplasia
- Systemic illness
- Defects in spermatogenesis
- Immotile cilia syndrome
- Drug-induced
- **Ductal obstruction**
    - Congenital
    - Acquired seminal vesicle disease
    - Prostatic disease
    - Varicocele
- Retrograde ejaculation
- Antibodies to sperm or seminal plasma
- Anatomic defects of the penis
- Poor coital technique
- Sexual dysfunction
- Idiopathic

TABLE 13.38: Organic causes of erectile dysfunction.

Neurologic	***Urogenital***	***Drugs***
Anterior temporal lobe lesions	Trauma	Antiandrogens
Spinal cord lesions	Castration	Estrogens
Autonomic neuropathy	Priapism	5-α-reductase inhibitors
Vascular	Peyronie's disease	GnRH agonists
Leriche's syndrome	***Systemic illness***	Antihypertensives
Pelvic vascular insufficiency	Cardiac insufficiency	Diuretics
Sickle cell disease	Cirrhosis	Psychotropic agents
Endocrine	Uremia	Tranquilizers
Diabetes mellitus	Respiratory insufficiency	Monoamine oxidase inhibitors
Hypogonadism	Lead poisoning	Tricyclic antidepressants
Hyperprolactinemia	***Postoperative***	Tobacco
Adrenal insufficiency	Aortoiliac or aortofemoral reconstruction	Alcohol
Feminizing tumors	Lumbar sympathectomy	Cocaine
Hypothyroidism	Perineal prostatectomy	
Hyperthyroidism	Retroperitoneal dissection	

TABLE 13.39: Causes of gynecomastia.

Physiologic		***Neoplasms***
➢ Neonatal ➢ Pubertal ➢ Involutional		➢ Testicular germ cell ➢ Leydig cell tumors ➢ hCG-secreting nontrophoblastic neoplasms
Drug-induced		***Systemic diseases***
➢ Androgens and anabolic steroids ➢ Chorionic gonadotropin ➢ Estrogens and estrogen agonists ➢ Growth hormone ➢ Cyproterone ➢ Flutamide ➢ Isoniazid ➢ Ketoconazole ➢ Metronidazole ➢ Cimetidine, ranitidine ➢ Omeprazole ➢ Chemotherapeutic agents (especially alkylating agents) ➢ Amiodarone ➢ Captopril	➢ Reserpine ➢ Spironolactone ➢ Verapamil ➢ Psychoactive agents ➢ Diazepam ➢ Haloperidol ➢ Phenothiazines, ➢ Tricyclic antidepressants ➢ Alcohol ➢ Amphetamines ➢ Heroin ➢ Marijuana ➢ Highly active antiretroviral therapy ➢ Phenytoin ➢ Penicillamine	➢ Hepatic cirrhosis ➢ Uremia ***Endocrine*** ➢ Primary hypogonadism with Leydig cell damage ➢ Hyperprolactinemia ➢ Hyperthyroidism ➢ Androgen receptor disorders ➢ Excessive aromatase activity ***Idiopathic***

(hCG: Human chorionic gonadotropin)

Causes of Gynecomastia (Table 13.39)

Clinical features

- **Enlargement of breast:** The principal complaint is unilateral or bilateral concentric enlargement of breast glandular tissue.
- **Breast pain:** Present in one-fourth of patients and objective tenderness in about 40%.
- A complaint of nipple discharge can be elicited in 4% of cases.
- Patients with gynecomastia may have a slightly increased risk of development of breast carcinoma.

Treatment

- **Medical treatment:**
  - The **underlying disease** should **be corrected** if possible, and offending drugs should be discontinued.
  - **Antiestrogens or selective estrogen receptor modulators**, such as tamoxifen or raloxifene, have been found useful in relieving pain and reversing gynecomastia in some patients. Aromatase inhibitors have also been tried but are not as beneficial as tamoxifen.
- **Surgical treatment: Reduction mammoplasty** should be considered for cosmetic reasons.
- **Radiotherapy:**
  - Patients with **prostatic carcinoma** may receive low-dose radiation therapy (900c Gy or less) to the breasts before initiation of estrogen therapy. This may prevent or diminish the gynecomastia that usually results from such therapy.
  - Radiotherapy should not be given to other patients with gynecomastia.

Short Stature (Tables 13.40 and 13.41)

Q. PE2.4 Discuss the etiopathogenesis, clinical features and management of a child with short stature.

Q. Write a short note on short stature and its differential diagnosis.

- Short stature is defined as a height that is **below the 3rd percentile** OR **two or more standard deviations below** the mean for chronological age and gender for a given population.
- A **growth velocity that is below the 5th percentile** for age and gender is called **growth deceleration** (e.g., <5 cm/year after the age of 5 years).
- **Dwarfism** is defined as **short stature for the age** of the patient.
- Most common causes of dwarfism are **familial short stature** and **constitutional delay of growth and puberty.**

TABLE 13.40: Differential diagnosis of short stature.

Causes	*Characteristic findings*
GH deficiency	Frontal bossing, high-pitched voice, and central obesity
Hypothyroidism	Immature facies, dry skin, and coarse hair
Cushing's syndrome	Central obesity, striae, and hypertension
Gonadal dysgenesis	Webbed neck, multiple pigmented naevi, delayed sexual development, and shield chest
Pseudohypoparathyroidism	Moon facies, mental retardation, obesity, and short metacarpals
Bone-cartilage dysplasia	Abnormal proportions and macrocephaly
Russell-Silver dwarfism	Small at birth, pointed facies, and asymmetry
Other causes	Turner's syndrome, IUGR, premature birth, cyanotic congenital heart diseases, chronic liver disease, chronic pulmonary or kidney disease, undernutrition, uncontrolled type 1 diabetes mellitus, rickets, and malabsorption

(GH: growth hormone; IUGR: intrauterine growth retardation)

TABLE 13.41: Causes of short stature.

Nonendocrine causes	*Endocrine disorders*
➢ Constitutional short stature ➢ Familial short stature ➢ Genetic short stature ➢ Intrauterine growth retardation and SGA syndromes of short stature ➢ Turner's syndrome and its variants ➢ Noonan's syndrome (**Fig. 13.18A**) ➢ Prader–Willi syndrome ➢ Laurence–Moon and Bardet–Biedl syndromes ➢ Chronic disease ➢ Cardiac disorders (left-to-right shunt and congestive heart failure) ➢ Pulmonary disorders (cystic fibrosis and asthma) ➢ Gastrointestinal disorders: Malabsorption (e.g., celiac disease) ➢ Hematologic disorders ➢ Sickle-cell anemia ➢ Thalassemia ➢ Renal disorders ➢ Renal tubular acidosis ➢ Chronic uremia ➢ Immunologic disorders ➢ Connective tissue disease ➢ Juvenile rheumatoid arthritis ➢ Chronic infection (TB) ➢ Malnutrition ➢ Voluntary dieting ➢ Anorexia nervosa ➢ Cancer chemotherapy	➢ GH deficiency and variants ➢ Congenital GH deficiency – With midline defects – With other pituitary hormone deficiencies ➢ Isolated GH deficiency ➢ Pituitary agenesis ➢ Acquired GH deficiency ➢ Hypothalamic-pituitary tumors ➢ Histiocytosis X ➢ Central nervous systemic infections ➢ Head injuries ➢ GH deficiency following cranial irradiation ➢ Central nervous system vascular accidents ➢ Hydrocephalus ➢ Empty Sella syndrome ➢ Abnormalities of GH action ➢ GH insensitivity (Laron's dwarfism) ➢ Pygmies ➢ Psychosocial dwarfism ➢ Hypothyroidism ➢ Glucocorticoid excess (Cushing's syndrome) ➢ Pseudohypoparathyroidism ➢ Disorders of vitamin D metabolism ➢ Diabetes mellitus, uncontrolled ➢ Diabetes insipidus, untreated

Proportionate Short Stature

- Limbs proportionate to trunk
- Seen in most cases of familial short stature

Disproportionate Short Stature

- Limbs disproportionately short compared to trunk
- Seen mostly in cases of skeletal dysplasia

Growth failure: Growth rate below the rate considered appropriate for sex and age.

Tall Stature (Table 13.42)

Tall stature is defined as **height above 97th percentile** for chronological age and sex or **more than 2 SD** above the mean for a defined population.

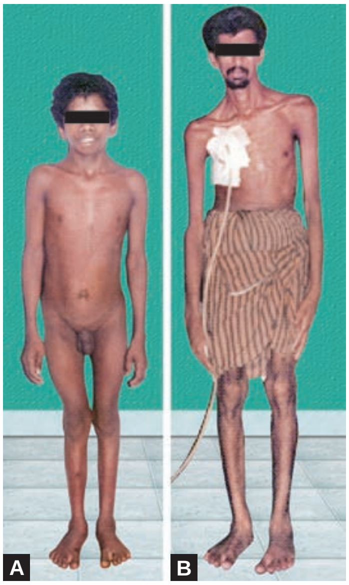
Q. How do we calculate height of child based on parental height?

Estimated adult height of a child calculated on the basis of parental height using the following formulas:

- ♂: [(Paternal height + Maternal height)/2] + 2.5” (6.5 cm)
- ♀: [(Paternal height + Maternal height)/2] – 2.5” (6.5 cm)

TABLE 13.42: Causes of tall stature.

Nonendocrine causes	*Endocrine disorders*
➢ Constitutional tall stature ➢ Genetic tall stature ➢ Cerebral gigantism ➢ Homocystinuria ➢ Marfan's syndrome (**Fig. 13.18B**) ➢ Beckwith–Wiedemann syndrome ➢ XYY and XYYY syndromes, Klinefelter's syndrome ➢ Syndromes of tall stature	➢ Pituitary gigantism ➢ Sexual precocity ➢ Thyrotoxicosis ➢ Infants of diabetic mothers



FIGS. 13.18A AND B: (A) Short stature in Noonan syndrome; (B) Tall stature in Marfan syndrome.

Oncology

CELL CYCLE

Q. Describe briefly about cell cycle and its regulation.

Cell replication proceeds through a number of phases that are biochemically initiated by external stimuli and modulated by both external and internal growth controls.

Phases of Cell Cycle (Table 14.1A and Fig. 14.1)

TABLE 14.1A: Phases of cell cycle.

G0 phase		**Gap 0 or resting phase or quiescent state**	Cells are generally programmed to perform specialized functions. Cells in this state remain quiescent for variable periods, but can be recruited in cell cycle if stimulator later
Interphase	***G1 phase***	**Gap 1 or presynthetic phase**	RNA synthesis occurs, and many of the enzymes necessary for DNA synthesis are manufactured
	S phase	**DNA synthetic phase**	The cellular content of DNA doubles
	G2 phase	**Gap 2 or postsynthetic phase or premitotic phase**	Protein and RNA syntheses continue, and the microtubular precursors of the mitotic spindle are produced
M phase		**Mitosis**	Genetic material is segregated into daughter cells with the help of microtubules: ➢ **Prophase:** The chromatin is condensing into chromosomes ➢ **Metaphase:** Chromosomes align at the metaphase plate ➢ **Anaphase:** Microtubules shorten resulting in chromosomal splitting ➢ **Telophase:** Decondensation of chromosomes with nuclear membrane formation

Regulators of Cell Cycle (Table 14.1B and Fig. 14.1)

TABLE 14.1B: Regulators of cell cycle.

Cyclins	➢ Synthesized during specific phases of cell cycle ➢ Appear sequentially in cell cycle in order D → E → A → B ➢ Their function is to activate CDKs
Cyclin-dependent kinases (CDK)	➢ CDKs are expressed constitutively during the cell cycle but in an inactive form ➢ They are activated by specific cyclins ➢ Their function depends on type of cyclin—CDK complex – **Cyclin D—CDK4, Cyclin D—CDK6, and Cyclin E—CDK2 complex** → phosphorylates RB, which is on-off switch of cell cycle. Phosphorylated RB activates E2F transcription factor, which is essential for transcription of genes needed for progression through S phase – **Cyclin A—CDK2 and Cyclin A—CDK1** → active in S phase – **Cyclin B—CDK1 complex** → essential for G2-M transition, it is the main mediator that propels the cell beyond prophase
CDK inhibitors	➢ They regulate the activity of Cyclin—Cdk complexes ➢ There are two classes of CDK inhibitors: 1. **Cip/Kip family:** They inactivate complexes formed between Cyclin and CDKs (e.g., p21, p27, p57, etc.) 2. **INK4/ARF family:** They block the cell cycle and act as tumor suppressors (e.g., p15, p16, p18, p19). p16/INK4a binds to cyclin D—CDK4 and promotes the inhibitory effects of RB; p14/ARF increases p53 levels by inhibiting MDM2 activity

Cell Cycle Checkpoints (Table 14.1C and Fig. 14.1)

TABLE 14.1C: Cell cycle checkpoints.

G1-S checkpoint	➢ It checks for DNA damage ➢ If DNA damage is present and repairable, DNA repair mechanisms are activated ➢ If DNA damage is present but not repairable, apoptotic pathways are activated ➢ It is controlled by p53 (by inducing p21)
G2-M checkpoint	➢ It monitors the completion of DNA replication and checks whether the cell can safely initiate mitosis ➢ It is controlled by both p53 dependent (via cyclin A—CDK2) and independent (via cdc 25) mechanisms ➢ Defect of G2-M checkpoint results in chromosomal abnormalities ➢ Cells damaged by ionizing radiation activate this checkpoint and arrest cells in G2 phase

Q. IM13.2 **Describe the genetic basis of selected cancers.**

Q. **Write short essay/note on:**

- **Proto-oncogene, oncogene, and tumor suppressor gene.**

Regulation of Cancer Cell Growth

Normal cell may undergo malignant transformation by corrupting any one of the normal steps involved in cell proliferation. Abnormal regulation of cell growth in cancer can occur as the result of several mechanisms. All cancers show eight fundamental changes in cell physiology. These are considered the hallmarks of cancer and include:

- **Self-sufficiency in growth signals (activation of cell growth):** Cancers use multiple mechanisms to sustain their proliferation:
  - Tumors may produce growth factors for which they have receptors in an autocrine fashion.
  - Tumors may stimulate surrounding normal tissues and these normal tissues provide growth factors for the tumor.
  - Tumor may become hypersensitive to growth factors through upregulation of growth receptors or alterations of the structure of these receptors.
  - Finally, they may become independent of growth factors by the presence of somatic mutations activating downstream pathways [e.g., BRAF mutations activating the mitogen-activated protein kinase (MAPK) pathway, or mutations in phosphoinositide-3-kinase (PI3K) leading to activation of the PI3K/Akt/mTOR pathway, or by altering the negative feedback loops].

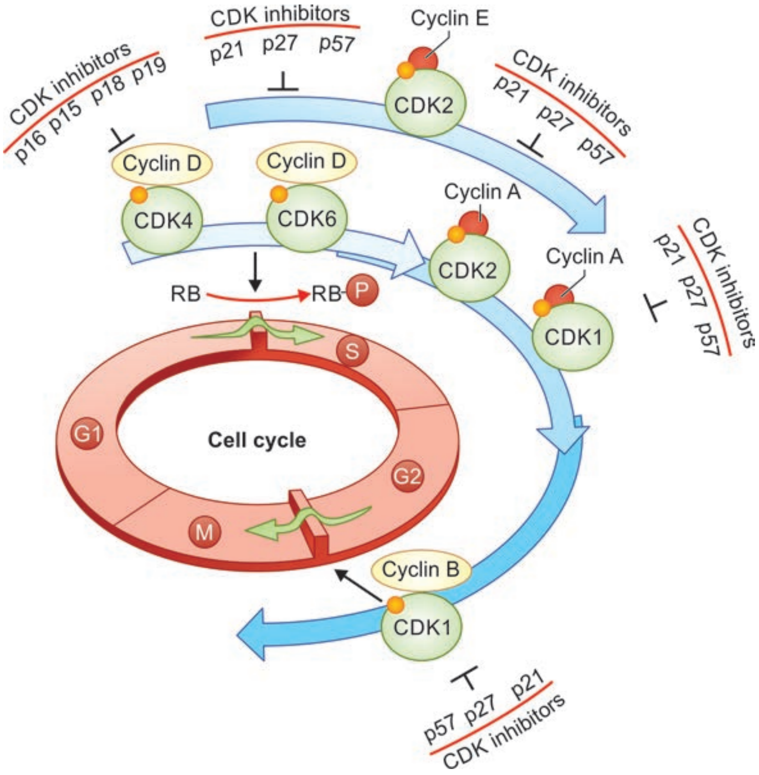

FIG. 14.1: Pictorial representation of cell cycle, cyclin-CDK complexes, CDK inhibitors, and cell cycle checkpoint.
(CDK: Cyclin-dependent kinase)

Proto-oncogenes, Oncogenes

Proto-oncogenes are normal cellular genes, which encode a number of nuclear proteins that **regulate normal cell proliferation, differentiation, and survival**. Genes that promote **autonomous cell growth** in cancer cells are called ***oncogenes*** and are altered/mutated versions of proto-oncogenes.

Oncogenes and oncoproteins: Oncogenes can promote cell growth in the absence of normal growth-promoting/mitogenic signals. Oncoproteins are products of oncogenes and resemble the normal products of proto-oncogenes. Oncoproteins production is not under normal regulatory control. Cells proliferate without the usual requirement for external signals and are freed from checkpoints and **growth becomes autonomous**. Oncogenes are classified depending on the function of gene product (oncoprotein) **(Table 14.2)**.

Tumor Suppressor Genes

- **Insensitivity to growth-inhibitory signals (inhibition of tumor suppressor genes):** Second mechanism of carcinogenesis results from failure of growth inhibition, due to **deficiency of normal tumor suppressor genes** and **their products**. **Tumor suppressor genes (Table 14.4)** apply brakes to cell proliferation and prevent uncontrolled/abnormal cell proliferation and induce repair or self-death (apoptosis). Important tumor suppressor genes are *RB*, *p53*, *BRCA1*, and *BRCA2* genes.
    - The **RB** protein is responsible for the control of the cell cycle and the switch from resting state to cell division, mainly in response to the stimuli outside of the cell. The cells that lack the RB protein do not have this control mechanism.
    - The **p53** protein is also a cell cycle control protein, but it responds mainly to the intracellular stressors, and it can stop cell cycle until the abnormal processes have been corrected. the p53 protein arrests cells in the quiescent G1 and G2 phases of the cell cycle, preventing cells from entering the DNA synthetic (S) phase of the cell cycle. It can detect DNA abnormalities, such as nucleotide mismatches and DNA strand breaks, including those caused by radiation and chemotherapy. The function of p53 is thought to be critical in preserving the integrity of the cellular genome.
    - The ***NF2*** gene and its product **Merlin**. Merlin is responsible for maintaining of contact inhibition through E-cadherins. Normal cells stop proliferating when a desired density of cells is achieved. This process is dysregulated in cancer (loss of contact inhibition).
    - The **LKB1** epithelial polarity protein is responsible for maintaining tissue integrity and contributes to the contact inhibition phenomenon. The functional LKB1 can even overcome signals originating from strong oncogenes such as *Myc*.
    - Tumor growth factor-β (TGF-β) functions as a suppressor of tumor growth, but in the advanced malignancies its function may change and it may lead to increased aggressiveness of cancer through promotion of the epithelial-to-mesenchymal transformation.
    - Structural abnormalities associated with oncogenes are presented in **Table 14.3** and few examples of tumor suppressor genes and tumors in which they are affected are listed in **Table 14.4**.
- **Growth-promoting metabolic alterations:** Cancer cells show a distinctive form of cellular metabolic alteration (even in the presence of adequate oxygen) characterized by high levels of glucose uptake (via upregulation of GLUT 1 receptors) and increased conversion of glucose to lactose (fermentation) via the glycolytic pathway. This is known as the **Warburg effect** or aerobic glycolysis. Glycolytic intermediate processes are used by cancer cells for generation of nucleosides and amino acids that are essential for tumor proliferation and growth.

TABLE 14.2: Classification of oncogenes.

Classification of oncogenes	*Example/s of associated tumor/s*
Growth factors	
PDGF **(platelet-derived growth factor)**	Nonsmall cell cancer of lung
TGF-α (tumor growth factor-alpha)	Hepatocellular cancer
Growth factor receptors	
EGFR **(epidermal growth factor receptor)**	Lung and gastrointestinal tumors
Her 2/neu receptor	Breast cancer
KRAS	Adenocarcinoma of colon, lung, and pancreas
NRAS	Hematopoietic tumors, melanomas
ABL	Chronic myeloid leukemia, acute lymphoblastic leukemia
Nuclear-regulatory proteins/transcription factors	
C-MYC	Burkitt's lymphoma
N-MYC	Neuroblastoma
Cell cycle regulators	
Cyclin D	Breast, esophageal, and liver cancers

TABLE 14.3: Structural abnormalities associated with oncogenes.

Oncogene	*Aberration*	*Neoplasm*
abl	t(9;22)	CML, AML, ALL
myc	t(8;14)	Burkitt's lymphoma, B-ALL, T-ALL
bcl-1, bcl-2	t(11;14)	B-cell lymphoma

(CML: Chronic myeloid leukemia; AML: Acute myeloid leukemia; ALL: Acute lymphoid leukemia; APML: Acute promyelocytic leukemia)

TABLE 14.4: Few examples of tumor suppressor genes and tumors in which it is affected.

		Tumors in which gene is affected	
Gene (locus)	*Function*	*Familial*	*Sporadic*
DCC (18q)	Cell surface interaction	Not known	Colorectal cancer
Rb1 (13q)	Transcription	Retinoblastoma	Small cell carcinoma of lung
p53 (17p)	Transcription	Li-Fraumeni syndrome	Cancer of breast, colon, and lung
BRCA1(17q)	Transcription	Carcinoma breast	Carcinoma breast/ ovary
BRCA2 (13q)	Regulator/ DNA repair		
WT1 (11p)	Transcription	Wilms' tumor	Lung cancer

- **Evasion of cell death (Apoptosis, Autophagy, and Necrosis):** ***Apoptosis*** is a programmed cell death and is one of the normal protective mechanism by which a cell with DNA damage (mutation) undergoes cell death. Mutations in the genes that regulate apoptosis may lead to neoplasm. **Examples (Table 14.5)**.

  Autophagy is a natural process that allows cells to break down intracellular organelles upon exposure to stressors with help of lysosomes and recycle nutrients. It is also a protective process in case of neoplastic transformation. Cancer cells may use autophagy to recycle their nutrients and escape damaging agents. This process is regulated by PI3-kinase, AKT, and mTOR pathway and by protein Beclin-1.

  Necrosis is another process of cell death in which cells increase in size and break, releasing multiple proinflammatory cytokines. Immune cells are attracted to the areas of necrosis to eliminate the remnants of cells. Cancer can use this process to induce an inflammatory paraneoplastic environment, stimulate angiogenesis, and even use these cytokines to stimulate its own growth.

TABLE 14.5: Genes regulating apoptosis.

Proapoptotic genes	***Antiapoptotic genes***
Examples: Bax, bak, bok, bik, bad, bod, bid, Bcl-xS, PUMA, Noxa	***Examples:*** Bcl-2 family (Bcl-2, Bcl-xL, Bcl-w, Mcl-1, A1)
Inhibition of proapoptotic genes predisposes to cancer	Upregulation of antiapoptotic genes predisposes to cancer

- **Limitless replicative potential:** All malignant tumors contain cells that are immortal and have limitless replicative potential.
  - *Cancer stem cells:* At least few cells in all cancers have stem cell-like properties and are called cancer stem cells.
  - *Reactivation of telomerase:* During the course of repeated cell cycles, there is progressive shortening of telomeres, making the cells vulnerable to senescence/apoptosis. The cells that are able to maintain the activity of telomerase, an enzyme that is responsible for lengthening of telomeres, can potentially proliferate uncontrollably and turn into cancer.
- **Development of sustained angiogenesis:** Microscopic lesions rely on osmosis for delivery of nutrients, but it has been shown that early in carcinogenesis, the "angiogenic switch" occurs that promotes new blood vessel formation. Vascular endothelial growth factor A (VEGF-A) is the main protein responsible for neoangiogenesis. Its action is counterbalanced by the activity of thrombospondin-1 (TSP-1).
- **Ability to invade and metastasize (invasion and metastasis):** Cancer cells are characterized by a unique ability of local invasion and formation of distant metastasis. E-cadherin is one of most important cell surface adhesion molecules responsible for maintaining tissue integrity. Multiple cancers express E-cadherin at a low level and express molecules implicated in cell migration such as N-cadherin at higher levels. Formation of distant metastasis is a multistep process and it consists of the following:
  - Local invasion
  - Migration into lymphatic and blood vessels
  - Spread of cancer cells through vasculature
  - Extravasation of cancer cells into tissue of remote organs
  - Growth of cancer cells in the new environment to form macroscopic tumors

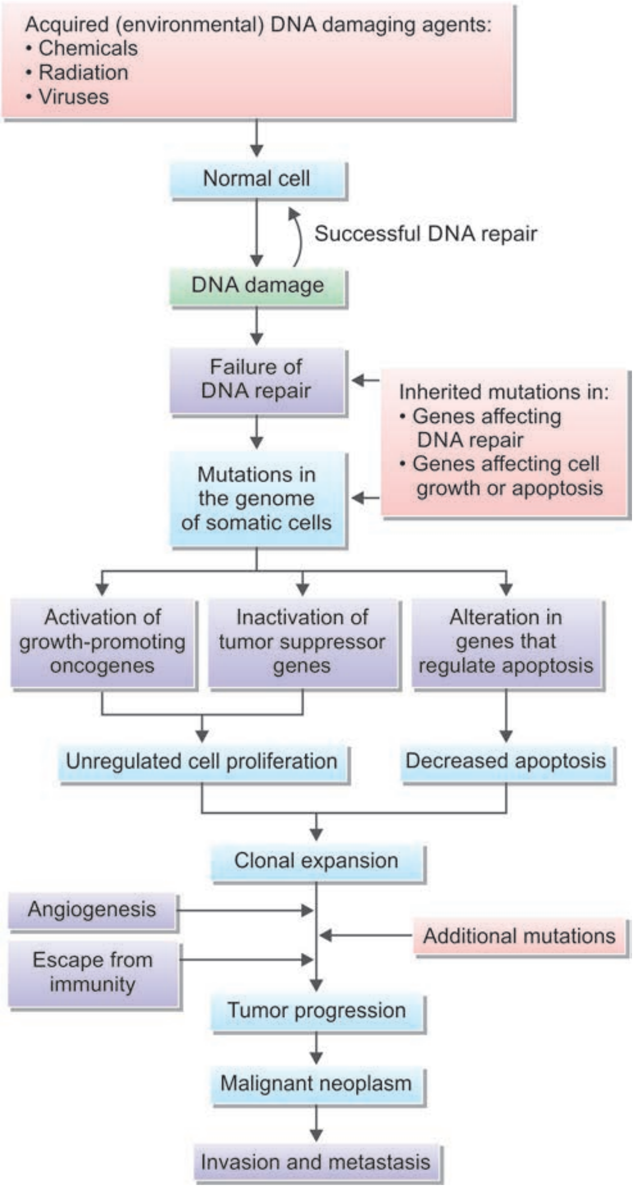
  Molecular events occurring during the process of formation metastasis resemble steps of embryonic morphogenesis. The process by itself has been named **epithelial–mesenchymal transition (EMT)** and involves genes playing a physiologic role in embryogenesis such as Snail, Slug, Twist, and Zeb1/2. These genes are regulated by the intracellular oncogenic events, but they can be also influenced by microenvironmental stimuli.
- **Ability to evade the host immune response:** The immune cells eliminate pathogens and potentially cancerous cells. Cancer cells evade this surveillance by disabling components of the immune system.

GENETIC BASIS OF TRANSFORMATION OF A NORMAL CELL INTO A MALIGNANT CELL

Molecular Basis of Cancer

- Nonlethal genetic damage lies at the heart of carcinogenesis. Such genetic damage (or mutation) may be acquired by the action of environmental agents, such as chemicals, radiation, or viruses, or it may be inherited in the germ line **(Flowchart 14.1)**.
- A tumor is formed by the clonal expansion of a single precursor cell that has incurred genetic damage.
- Four classes of normal regulatory genes—the growth-promoting proto-oncogenes, the growth-inhibiting tumor suppressor genes, genes that regulate programmed cell death (apoptosis), and genes involved in DNA repair—are the principal targets of genetic damage.
- Carcinogenesis is a multistep process at both the phenotypic and the genetic levels, resulting from the accumulation of multiple mutations.

FLOWCHART 14.1: Flowchart depicting simplified scheme of molecular basis of cancer.



Acquired (environmental) DNA damaging agents:
• Chemicals
• Radiation
• Viruses
Normal cell
Successful DNA repair
DNA damage
Failure of DNA repair
Inherited mutations in:
• Genes affecting DNA repair
• Genes affecting cell growth or apoptosis
Mutations in the genome of somatic cells
Activation of growth-promoting oncogenes
Inactivation of tumor suppressor genes
Alteration in genes that regulate apoptosis
Unregulated cell proliferation
Decreased apoptosis
Clonal expansion
Angiogenesis
Escape from immunity
Additional mutations
Tumor progression
Malignant neoplasm
Invasion and metastasis

Kinetics of tumor growth: Tumor growth depends on the size of the proliferating pool of cells and the number of cells dying spontaneously. The larger the tumor mass, the greater the percentage of nondividing and dying cells and the longer it takes for the average cell to divide.

a. The lag phase	➢ During the earliest phase of tumor development, a small mass of a tumor does not enlarge very much. ➢ During this phase, the dividing cells are accumulating various mutations. These mutations help the surviving cells improve their adaptivity to the supply of nutrients, increase the rate at which the mutated cells divide, decrease the rate of apoptosis sensitivity, provide them with invasive properties, make the mutated cells more responsiveness to host factors, and produce angiogenesis factors.
b. The log phase	➢ The tumor now shows rapid exponential growth of the tumor mass. ➢ There is a relatively high proportion of cells undergoing division, with rapidly declining rates of cell death, and the *growth fraction* (ratio of dividing to total cells) is high. ➢ This rapid growth also reflects the adaptivity of the cells and the production by the tumor cells of angiogenesis factors that induce the surrounding tissues to form new blood vessels that "feed" the tumor mass.
c. The plateau phase	➢ Tumor growth slows down as the percentage of dividing cells decreases, and a larger percentage of cells are dying. ➢ The hypotheses are that growth rates eventually plateau because of restrictions of space and nutrient availability, of limitation of blood supply, and of genetic mutations, which cause a higher death rate of cells.

Genomic Stability

The mechanisms responsible for genome stability (repair mechanisms) assure that any randomly created mutations are repaired or an abnormal cell is eliminated. In the presence of external mutagens or heritable susceptibility factors such as mutations in tumor suppressor genes, the repair mechanisms malfunction and allow abnormal cells to survive. The genes involved are caretaker genes and gatekeeper genes as described below:

Caretaker genes	They are responsible for: ➢ Detecting DNA damage and activating the repair mechanisms ➢ Repairing damaged DNA directly ➢ Inactivating mutagenic factors	Inactivation of caretaker genes leads to an increased mutation rate and increased genome instability
Gatekeeper genes	They are responsible for inhibiting tumor growth or promoting death	A mutation in such a gene may promote the development of cancer by decreasing the DNA repair window from G1 to S phase

Tumor-promoting Inflammation

Tumors consist not only of neoplastic cells but also of a variety of cells of the innate and adaptive immune systems. The density of immune cells and their localization within the tumor are different among different malignancies. Initially it was postulated that the presence of these cells reflected an attempt of eradication of a tumor by the immune system. Currently we know that these inflammatory infiltrates can actually promote tumorigenesis and cancer growth by providing cytokines and growth and survival factors for the tumor, by stimulating angiogenesis, and by facilitating invasion and metastasis. Inflammation can ignite the transition from a premalignant state to full malignancy (e.g., by release of reactive oxygen species that have mutagenic capabilities).

Q. What are the differences between benign and malignant tumors (Table 14.6)?

TABLE 14.6: Differences between benign and malignant tumors.

Characteristic	***Benign tumors***	***Malignant tumors***
Surface	Usually regular with surrounding capsule	Usually irregular without a surrounding capsule
Differentiation/anaplasia	Well differentiated; may resemble tissue of origin	Varies from well differentiated to poorly differentiated; structure often atypical
Rate of growth	Usually progressive and slow	Erratic and may be slow to rapid
Mitotic figures	Rare and normal	Common and abnormal
Local invasion	Usually well-demarcated masses that do not invade or infiltrate surrounding normal tissues	Locally invasive, infiltrating surrounding tissue
Metastasis	Absent	Frequently present (almost all cancers metastasize except gliomas and basal cell carcinoma)

Q. Write a short note on metaplasia, dysplasia, and anaplasia (Table 14.7).

TABLE 14.7: Characteristics of metaplasia, dysplasia, and anaplasia.

Characteristic	***Metaplasia***	***Dysplasia***	***Anaplasia***
Definition	Reversible change in which one differentiated cell type is replaced by another cell type	A loss in uniformity of the individual cells and loss of architectural orientation	An absence of differentiation
Pleomorphism	Absent	Present in low grade	Present in high grade
Reversibility	Reversible	Reversible in early stages	Irreversible
N:C ratio	Normal	Mildly increased	Grossly increased
Hyperchromatism	Absent	Present in small degree	Present in high degree
Mitotic figures	Absent	Typical mitotic figures present at abnormal places	Atypical mitotic figures at abnormal places
Examples	Barrett's esophagus	Cervical dysplasia	Carcinoma cervix

Common Cancers

Q. IM13.1 Describe the clinical epidemiology and inherited and modifiable risk factors for common malignancies in India (Tables 14.8 and 14.9).

TABLE 14.8: Prevalence of cancer—World and India.

Prevalence of cancer	***World***	***India***
Most common cancer (men)	Carcinoma lung	Lip and oral cavity cancer
Most common cancer (women)	Breast cancer	Breast cancer
Most common cancer (overall—men and women)	Carcinoma lung	Breast cancer
Most common cause of cancer deaths (overall—men and women)	Carcinoma lung	Breast cancer

Source: GLOBOCAN 2020 (for updated statistics please refer GLOBOCAN fact sheet).

Risk Factors of Cancer

TABLE 14.9: Risk factors for cancer.

Intrinsic risk factors	***Nonintrinsic risk factors***	
Nonmodifiable risk factor	**Endogenous risk factors (Partially modifiable risk factors)**	**Exogenous risk factors (Modifiable risk factors)**
Refers to unavoidable spontaneous mutations that arise as a result of random errors in DNA replication	Aging Genetic susceptibility Hormones Growth factors Chronic inflammation, etc.	Exposure to radiation Exposure to carcinogens Infections Smoking Obesity Dietary imbalance Physical inactivity, etc.

Etiology of Cancer

Q. Write a note on etiological factors of cancer—genetic, chemical, infectious agents.

Genetic Predisposition (Table 14.10)

TABLE 14.10: Genetic predisposition to cancer.

Gene involved	*Syndrome associated*
Autosomal dominant cancer syndromes (mnemonic: **V**ery **R**ich, **C**ute, **N**ice **M**en **H**ereditarily **L**ike/**P**refer **F**amiliar **Women**)*

Promotion
Preneoplastic clone
Proliferation
Additional mutations
Malignant neoplasm

Chemical Carcinogenesis (Flowchart 14.2 and Table 14.11)

- It is a two-step process.
    1. **Initiation:** Initiation results from exposure of cells to a sufficient dose of a carcinogenic agent (initiator). Initiation alone, however, is not sufficient for tumor formation. Initiation causes permanent DNA damage (mutations). It is therefore rapid and irreversible and has "memory". It can be two types of agents (directly acting and indirectly acting agents).

Direct-acting agents	*Indirect-acting agents*
Direct-acting agents require no metabolic conversion to become carcinogenic. Most of them are weak carcinogens	The designation *indirect-acting agent* refers to chemicals that require metabolic conversion to an *ultimate carcinogen* before they become active *For example:* Benzopyrene and other carcinogens are formed in the high-temperature combustion of tobacco in cigarette smoking

    2. **Promotion:** Promoters can induce tumors in initiated cells, but they are nontumorigenic by themselves. The cellular changes resulting from the application of promoters do not affect DNA directly and are reversible. Promoters enhance

TABLE 14.11: List of carcinogenic agents and the cancer associated.

Agent	*Cancer associated*
Arsenic and arsenic compounds	Lung, skin, hemangiosarcoma
Asbestos	Lung, mesothelioma; gastrointestinal tract (esophagus, stomach, large intestine)
Aromatic amines	Bladder cancer
Alkylating agents	AML, bladder cancer
Benzene	Acute myelocytic leukemia, Hodgkin's lymphoma
Beryllium compounds	Lung cancer
Chromium	Lung cancer
Cadmium	Prostate cancer
Estrogens	Breast, endometrium, liver cancers
Ethyl alcohol	Liver cancer, esophagus, and head and neck cancers
Immunosuppressive agents	Non-Hodgkin's lymphoma (NHL)
Nickel compounds	Lung cancer
Phenacetin	Renal pelvis and bladder cancer
Tobacco	Upper aerodigestive tract, bladder cancers

the proliferation of initiated cells, an effect that may contribute to the development of additional mutations in these cells.

Q. Write a short note on Ames test. Test for mutagenicity (Ames test) (Fig. 14.2).

It is a biological assay to assess the mutagenic potential of chemical compounds. A positive test indicates that the chemical is mutagenic and therefore may act as a carcinogen. The Ames test uses several strains of the bacterium *Salmonella typhimurium* that carry mutations in genes involved in histidine synthesis. These strains are auxotrophic mutants (i.e., they require histidine for growth, but cannot produce it). The method tests the capability of the tested substance in creating mutations that result in a return to a "prototrophic" state, so that the cells can grow on a histidine-free medium.

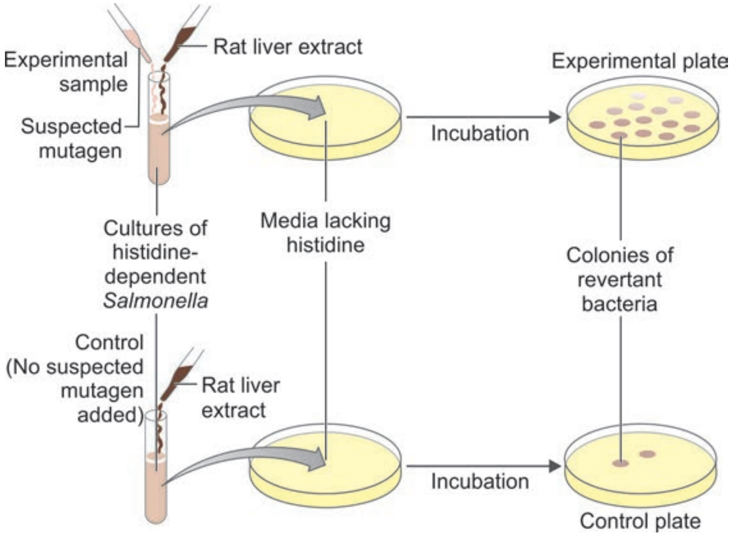

FIG. 14.2: Ames test—test for mutagenicity.

Infection and Cancer (Table 14.12)

Q. IM13.3 Describe the relationship between infection and cancers.

Q. Describe the role of oncogenic viruses in the evolution of virus-associated malignancy.

TABLE 14.12: Infections associated with malignancy.

Organism	***Malignancy associated***	***Additional points***
Bacterial infections		
Helicobacter pylori	Gastric adenocarcinoma Gastric lymphomas [B-cell origin—MALT lymphomas t(11;18)]	
Viral infections		
Oncogenic RNA viruses		
Human T-cell lymphotropic virus type 1	Adult T-cell leukemia/lymphoma	The product of TAX gene in HTLV-1 is responsible for transcription of host genes involved in proliferation and genomic instability by inhibiting DNA repair function
Oncogenic DNA viruses		
1. **Human Papillomavirus**		
– HPV types 1, 2, 4, and 7	Benign squamous papilloma (wart)	Low-oncogenic risk HPV—benign lesions of squamous epithelium
– HPV-6 and HPV-11	Condylomata acuminata (genital warts) of the vulva, penis, and perianal region	
– HPV types 16 and 18	Squamous cell carcinoma of the cervix and anogenital region Oropharyngeal cancers	High-oncogenic risk HPV—malignant tumors (E6 and E7 genes are responsible for inactivation of tumor suppression genes p53 and Rb genes, respectively)
2. **Epstein-Barr virus**	Burkitt's lymphoma Hodgkin's lymphoma Nasopharyngeal cancer	t(8;14) is responsible for Burkitt's lymphoma. Genes implicated are LMP-1 gene, EBNA-2, and vIL-10
3. **Hepatitis B and C viruses**	Hepatocellular carcinoma	HBx gene (Hepatitis B) is responsible for the activation of growth promoting genes and inactivation of p53 gene
4. **Human Herpesvirus-8**	Kaposi's sarcoma Pleural effusion lymphoma, multicentric Castleman's disease	
5. **Merkel Cell Polyoma Virus**	Merkel cell carcinoma	
Parasitic infections		
1. **Blood flukes *(Schistosoma haematobium)***	Bladder cancer	
2. **Liver flukes (*Clonorchis sinensis* and *Opisthorchis viverrini*)**	Cholangiocarcinoma	
3. ***Plasmodium falciparum***	Burkitt's lymphoma	Coexisting with EBV
Fungal infections/toxins		
1. ***Aspergillus sps.***	Esophageal cancer, hepatocellular cancer	Aflatoxins are responsible for oncogenesis

CANCER SCREENING AND PREVENTION

Q. Write a note on cancer screening and prevention (Tables 14.13 and 14.14).

Q. IM13.15 Describe the need, tests involved, and their utility in the prevention of common malignancies.

Investigations

TABLE 14.13: Screening tests for cancers.

Breast cancer	Breast self-examination Clinical examination Mammography MRI (especially in young and with germline mutations in the family) Tomosynthesis
Cervical cancer	Pap smear HPV testing
Colorectal cancer	Sigmoidoscopy Fecal occult blood testing Colonoscopy Fecal DNA testing Fecal immunochemical testing CT colonography
Lung cancer	Low-dose computed tomography (LDCT)
Ovarian cancer	CA-125 Transvaginal ultrasound
Prostate cancer	Prostate-specific antigen (PSA) Digital rectal examination (DRE)

TABLE 14.14: Cancer prevention.

Cancer vaccines (preventive)	**Hepatitis B vaccine**	Recombinant vaccine used for prevention of hepatitis B-induced HCC (total of three doses administered over 6 months—at 0, 1, and 6 months)
	HPV vaccine	Protect against acquisition of HPV infection and development of subsequent HPV-associated disease (oropharyngeal cancer, cervical cancer, vaginal cancer, vulvar cancer, and anal cancers) ***Quadrivalent HPV vaccine (Gardasil) targets*** HPV types 6, 11, 16, and 18 ***9-valent vaccine (Gardasil 9)*** targets the same HPV types as the quadrivalent vaccine (6, 11, 16, and 18) as well as types 31, 33, 45, 52, and 58 ***Bivalent vaccine (Cervarix)*** targets HPV types 16 and 18 Ideal age of immunization is before first sexual exposure **Before 15 years of age:** Two doses of HPV vaccine should be given at 0 and at 6–12 months **15 years of age or older:** Three doses of HPV vaccine should be given at 0, 2, and 6 months **Immunocompromised patients:** Three doses of HPV vaccine should be given at 0, 1–2, and 6 months regardless of age  Start taking early ages 9–10 2 doses On time ages 11–12 2 doses ✓ Late ages 13–14 2 doses Late ages 15–16 3 doses Early On time Late Late
Chemo-preventive drugs	**Breast cancer**	Tamoxifen, raloxifene, and estramustine
	Colorectal cancer	Nonsteroidal anti-inflammatory drugs (NSAIDs), such as piroxicam, sulindac, and aspirin, may prevent adenoma formation or cause regression of adenomatous polyps
	Prostate cancer	Finasteride and dutasteride are 5 α-reductase inhibitors. They inhibit conversion of testosterone to dihydrotestosterone (DHT), a potent stimulator of prostate cell proliferation
Surgical prevention of cancer	**Cervical cancer**	Women with severe cervical dysplasia are treated with laser or loop electrosurgical excision or conization and occasionally even hysterectomy
	Colorectal cancer	Colectomy is used to prevent colon cancer in patients with familial polyposis or ulcerative colitis
	Breast and ovary cancer	Prophylactic bilateral mastectomy and prophylactic salpingo-oophorectomy in high-risk individuals especially BRCA1 and BRCA2 mutations

DIAGNOSIS AND STAGING OF CANCER

Q. 13.11, 13.12 **Enumerate the list of investigations useful in diagnosis, staging, and monitoring response to treatment in a cancer patient (Table 14.15).**

Q. Order and interpret diagnostic testing based on the clinical diagnosis including CBC and stool occult blood, and prostate-specific antigen.

TABLE 14.15: Investigations and evaluation in cancer patient.

Complete blood picture and peripheral smear	➢ Low hemoglobin is commonly encountered with chronic diseases like cancer ➢ High leukocyte and abnormal differential count should rise suspicion of leukemias ➢ Abnormal cells or blast in peripheral smear should be characterized and evaluated with bone marrow aspiration and biopsy ➢ Cytopenias are usually seen in patients who are on cytotoxic chemotherapies
Renal failure **Hypercalcemia** **Anemia**	➢ Usually seen in multiple myeloma
Liver function test (LFT)	➢ Conjugated bilirubin is elevated in biliary tract obstruction secondary to cancer around hepatobiliary system and periampullary carcinoma of pancreas ➢ Gamma-glutamyltransferase (GGT) elevated in hepatocellular carcinoma (HCC)
Stool occult blood	➢ Positive stool occult blood suggests gastrointestinal (GI) bleeding and needs to be evaluated for source of bleeding
Urine routine	➢ Hematuria and abnormal cells in the urine may suggest pathology of genitourinary tract
Renal failure **Hypocalcemia** **Hyperkalemia** **Hyperphosphatemia**	➢ Seen in tumor lysis syndrome
Apart from regular investigations, the following investigations are cardinal in the diagnosis and management of cancer patients	
Tumor markers (Table 14.16)	➢ Tumor markers are biochemical substance/product of malignant tumors that can be detected in the cells themselves or in serum/blood and/or body fluids ➢ Tumor markers can be a normal endogenous products produced in excess by cancer cells or products of newly switched on genes that remained quiescent in the normal cells ➢ Concentration increases with tumor progression, highest levels when tumors metastasize ➢ Include diverse molecules, such as serum proteins, oncofetal antigens, hormones, metabolites, receptors, and enzymes ➢ Tumor markers may be useful in management in certain cancers. In a particular patient, rising and falling levels of the tumor marker are usually associated with increasing or decreasing tumor burden, respectively ➢ Tumor markers help in: – Screening populations at risk – Diagnosis – Prognosis – Detection of recurrence – Monitoring response to treatment – Immunodetection of metastatic sites ***Disadvantage:*** Tumor markers are not in themselves completely specific enough for the diagnosis of malignancy. They may also be raised in few benign lesions. Few markers are specific for a single individual tumor. Most are found with different tumors of the same tissue type. They are present in higher quantities in blood from cancer patients than in blood from both healthy subjects and patients with benign diseases. However, once a malignancy has been diagnosed and shows elevated levels of a tumor marker, the marker can be used to assess response to treatment
Immunohistochemistry (IHC)	➢ IHC takes its name from the word "immuno", referring antibodies used in the procedure, and "histo", meaning tissue ➢ It involves the process of selectively identifying antigens in cells of a tissue section (specimen) with the help of specific antibodies binding against them ➢ It helps in identifying tissue of origin as well as guiding the treatment (for targeted therapy) ➢ Example: CD3 on T cells, CD117+ suggest gastrointestinal stromal tumor (GIST), Vimentin+ suggest sarcomas
Comparative genomic hybridization (CGH)	➢ It detects the amplifications and deletions of small DNA regions throughout the whole genome ➢ The tested DNA is compared to the normal one to identify the areas of DNA gains and losses. Single nucleotide polymorphism (SNP) array is a form of targeted CGH that can help with detection of either absence or loss of heterozygosity ***Disadvantage:*** This method is not able to detect balanced translocations, inversions, or insertions, as these changed do not have change in copy number
Fluorescence in situ hybridization (FISH)	➢ **Fluorescence in situ hybridization** used to detect large chromosome abnormalities; however, it can detect smaller microdeletions or duplications ➢ The fluorescent labeled probes hybridize with a DNA sequence of interest and appear under the microscope as a fluorescent dot ➢ When normal chromosomes are present, two dots should be seen for each pair of chromosomes ➢ If only one is seen, it is equal to a chromosome loss; if more than two are present, it shows additional chromosomes ➢ FISH can also be used to detect translocations. Probes of two different colors are used: one for each gene of interest. Normally they should be on two different chromosomes. If translocation is present, these dots will overlap.

Contd...

Contd...

Apart from regular investigations, the following investigations are cardinal in the diagnosis and management of cancer patients	
Next-generation sequencing (NGS)	➢ In NGS, multiple small fragments of DNA are sequenced in parallel; first the patient's purified DNA is amplified and then fragmented. The data are analyzed by computers and aligned against reference DNA; thus, the whole sequence is restored from fragments ➢ ***Third-generation sequencing*** uses the same concept, but with a single DNA molecule as a template in attempt to reduce the frequency of errors caused by amplification ➢ NGS can be applied to the whole genome (coding and noncoding DNA), exons (only coding DNA, as 85% of mutations occur in these regions), or even small regions of DNA (targeted areas genes) ➢ ***Targeted sequencing*** is faster, is less expensive, and decreases the chance for identification of VUS (variant of uncertained significance) ➢ The clinical applicability of the results of sequencing must be approached with caution: a significant number of nonpathogenic genes are identified and they must be skillfully differentiated from pathogenic genes ***Disadvantages:*** ➢ The results are compared to the results available in mutation databases, but currently available databases are not comprehensive enough ➢ Ordering of these tests is not always appropriate, especially when the results are unlikely to change the diagnosis or treatment
Gene expression profiling	**Gene expression profiling is the measurement of the activity of thousands of genes at once,** to obtain overall picture of cellular function. These profiles can (e.g. distinguish between cells that are actively dividing, or show how the cells react to a particular treatment). Example: **Microarrays (oligonucleotide arrays)** and **gene expressions test** (RS—Oncotype Dx) in patients with breast cancer may identify patients who are most and least likely to derive benefit from adjuvant chemotherapy
Liquid biopsy	A **liquid biopsy**, also known as **fluid biopsy** or **fluid phase biopsy**, is the sampling and analysis of nonsolid biological tissue, primarily blood. It is mainly used as a diagnostic and monitoring tool for diseases such as cancer, with the added benefit of being largely non noninvasive
MIBG scan	**Metaiodobenzylguanidine (MIBG)** imaging of norepinephrine transporter ➢ **Indication:** To identify metastatic and primary tumor sites for pheochromocytoma/paraganglioma, and neuroblastoma ➢ **Radiopharmaceutical:** Iobenguane sulfate, 131I-MIBG sulfate, or 123I-MIBG sulfate ➢ **Principle:** MIBG is normally concentrated by adrenergic tissues in cytoplasmic storage granules that also contain other catecholamines
Pentetreotide (octreotide) imaging	**Pentetreotide (octreotide) imaging** ➢ **Indication:** For diagnostic workup of neuroendocrine tumors that bear somatostatin receptors ➢ **Radiopharmaceutical:** Pentetreotide is a diethylenetriaminepentaacetic acid (DTPA) chelate conjugate of octreotide, which is a long-acting analog of human somatostatin. 111In is bound to the chelate ➢ **Principle:** 111In-pentetreotide binds to somatostatin receptors (SSTRs), particularly SSTR subtype 2, throughout the body. Neuroendocrine tumors highly express these receptors and thus concentrate sufficient amounts of the radioactive agent to be seen by scintigraphy
PET scan (Figs. 14.3A and B)	➢ Positron emission tomography (PET) detects metabolic activity of tumor cells following injection of small amounts of radioactive tracers, such as fluorodeoxyglucose (FDG)  **FIGS. 14.3A AND B:** PET images of a case of non-Hodgkin's lymphoma. (A) Before chemotherapy; (B) After two cycles of doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD). ➢ **Uses:** – It is used for screening for (1) preliminary diagnosis, (2) accurately assess the severity and spread of cancer, (3) biopsy guidance, (4) staging, (5) prognostication, (6) therapeutic planning, and (7) judging response to therapy – PET has been found to be useful in several malignancies including melanoma, lymphoma, lung cancer, esophageal cancer, head and neck cancer, breast cancer, and thyroid cancer – Useful in diagnosing certain cardiovascular and neurological diseases because it highlights areas with increased, diminished or no metabolic activity – Also positive in patients with granulomatous diseases, like tuberculosis and sarcoidosis ➢ **Method:** – FDG is injected intravenously and is transported from the plasma to the cells by glucose transporters (GLUT 1 and GLUT 4) – It undergoes phosphorylation within the cell by the enzyme hexokinase and is converted to FDG-6-phosphate. FDG-6-phosphate is not further metabolized and gets trapped in the cell ➢ Cancer cells have increased anerobic glycolysis and decreased levels of glucose-6-phosphatase. Because of this, cancer cells limit further metabolism of the tracer in cancer cells ➢ PET-CT combines the functional information from a PET scan with the anatomical information from a CT scan. It can pinpoint the exact location of abnormal activity. It is used to evaluate patients with various cancers (e.g., including lung cancer and lymphoma)
PET/CT and PET/MRI	These are the hybrid devices which combine the PET and CT/MRI in the same setting giving improved quantification and image contrast

Tumor Markers

TABLE 14.16: Common tumor markers.

Tumor marker	*Associated tumors*
	1. Enzymes
Alkaline phosphatase (ALP)	Hepatoma, secondaries in liver, ovarian, lung, gastrointestinal cancers, and Hodgkin's disease
Placental alkaline phosphatase (PLAP)	Seminoma
Prostatic acid phosphatase (PAP)	Prostate carcinoma
Neuron-specific enolase (NSE)	Small-cell carcinoma of lung, neuroblastoma
Tartrate-resistant acid phosphatase (TRAP)	Hairy cell leukemia
	2. Hormones
Human chorionic gonadotropin (hCG)	Trophoblastic tumors, nonseminomatous tumors of testis
Calcitonin	Medullary carcinoma of thyroid
Catecholamine	Pheochromocytoma
Ectopic hormones	Paraneoplastic syndromes (*see* **Table 14.32**)
	3. Oncofetal antigens
Alpha-fetoprotein	Cancer of liver, nonseminomatous germ cell tumors of testis
Carcinoembryonic antigen (CEA)	Carcinomas of the colon, pancreas, lung, and stomach. May also be elevated in cigarette smoking, peptic ulcer disease, inflammatory bowel disease, pancreatitis, hypothyroidism, cirrhosis, and biliary obstruction
	4. Carbohydrate markers/mucins and other glycoproteins
CA-125	Ovarian cancer
CA 15-3	Breast carcinoma, pancreatic, lung, ovarian, colorectal and liver cancer in some benign breast and liver diseases
CA 19-9	Pancreatic and colorectal cancer
	5. Specific proteins
Immunoglobulins	Multiple myeloma and other gammopathies
Prostate-specific antigen (PSA)	Prostate carcinoma. Other conditions include prostatitis, benign prostatic hypertrophy, prostatic trauma and after ejaculation
Ferritin	Nonspecific, Hodgkin's lymphoma, leukemia, liver, lung, and breast cancer
Thyroglobulin	Differentiated thyroid cancer
S-100	Melanoma
Inhibin A and B	Granulosa cell tumor
Catalase, profilin-1, CD59	Oral squamous cell carcinoma
	6. Receptor markers
Estrogen and progesterone receptors	Breast cancer as indicators for hormonal therapy
C-erbB2 (HER-2 Neu)	Coreceptor in epidermal growth factor action, overexpression associated with cancer
	7. Genetic changes
Bcr-Abl mutation	Chronic myeloid leukemia
	8. New molecular markers
p53, APC, RAS mutants in stool and serum	Carcinoma colon
p53 and RAS mutants in sputum and serum	Lung cancer
	9. Mitochondrial markers
mtDNA	Carcinoma breast, prostate, lung, thyroid, colon

Staging of Cancer

Q. RT1.3 **Enumerate, describe and discuss classification and staging of cancer (AJCC, FIGO, etc.).**

Staging System

Cancer is often staged twice. The first rating is done before treatment and is called the clinical stage. The second rating is done after treatment, such as surgery, and is called the pathologic stage. The pathologic stage is more precise the extent of the cancer.

TNM Staging System

- The TNM staging system is most common method used for cancer staging.
- It is maintained by American Joint Committee on Cancer (AJCC) and Union for International Cancer Control (UICC).

TABLE 14.17: TNM staging system.

T = Tumor	➢ The T score is a rating of the extent of the primary tumor ➢ T scores are based on the presence, size, and extension of the primary tumor – TX = primary tumor cannot be assessed – T0 = no primary tumor (It is possible to have cancer but not have a primary tumor) – Tis = there are abnormal or cancer cells without breaching the deeper layers (tumor in situ) – T1, T2, T3 there is and T4 are based on the primary tumor's size, extension, or both (varies with type of cancer)
N = Nodes	➢ The N category reflects the extent of cancer within nearby lymph nodes ➢ N scores are based on whether there is cancer in nearby lymph nodes and the number or region of nodes with cancer – NX = lymph nodes cannot be assessed – N0 = no cancer was found in the lymph nodes – N1, N2, and N3 scores are based on the number of nodes with cancer or which nodal groups have cancer (varies with type of cancer)
M = Metastasis	➢ The M category tells you if the cancer has spread to distant sites ➢ M0 means there is no cancer in distant sites ➢ M1 means there is cancer in distant sites

- In this system, the letters T, N, and M describe a different area of cancer growth **(Table 14.17)**.
- Not all cancers are rated by TNM scores (exceptions include hematological cancers).

Stage Groups

- Each type of cancer has its own stage groups based on where the cancer has grown and spread. There are either four or five stage groups per cancer (ranked by Roman numerals starting with either stage 0 or stage I and end at stage IV).
- Stage groups for most cancers are defined by TNM scores. If TNM scores are not used, stage group are still defined by where the cancer is in the body. Some cancers that are grouped by TNM scores also use other information to define the stage groups.
- All people who meet the criteria of a stage group have a similar prognosis.
- In general, cancers that cannot spread to distant sites are rated as stage 0. Stage I includes small primary tumors that have not spread to lymph nodes. Stage II and III are larger or more extensive primary tumors with or without cancer in nearby lymph nodes. Stage IV is cancer that has spread to distant sites at diagnosis.

TABLE 14.18: FIGO staging of gynecological cancers.

FIGO staging	
Stage 0	Carcinoma in situ
Stage I	Confined to the organ of origin
Stage II	Invasion of surrounding organs or tissue
Stage III	Spread to distant nodes or tissue within the pelvis
Stage IV	Distant metastasis(es)

FIGO Staging System (Table 14.18)

It is determined by the International Federation of Gynecology and Obstetrics and used for gynecological cancers. In general, there are five stages.

Performance Status

Performance status is a measure of a patient's functional capacity. It has consistently been found to predict survival in patients with cancer, and it is used in that capacity as an entry criterion and an adjustment factor for clinical trials of anticancer therapies. A number of metrics have been developed to quantify performance status; among them, the Eastern Cooperative Oncology Group (ECOG) performance status **(Table 14.19)** and Karnofsky performance status (KPS) **(Table 14.20)** are the most commonly used.

TABLE 14.19: Eastern Cooperative Oncology Group (ECOG) performance status.

Status	***Definition***	
0	Fully active Able to carry on all predisease performance without restriction	
1	Restricted in physically strenuous activity but ambulatory Able to carry out work of a light or sedentary nature, for example, office work	
2	Ambulatory and capable of all self-care; unable to carry out any work activities	Up and about more than 50% of waking hours
3	Capable of only limited self-care	Confined to bed or chair more than 50% of waking hours
4	Cannot carry on any self-care. Completely disabled	Totally confined to bed or chair
5	Dead	

TABLE 14.20: Karnofsky performance status (KPS).

Value	*Activity and assistance*	*Signs and symptoms*	*Care required*
100	Able to perform normal activity	No signs and symptoms of disease	Care for self
90	Able to perform normal activity	Minor signs and symptoms of disease	Care for self
80	Able to perform normal activity with effort	Some signs and symptoms of disease	Care for self
70	Unable to do normal activity	–	Care for self
60	Requires occasional assistance	–	Able to care for most of personal needs
50	Requires considerable assistance	–	Requires frequent medical care
40	Disabled and requires special assistance	–	Requires special care
30	Severely disabled	–	Requires hospitalization although death not imminent
20	Very ill	–	Hospitalization and active supportive care
10		Moribund	
0		Dead	

CANCER TREATMENT

Management of Cancer Patient

Q. IM13.6 Describe and distinguish the difference between curative, palliative, and hospice care in patients with cancer (Table 14.21).

Q. Demonstrate an understanding and needs and preferences of patients when choosing curative and palliative therapy.

Q. Describe the therapies used in alleviating suffering in patients at the end of life (palliative therapy, hospice and pain management).

Q. Write a short note on adjuvant and neoadjuvant chemotherapy.

TABLE 14.21: Difference between curative cancer therapy, palliative cancer therapy and hospice cancer care.

Curative therapy	*Palliative therapy*	*Hospice*
Primary objective of curative treatment is to treat the disease. It may be surgery, chemotherapy, radiotherapy, targeted therapy, immunotherapy, etc. It can be defined as the proportion of patients who survive beyond the time after which the risk of treatment failure approaches zero	Palliative care is care given to improve the quality of life of patients who have a serious or life-threatening disease, such as cancer Palliative care is an approach to care that addresses the person as a whole, not just their disease Palliative care is also called comfort care, supportive care, and symptom management Palliative care can be provided either in the hospital or an outpatient clinic or a long-term care facility, or at home under the direction of a physician	Hospice is a special type of care in which medical, psychological, and spiritual support are given to patients and their loved ones when cancer therapies are no longer controlling the disease. A person's cancer treatment continues while one is receiving palliative care, but with hospice care, the focus has shifted to just relieving symptoms and providing support at the end of life The goal of hospice care is to help you live each day to the fullest by controlling pain and other symptoms, making you as comfortable as possible. It is not intended to either hasten or postpone death. The focus is on caring, not curing. If your condition improves or your cancer goes into remission, hospice care can stop and active treatment can resume

Precision medicine (also known as personalized medicine) is an emerging approach for disease treatment and prevention that takes into account individual variability in genes, environment, and lifestyle for each person.

Surgery	➢ Surgical resection is often performed with curative intent, although selected patients may benefit from palliative surgery that is performed for debulking large tumor masses (e.g., ovarian cancer), increasing the efficacy of immunotherapy [e.g., renal cell carcinoma (RCC)], or relieving symptoms (e.g., mastectomy for local control in a patient with metastatic disease). ➢ Surgery can facilitate staging and guide subsequent therapeutic decisions (adjuvant treatment), including chemotherapy or radiation therapy. ➢ Surgical resection of isolated or oligometastatic sites in selected patients can improve survival. Examples include solitary brain metastases, pulmonary metastases from sarcomas, and liver metastases from colorectal cancer.
Chemotherapy (Tables 14.22 to 14.28)	➢ Cytotoxic chemotherapy targets all dividing cells and has broad toxicities. ➢ In patients with resectable disease, chemotherapy may be used before the surgery **(neoadjuvant)** or following complete resection **(adjuvant).** ➢ Chemotherapy is typically given in cycles of 2–4 weeks. In most regimens, IV treatment is given on the first few days of the cycle, with no further treatment until the next cycle. In other regimens, treatments are administered weekly for 2–3 weeks, with 1 week off between cycles. ➢ **Curative** intent chemotherapy includes neoadjuvant, adjuvant, and chemoradiation regimens in solid tumors. Chemotherapy alone is curative in many lymphomas, leukemias, and germ cell tumors. ➢ **Palliative** chemotherapy is used in advanced solid tumors and relapsed hematologic malignancies, with a focus on prolonging survival and improving the quality of life. ➢ Most agents have a very narrow therapeutic index, and dosing is based on body surface area (mg/m2). Chemotherapy toxicities are variable and can be life threatening.

Contd...

Contd...

<table>
<tr><td rowspan="1">**Radiotherapy**</td><td colspan="2">➢ Radiation is used for treatment of benign and malignant diseases. Commonly used forms of radiation include external-beam photons and electrons.
➢ Brachytherapy is an alternative method of radiation therapy, where radioactive sources are placed close to or in contact with their target tissue. Brachytherapy sources can be temporary or permanent.
➢ Radioactive substances can also be administered systemically. For instance, iodine-131 is administered orally for treating thyroid cancer, yttrium-90 microspheres are injected into the liver vasculature in hepatocellular cancer, and radium-223 is dosed intravenously in patients with prostate cancer and skeletal metastases.
➢ Radiation planning is designed to optimize precision doses of radiation to a tumor while sparing surrounding tissues.
➢ **Curative** intent radiotherapy is used in several settings.
➢ **Neoadjuvant:** Preoperative therapy intended to reduce both the extent of surgery and the risk of local relapse. Radiation in this setting is commonly administered in combination with chemotherapy.
➢ **Adjuvant:** Postoperative therapy intended to reduce the risk of local relapse.
➢ **Definitive:** High dose with curative intent.
➢ **Concurrent chemoradiation:** Chemotherapy with definitive radiation is associated with increased efficacy but at a cost of increased toxicity compared to either chemotherapy or radiation alone.
➢ **Palliative** radiotherapy is used in lower dosing to reduce symptoms, including bone pain, obstruction, bleeding, and neurologic symptoms.
➢ The total dose of radiation administered is usually divided over several days (fractionated). This allows time for normal tissue repair and increases the probability of delivering radiation to tumor cells in a radiosensitive phase of cell cycle. Radiation treatments are usually delivered either through conventional fractionation, hypofractionation, hyperfractionation, or accelerated fractionation schedules.
– **Conventional fractionation** consists of daily fractions typically of 1.8–2.0 Gy, usually delivered 5 days/week.
– **Hypofractionation** refers to the delivery of radiation divided into larger doses, with treatment once a day or less often.
– **Hyperfractionation** refers to the delivery of radiation divided into smaller doses per fraction, with treatments more than once per day.
– **Accelerated fractionation** is defined as reducing the overall duration of radiotherapy regimen without a significant change in the size of dose per fraction (by delivering more than 5 fractions/week)</td></tr>
<tr><td rowspan="10">**Hormonal therapy**</td><td>***Hormonal drugs***</td><td>***Indication***</td></tr>
<tr><td>**Glucocorticoids**</td><td>Combination therapy in lymphomas, brain tumors and spinal cord compression syndromes, prevention of chemotherapy-induced vomiting</td></tr>
<tr><td>**Adrenal inhibitor** *(mitotane)*</td><td>Adrenal carcinoma, Cushing's syndrome</td></tr>

<tr><td>**Progesterone**</td><td>Uterine cancer</td></tr>
<tr><td>**Targeted therapy (Table 14.29 and Fig. 14.4)**</td><td colspan="2">➢ The advent of molecularly targeted agents has led to marked advances in the treatment of selected malignancies.
➢ The most common classes of drugs are monoclonal antibodies and receptor tyrosine kinase inhibitors (TKIs).
➢ **Monoclonal antibodies (Table 14.30)** are administered IV and by standard nomenclature have names that end with the stem –mab. Subsystems indicate the source and target of the antibody. The most common source subsystems in oncology include –xi—indicating a chimeric antibody (e.g., cetuximab), –zu—indicating humanized antibody (e.g., bevacizumab), and –u—indicating fully human antibodies (e.g., ipilimumab). The most common target subsystems include –ci—indicating circulatory system (e.g., bevacizumab), –tu— indicating tumor (e.g., cetuximab), and –li—indicating immune system (e.g., ipilimumab).
➢ **TKIs** are administered orally and have names that end with –ib. The most common systems is –ti—indicating tyrosine kinase inhibition (e.g., imatinib).</td></tr>
<tr><td>**Immunotherapy**</td><td colspan="2">Artificial stimulation of the immune system to treat cancer.
Immunotherapies can be categorized as active, passive or hybrid (active and passive).
➢ Active immunotherapy directs the immune system to attack tumor cells by targeting tumor antigens.
➢ Passive immunotherapies enhance existing antitumor responses and include the use of monoclonal antibodies, lymphocytes, and cytokines.
Commonly used immunotherapy targets include:
➢ **Interleukin-2 (IL-2)** was the first immunotherapy approved for treatment of human cancers. IL-2 is a T-cell growth factor that allows for expansion of T cells while maintaining their functional activity [e.g., recombinant IL-2 (**aldesleukin**)].
➢ Programmed cell death–1 (PD-1) is a receptor expressed primarily on the surface of activated T cells. Binding of PD-1 to one of its ligands, PD-L1 or PD-L2, inhibits the cytotoxic T cell response. Tumor cells may co-opt this pathway to escape T cell-induced antitumor activity. The interaction between PD-1 and PD-L1 may be blocked by monoclonal antibodies against **PD-1** (nivolumab, pembrolizumab) or **PD-L1** (atezolizumab, durvalumab, avelumab). These immune checkpoint blockers have been approved for the</td></tr>

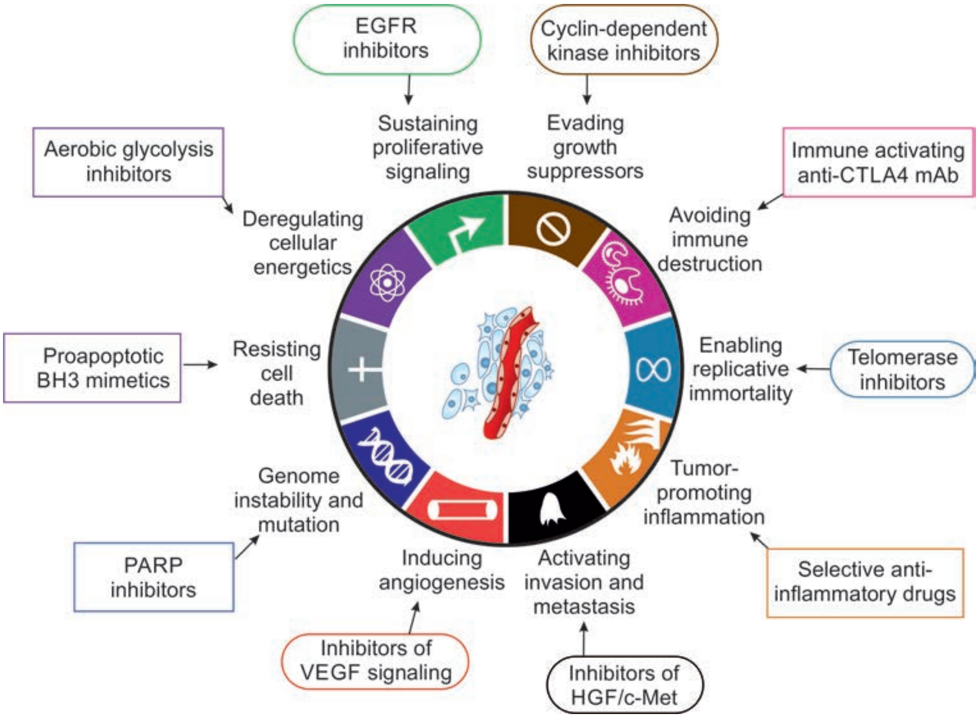
	treatment of multiple tumors including melanoma, lung cancer, bladder cancer, kidney cancer, head and neck cancer, and lymphomas. PD-L1 expression by immunohistochemistry (IHC) has been associated with response to anti-PD-1 or PD-L1 antibodies in some cancers. ➢ **Bispecific antibodies** (BITE cell—Bispecific T-cell Engagers) such as blinatumomab, which engage T cells to recognize cancer cells ➢ **Chimeric antigen receptor–T cells** (CAR-T cells) such as tisagenlecleucel and axicabtagene ciloleucel, which are specially engineered T cells capable of attacking tumor cells. They are approved for hematological malignancies derived from B cells (ALL and DLBCL) ➢ **CTLA4** is member of immunoglobulin superfamily expressed by activated T cells and results in inhibition of T reg cells. Drugs inhibiting CTLA4 include ipilimumab and tremelimumab.	
Cancer vaccines (therapeutic)	**Bacillus Calmette-Guérin (BCG) vaccine**	Live attenuated strain of *Mycobacterium bovis*, and it is given intravesically as a part to adjunctive therapy for superficial bladder cancer
	Sipuleucel-T	Dendritic cell-based cancer vaccine which enhance the T-cell response against prostatic acid phosphatase (used in castrate-resistant prostate cancer)
	GVAX	Composed of two irradiated prostate cancer cell lines that expresses granulocyte-macrophage colony-stimulating factor (GM-CSF) that promotes the activation of T cells with low affinity for self-antigens expressed by tumors
	Gp100 vaccine	Peptide vaccine with a melanocyte differentiation antigen, glycoprotein 100 (gp100). It is used in combination with high-dose IL-2 in patients with melanoma



EGFR inhibitors
Cyclin-dependent kinase inhibitors
Sustaining proliferative signaling
Evading growth suppressors
Aerobic glycolysis inhibitors
Immune activating anti-CTLA4 mAb
Deregulating cellular energetics
Avoiding immune destruction
Proapoptotic BH3 mimetics
Resisting cell death
Enabling replicative immortality
Telomerase inhibitors
Genome instability and mutation
Tumor-promoting inflammation
PARP inhibitors
Inducing angiogenesis
Activating invasion and metastasis
Selective anti-inflammatory drugs
Inhibitors of VEGF signaling
Inhibitors of HGF/c-Met

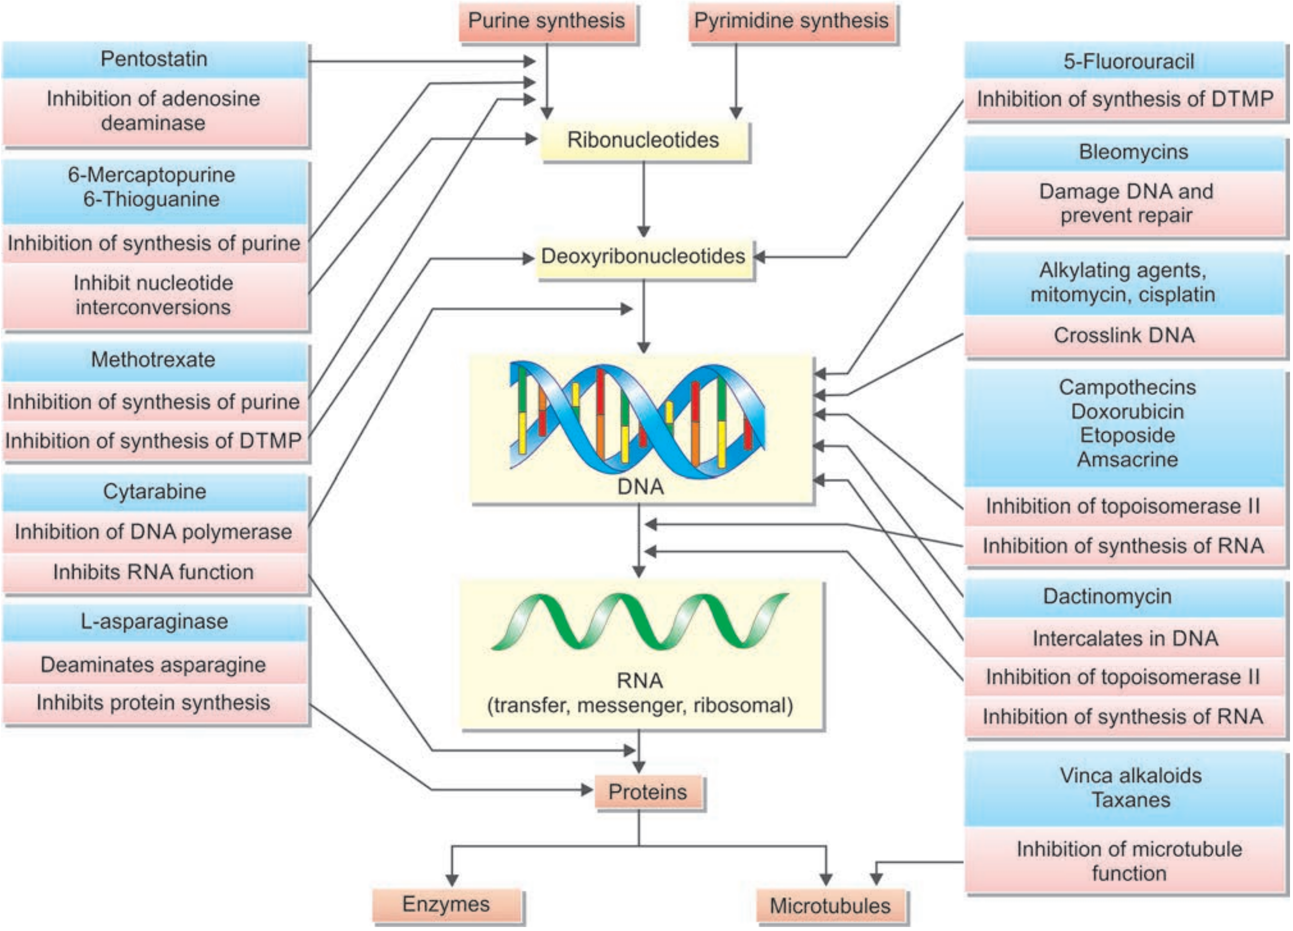
FIG. 14.4: Sites of targeted therapy.

Chemotherapeutic Agents

Q. Write a short note on classification of chemotherapeutic agents (Fig. 14.5).

TABLE 14.22: Classification of chemotherapeutic agents based on phase of cell cycle on which they act.

Cell cycle–specific drugs		***Cell cycle–nonspecific drugs***
These are effective when the cells are proliferating and act at specific phase of cell cycle		These are effective whether cells are dividing or in resting phase and can effect at any phase of cell cycle
Etoposide	G1-S phase	Alkylating agents Platinum compounds Anthracyclines Camptothecins
Antimetabolites	S phase	
Bleomycin Etoposide	G2-M phase	
Vinca alkaloids Taxanes	M phase	



Purine synthesis
Pyrimidine synthesis
Pentostatin
Inhibition of adenosine deaminase
6-Mercaptopurine
6-Thioguanine
Inhibition of synthesis of purine
Inhibit nucleotide interconversions
Methotrexate
Inhibition of synthesis of purine
Inhibition of synthesis of DTMP
Cytarabine
Inhibition of DNA polymerase
Inhibits RNA function
L-asparaginase
Deaminates asparagine
Inhibits protein synthesis
Ribonucleotides
Deoxyribonucleotides
DNA
RNA
(transfer, messenger, ribosomal)
Proteins
Enzymes
Microtubules
5-Fluorouracil
Inhibition of synthesis of DTMP
Bleomycins
Damage DNA and prevent repair
Alkylating agents, mitomycin, cisplatin
Crosslink DNA
Campothecins
Doxorubicin
Etoposide
Amsacrine
Inhibition of topoisomerase II
Inhibition of synthesis of RNA
Dactinomycin
Intercalates in DNA
Inhibition of topoisomerase II
Inhibition of synthesis of RNA
Vinca alkaloids
Taxanes
Inhibition of microtubule function

FIG. 14.5: Mechanism of action of various chemotherapeutic drugs.

TABLE 14.23: Alkylating agents.

Alkylating agents		➢ *These drugs alkylate nucleophilic groups on DNA bases (N7 of guanine is most susceptible) which lead to crosslinking of bases, abnormal base pairing, and DNA strand breakage* ➢ *These are cell cycle nonspecific drugs acting on both resting and dividing cells, can affect any stage of cell division* ***Common side effects** of all alkylating agents (mnemonic: BAGS):* ➢ *Bone marrow suppression* ➢ *Alopecia* ➢ *Gastrointestinal distress* ➢ *Sterility* ➢ *Secondary leukemia (leukemia and myelodysplasias)*		
Drug		***Special points***	***Common indications***	***Common adverse effects***
Nitrogen mustard	**Cyclo-phosphamide**	It is prodrug activated in liver (by Cyt P450) to 4-hydroxycyclophophamide, phosphoramide mustard and acrolein. At low doses, it is a potent immunomodulator	➢ **As anticancer agent:** Breast cancer, soft tissue sarcomas, NHL ➢ **As conditioning** regimen in HSCT ➢ **As immunosuppressant** in nephrotic syndrome, SLE, RA, Wegener's granulomatosis, PAN and other systemic vasculitis refractory ITP	➢ **Hemorrhagic cystitis** due to degradation product acrolein. It can prevented by MESNA with adequate hydration and treatment is by steroids ➢ ***Cardiotoxicity*** ➢ Syndrome of inappropriate antidiuretic hormone secretion (SIADH)
	Ifosfamide	It is prodrug activated in liver (by CYP450) into ifosfamide mustard and acrolein	➢ Testicular cancers ➢ Bladder cancer ➢ Soft tissue sarcomas ➢ NHL	➢ **Hemorrhagic cystitis** due to degradation product acrolein. Drug used for prevention is MESNA, and drug used for treatment is Steroids ➢ ***Neurotoxicity*** ➢ SIADH

Contd...

Contd...

	Melphalan	Bifunctional alkylating agent that forms interstrand and intrastrand crosslinks with DNA, resulting in inhibition of DNA synthesis and function	➢ Multiple myeloma (as conditioning regimen prior to transplantation) ➢ Multiple myeloma (as palliative care)	➢ Dose limiting myelosuppression with nadir of 4–6 weeks
	Chlorambucil	Bifunctional alkylating agent. $T_{1/2}$ is 2–4 hours. It spares myelocytes	➢ CLL ➢ Lymphomas ➢ Waldenstrom's macroglobulinemia	➢ Hyperuricemia ➢ Pulmonary fibrosis ➢ Seizures
	Mechlorethamine	Forms both intrastrand and interstrand crosslinks. Potent vesicant (always infuse via new IV site)	➢ Lymphomas ➢ Intrapleural, intrapericardial and intraperitoneal treatment of metastatic diseases	➢ Hyperuricemia ➢ CNS toxicity ➢ Potent vesicant ➢ Secondary malignancies *(**AML**—with IV administration, **BCC or SCC** with topical application)*
Nitrosoureas	**Carmustine**	It is BCNU bis chloroethyl nitrous urea. Lipid soluble drug which crosses blood-brain barrier, reaching concentrations >50% of plasma	➢ Brain tumors ➢ Implantable BCNU—used in glioblastomas ➢ Lymphomas ➢ Multiple myeloma	➢ Hepatotoxicity with transient elevations of transaminases in around 90% patients within 1 week of therapy ➢ **Hepatic veno-occlusive disease** in around 15–20% ➢ Pulmonary fibrosis
	Lomustine	It is CCNU (chloroethyl cyclohexyl nitrosourea). Forms intrastrand crosslinking of DNA	➢ Brain tumors ➢ Lymphomas	➢ ILD and pulmonary fibrosis ➢ **Neurotoxicity**
	Streptozocin	Forms intrastrand crosslinks of DNA. Selectively targets pancreatic beta cells due to the glucose moiety	➢ Pancreatic islet cell tumors ➢ Carcinoid tumors	➢ Renal ➢ **Altered glucose metabolism**
Alkyl sulfonates	**Busulfan**	Bifunctional alkylating agent. Interacts with cellular thiol groups and nucleic acids to form DNA-DNA and DNA-protein crosslinks. Crosses blood-brain barrier and placental barrier	➢ CML ➢ Conditioning regimen during HSCT	➢ Interstitial pneumonitis ➢ Pulmonary fibrosis ➢ Hyperpigmentation of skin ➢ Hepatotoxic and can cause **hepatic veno-occlusive disease**
Triazines	**Procarbazine**	Hydrazine analog acting as alkylating agent. Weak MAO inhibitor. Crosses blood-brain barrier	➢ Lymphomas ➢ Brain tumor (adjuvant)	➢ To be **avoided with alcohol or tyramine**-containing foods ➢ To be **avoided in G6PD** deficiency individuals ➢ Flu-like syndrome ➢ CNS toxicity ➢ Interstitial pneumonitis
	Dacarbazine	Initially developed as a purine antimetabolite, but antitumor effect is by methylation of nucleic acids	➢ Metastatic malignant melanoma ➢ Hodgkin's lymphoma ➢ Soft tissue sarcomas ➢ Neuroblastoma	➢ Flu-like syndrome ➢ CNS toxicity ➢ **Potent vesicant**—pain and burning at the site of injection
	Temozolomide	Imidazotetrazine analog that is structurally and functionally similar to dacarbazine. Active compound is **MTIC**. Methylates guanine residues in DNA but do not crosslink DNA strands. Oral bioavailability is 100%. Crosses blood-brain barrier	➢ Brain tumors ➢ Metastatic melanoma	➢ Myelosuppression is dose limiting ➢ Photosensitivity ➢ Mild elevation of hepatic transaminases
Ethyleneamines	**Thio-TEPA**	Crosslinks DNA leading to inhibition of synthesis of DNA, RNA, and proteins	➢ HSCT for brain tumors ➢ Leptomeningeal metastasis (intrathecal)	➢ CNS—intracranial hemorrhage, seizures ➢ Hepatitis ➢ Contact dermatitis ➢ Hemorrhagic cystitis
	Hexamethylmelamine	Highest concentrations are attained in tissues with high fat content	➢ Ovarian cancer (advanced or recurrent disease)	➢ Neurotoxicity (may be reduced with vitamin B_6 supplementation) ➢ Flu-like syndrome

TABLE 14.24: Platinum compounds.

Platinum compounds	➢ *They have similar mechanism of action of alkylating agents* ➢ *They use platinum compounds instead of alkyl group to form dimers in DNA* ➢ *Covalently binds to DNA at N-7 position of guanine and adenine. Reacts with two different sites of DNA producing crosslinks (90% intrastrand links).* ➢ *Also binds to nuclear and cytoplasmic proteins resulting in cytotoxic effects.* ➢ *All are administered only by IV route.* ***Common adverse effects:*** ➢ *Nausea and vomiting* ➢ *Bone marrow suppression* ➢ *Ototoxicity, nephrotoxicity, and neurotoxicity*		
Drug	***Special points***	***Common indications***	***Common adverse effects***
Cisplatin	Highest concentrations in liver and kidneys. Hydration prior and postadministration of drug	➢ Testicular cancer ➢ Ovarian cancer ➢ Bladder cancer ➢ Head and neck cancer ➢ Esophageal cancer ➢ SCLC and NSCLC ➢ NHL ➢ Trophoblastic neoplasm	➢ ***Coomb's positive hemolytic anemia*** ➢ Nephrotoxicity (dose related and reversible; hypomagnesemia, hypocalcemia and hypokalemia are common) ➢ Neurotoxicity (sensory neuropathy) ➢ Ototoxicity (high frequency hearing loss and tinnitus) ➢ Ocular toxicity (optic neuritis, papilledema, and cerebral blindness) ➢ Nausea and vomiting (acute and delayed) ➢ **Vascular events like MI, CVA,** etc. ➢ Azoospermia, impotence, and sterility ➢ *SIADH*
Oxaliplatin	Third-generation platinum compound. Prolonged terminal half-life of 240 hours	➢ Colorectal cancer (in combination of 5-FU and leucovorin) ➢ Pancreatic cancer ➢ Gastric ➢ Gastroesophageal cancer	➢ Neurotoxicity: ***Acute toxicity***—sensory neuropathy occurs usually 1–3 days after therapy; ***Chronic toxicity***—dose dependent—proprioception and neurosensory function. As compared to cisplatin, oxaliplatin induced neuropathy is reversible and returns to normal within 3–4 months of discontinuation of therapy ➢ ***Autoimmune thrombocytopenia, AIHA, and TTP*** have also been reported ➢ Hepatotoxicity with sinusoidal injury seen ➢ ***RPLS—reversible posterior leukoencephalopathy*** is seen rarely
Carboplatin	Crosses blood-brain barrier and enters CSF	➢ Ovarian cancer ➢ Germ cell tumors ➢ Head and neck cancers ➢ SCLC and NSCLC ➢ Endometrial cancer	➢ Thrombocytopenia is more pronounced ➢ Nephrotoxicity (Peripheral neuropathy)

TABLE 14.25: Antimetabolites.

Antimetabolites		➢ *These drugs act in S phase of cell cycle* ➢ *Only dividing cells are responsive to these drugs* ➢ *They have additional immunosuppressive properties* ***Common adverse effects:*** ➢ *Myelosuppression* ➢ *Mucositis* ➢ *Allergy/skin rash*		
Drug		***Special points***	***Common indications***	***Common adverse effects***
Folic acid analogs (Requires intracellular polyglutamation by folyl polyglutamate synthase—FPGS for its cytotoxic activity. All of these are predominantly excreted by kidneys)	**Methotrexate**	Mechanism of action is by inhibition of DHFR (reducing folate levels), inhibition of de novo thymidylate synthesis, inhibition of de novo purine synthesis and incorporation of dUTP into DNA, resulting in inhibition of DNA synthesis and function. Drugs used to treat overdose are **leucovorin, thymidine and gucarpidase**	**As anticancer agent** ➢ Head and neck cancer ➢ Choriocarcinoma ➢ Osteogenic sarcoma ➢ ALL ➢ Primary CNS lymphoma **Noncancerous indications:** ➢ Rheumatoid arthritis ➢ Crohn's disease ➢ Abortion (MTP) ➢ Ectopic pregnancy ➢ Psoriasis	➢ Renal failure ➢ Liver toxicity ➢ Pneumonitis ➢ ***Chemical arachnoiditis*** ➢ Acute cerebral dysfunction ➢ Menstrual irregularities
	Pemetrexed	Mechanism of action is by inhibition of folate-dependent enzyme thymidylate synthase and DHFR. All the patients require **folic acid and vitamin B_{12} supplementation**	➢ NSCLC (note that pemetrexed is not to be used in SCLC) ➢ Mesothelioma	Hand foot syndrome Mucositis

Contd...

Contd...

	Pralatrexate	Mechanism is similar to methotrexate. Only IV route. All the patients require **folic acid and vitamin B_{12} supplementation**	➢ Peripheral T-cell lymphoma	➢ Myelosuppression ➢ Mucositis
Purine analogs	**6-MP**	Requires intracellular phosphorylation by enzyme HGPRT to the cytotoxic monophosphate form. MOA is mainly by inhibition of purine synthesis by inhibiting enzymes PRPP (phosphoribosyl pyrophosphate amidotransferase) and inhibition of DNA/RNA synthesis by incorporation of thiopurine triphosphate nucleotides. **Metabolized by xanthine oxidase in liver**	➢ ALL **Noncancerous indications:** ➢ Crohn's disease ➢ Ulcerative colitis	➢ Allopurinol inhibits xanthine oxidase and hence enhances toxicity of 6-MP ➢ Hepatotoxicity ➢ Mutagenic ➢ **Teratogenic** ➢ **Carcinogenic** ➢ Immunosuppression
	6-TG	Similar to 6-MP. But, **no need of dose adjustment with renal or hepatic failure. Not metabolized by xanthine oxidase** and hence no drug interaction with allopurinol	➢ ALL ➢ AML ➢ CML **Noncancerous indications:** ➢ Crohn's disease ➢ Ulcerative colitis ➢ Psoriasis	➢ Same as side effects of 6-MP
	Cladribine	Purine deoxyadenosine analog with **high specificity for lymphoid cells**. Antitumor activity on both dividing and resting cells. MOA **include DNA synthesis inhibition, depletion of NAD and induction of apoptosis**. Crosses blood-brain barrier. Usually given **as 7 day continuous IV infusion**	➢ Hairy cell leukemia ➢ Chronic lymphocytic leukemia (CLL) ➢ NHL (low grade)	➢ Immunosuppression ➢ **Fever (due to cytokine release)** ➢ Tumor lysis syndrome (**All patients should receive prophylactic allopurinol**)
	Fludarabine	Analog of arabinofuranosyl adenosine with **high specificity to lymphoid cells. Inhibits DNA chain extension, DNA polymerases alpha and beta, and promotes apoptosis**	➢ CLL ➢ NHL ➢ Cutaneous T-cell lymphoma	➢ **Autoimmune hemolytic anemia** ➢ **Drug-induced aplastic anemia** ➢ Immunosuppression with decrease in CD4 and CD8 cells ➢ **Fever (due to cytokine release)** ➢ **Tumor lysis syndrome**
	Clofarabine	MOA is similar to cladribine. Also, it inhibits **DNA polymerases alpha, beta, and gamma**	➢ Pediatric relapsed/ refractory ALL	➢ Immunosuppression ➢ **Capillary leak syndrome** ➢ Renal toxicity ➢ Liver toxicity ➢ Cardiac toxicity
Pyrimidine	**Fluorouracil (5-FU)**	Cell cycle-specific drug acting in S phase of cell cycle. Inhibits thymidylate synthase, DNA synthesis, and RNA translation. Active metabolites FdUMP, FdUTP, and FUTP highest concentration in GI mucosa, bone marrow, and liver. Penetrates third space fluid collections and crosses blood-brain barrier. 90% of drug cleared in urine and lungs. Leucovorin enhances the antitumor activity and toxicity	➢ GI malignancies ➢ Head and neck cancer ➢ Breast cancer ➢ Ovarian tumors ➢ Topical use for skin cancers	➢ Hand-foot syndrome (palmar-plantar erythrodysesthesia)—incidence can be reduced by prophylactic usage of vitamin B_6, Celecoxib and Nicotine patch ➢ Ocular problems (blepharitis, tear duct stenosis, conjunctivitis) ➢ Neurological symptoms ➢ Cardiac symptoms (chest pain with ECG changes)
	Capecitabine	Prodrug of 5 FU. It is activated into active form in liver and tumor tissue. **Contraindicated in DPD deficiency** (dihydropyrimidine dehydrogenase deficiency)	➢ Breast (metastatic) ➢ Colorectal cancers ➢ GI cancers	➢ Diltiazem can prevent capecitabine-induced **coronary vasospasm** and chest pain ➢ Hepatotoxicity
	Cytarabine	It is activated into active metabolite ara-CTP. Incorporation of ara-CTP results in chain termination and inhibition of DNA synthesis. Also it inhibits DNA polymerases alpha, beta, and gamma. Good CSF penetration	➢ AML ➢ ALL ➢ CML ➢ NHL ➢ Leptomeningeal carcinomatosis	➢ Hepatic dysfunction ➢ Acute pancreatitis ➢ **Ara-C syndrome** (allergic reaction in pediatric population—it is characterized by fever, myalgia, malaise, bone pain, skin rash, conjunctivitis, and occasional chest pain) ➢ Pulmonary complications ➢ Skin changes ➢ Eye toxicity (conjunctivitis and keratitis)

Contd...

Contd...

	Gemcitabine	It requires intracellular activation by deoxycytidine kinase to form active metabolite gemcitabine triphosphate. MOA is by inhibition of DNA polymerases alpha, beta, and gamma; alterations in RNA processing and mRNA translation	➢ Pancreatic cancer ➢ NSCLC ➢ Breast cancer ➢ Ovarian cancer ➢ Bladder cancer ➢ Lymphomas	➢ Flu-like syndrome ➢ Renal microangiopathy (HUS, TTP) ➢ Radiation recall dermatitis
	5-azacytidine	Converted into active metabolite azacitidine triphosphate, which is incorporated into RNA and DNA. Incorporation into DNA results inhibition of methyltransferases, which in turn leads to loss of DNA methylation and gene reactivation. Aberrantly silenced genes like tumor suppressor genes are reactivated	➢ MDS ➢ CMML	➢ Myelosuppression ➢ Peripheral edema ➢ GI toxicity ➢ Renal toxicity
	Decitabine	Converted into active metabolite decitabine triphosphate. MOA—similar to 5-azacytidine	➢ MDS	➢ Similar to 5-azacytidine

TABLE 14.26: Mitotic spindle inhibitors.

Mitotic spindle inhibitors		➢ They act at M phase of cell cycle ➢ Plant-derived alkaloids **Adverse effects:** ➢ Myelosuppression ➢ SIADH (vinca alkaloids) ➢ Vesicants (vinca alkaloids) ➢ Hypersensitivity, alopecia, and nail changes (especially Taxanes) ➢ Neuropathy (predominantly sensory neuropathy)		
Drug		***Special points***	***Common indications***	***Common adverse effects***
Vinca alkaloids Plant alkaloid derivatives (from *Catharanthus roseus)*	**Vincristine**	Inhibits tubulin polymerization, disrupting formation of microtubules during mitosis	➢ ALL ➢ Lymphomas ➢ Soft tissue sarcomas ➢ Wilms' tumor ➢ Neuroblastoma	➢ Constipation and paralytic ileus ➢ SIADH ➢ Azoospermia and amenorrhea
	Vinblastine	Same as vincristine	➢ Testicular tumors ➢ Hodgkin's lymphoma (ABVD regimen) ➢ Breast cancer ➢ Kaposi's sarcoma ➢ Renal cell carcinoma	➢ Raynaud's syndrome in combination with bleomycin ➢ Hypertension ➢ Vascular events—MI, stroke, and Raynaud's syndrome
	Vinorelbine	Semisynthetic alkaloid of Vinblastine	➢ NSCLC ➢ Breast cancer ➢ Ovarian cancer	➢ Similar to vinblastine ➢ Lesser incidence of vascular events
Taxanes	**Paclitaxel**	Enhances tubulin polymerization leading to inhibition of mitosis. It is radiosensitizing agent	➢ Ovarian cancer ➢ Breast cancer ➢ Lung cancer ➢ Esophageal cancer ➢ Head and neck cancer	➢ Cardiotoxicity (arrhythmias) ➢ Onycholysis
	Docetaxel	MOA is similar to paclitaxel	➢ Breast cancer ➢ NSCLC ➢ Prostate cancer ➢ Gastric cancer ➢ Head and neck cancers	➢ Fluid retention syndrome ➢ Brown discoloration of finger nails ➢ Vesicant
	Cabazitaxel	Binds to tubulin and promotes its assembly into microtubule while simultaneously inhibiting disassembly, thus inhibiting mitotic and interphase cellular functions	➢ Hormone-refractory metastatic prostate cancer	➢ Cardiac arrhythmias
Others	**Ixabepilone**	Binds directly to beta tubulin subunits on microtubule leading to inhibition of normal microtubule dynamics. Exhibits activity against drug-resistant tumors	➢ Metastatic taxane resistant breast cancer	➢ Hypersensitivity reactions ➢ Neurotoxicity ➢ Myalgias ➢ Fatigue

Contd...

Contd...

	Eribulin	Inhibits microtubule growth by sequestering tubulin in nonproductive aggregates with no effect on microtubule shortening. Active against taxane-resistant tumor lines	➢ Metastatic refractory breast cancer ➢ Metastatic liposarcoma	➢ QT prolongation ➢ Myelosuppression ➢ Peripheral neuropathy
	Estramustine	Nor-nitrogen mustard conjugate of estradiol without alkylating agent properties. Mainly works by inhibiting microtubule structure and function	➢ Hormone-refractory metastatic prostate cancer	➢ Gynecomastia ➢ Diarrhea ➢ Cardiovascular complications ➢ Skin rash

TABLE 14.27: Topoisomerase inhibitors.

Topoisomerase inhibitors		***Common adverse effects:*** ➢ ***Myelosuppression*** ➢ ***Alopecia***		
Drug		***Special points***	***Common indications***	***Common adverse effects***
Camptothecins	**Irinotecan**	Active form is SN-38 metabolite. Binds and stabilizes topoisomerase I and results in double-strand DNA breaks. Colorectal tumors have higher levels of topoisomerase I	➢ Colorectal cancer ➢ NSCLC ➢ SCLC	➢ Diarrhea* ➢ Asthenia ➢ Elevation of liver enzymes
	Topotecan	MOA—similar to irinotecan	➢ Ovarian cancer ➢ SCLC ➢ Cervical cancer	Microscopic hematuria Headache and myalgias
Epipodophyllotoxins	**Etoposide**	Cell cycle-specific agent with activity in late S and G2 phases. Inhibits topoisomerase II. Associated with early secondary malignancies (especially AML associated with t(11; 23) which develops within 2–3 years of treatment)	➢ Germ cell tumors ➢ SCLC ➢ NSCLC ➢ NHL and HL ➢ Gastric cancer	➢ Metallic taste ➢ Radiation recall skin changes
	Teniposide	MOA—similar to etoposide	➢ ALL (refractory state)	➢ GI side effects ➢ Hypotension ➢ Hypersensitivity

*Early-onset diarrhea which occurs withing 24 hours of therapy is due to cholinergic excess and managed by atropine, whereas late-onset diarrhea is managed with antimotility agents.

TABLE 14.28: Antitumor antibiotics.

Antitumor antibiotics		***Common adverse effects:*** ➢ ***Myelosuppression*** ➢ ***Cardiotoxicity (especially anthracyclines)**** ➢ ***Mucositis, nail changes, and alopecia*** ➢ ***Potent vesicants***		
Drug		***Special points***	***Common indications***	***Additional adverse effects***
Anthracyclines	**Doxorubicin**	Intercalates into DNA resulting in inhibition of DNA synthesis and function. Inhibits topoisomerase II and also results in formation of cytotoxic oxygen-free radicals. Also inhibits DNA-dependent RNA polymerases	➢ Breast cancer ➢ HL and NHL ➢ Soft tissue sarcomas ➢ Ovarian cancer ➢ SCLC and NSCLC ➢ Wilms' tumor ➢ Neuroblastoma ➢ ALL	➢ Hyperpigmentation ➢ Radiation recall phenomenon ➢ Red-orange discoloration of urine
	Daunorubicin	Similar to doxorubicin	➢ AML ➢ ALL	➢ Similar to doxorubicin
	Mitoxantrone	Similar to doxorubicin	➢ Hormone-refractory prostate cancer ➢ AML ➢ Breast cancer ➢ NHL	➢ Blue discoloration of fingernails and sclera ➢ Secondary AML
Others	**Dactinomycin**	Preferentially binds to guanine-cytosine base pairs. Formation of oxygen-free radicals results in single- and double-stranded DNA breaks and subsequent inhibition of DNA synthesis and function	➢ Rhabdomyosarcoma ➢ Germ cell tumors ➢ Wilms' tumor ➢ Ewing's sarcoma ➢ Gestational trophoblastic diseases	➢ Hyperpigmentation ➢ Radiation recall syndrome

Contd...

Contd...

	Bleomycin	Contains DNA-binding region and iron-binding region. Iron is absolutely necessary as cofactor for free radical generation and bleomycin cytotoxic activity. It causes single- and double-stranded DNA breaks	➢ HL and NHL ➢ Germ cell tumors ➢ Head and neck tumors ➢ SCC of skin, cervix, and vulva	➢ Maintain a low FiO_2 in order to avoid pulmonary toxicity ➢ Skin reactions ➢ Pulmonary toxicity ➢ Hypersensitivity inform of fever and chills ➢ Vascular events (MI, stroke, Raynaud's phenomenon, etc.)
	Mitomycin	Acts as alkylating agent crosslinking DNA and also inhibits DNA-dependent RNA polymerase	➢ Gastric cancer ➢ Breast cancer ➢ Superficial bladder cancer ➢ Anal cancer ➢ Head and neck cancer	➢ Hemolytic uremic syndrome/MAHA ➢ Interstitial pneumonia ➢ Hepatic veno-occlusive disease ➢ Chemical cystitis and bladder contraction

***Cardiotoxicity:** Acute cardiotoxicity—myocarditis, pericarditis, arrhythmias; chronic cardiotoxicity—dilated cardiomyopathy; risk of cardiotoxicity increases with cumulative dose of >450 mg/m^2.

Targeted Therapy

Q. Write short essay/note on various types of targeted therapy in cancer patients.

TABLE 14.29: Targeted therapy agents.

Group	*Drug*	*Common indications*
Anaplastic lymphoma kinase (ALK) inhibitors	**Alectinib**	NSCLC
	Ceritinib	NSCLC
	Crizotinib	NSCLC
BCL2 inhibitors	**Venetoclax**	CLL with 17p deletion
BCR-ABL inhibitors	**Bosutinib**	CML
	Dasatinib	CML, Ph+ ALL
	Imatinib	CML, GIST, Dermatofibrosarcoma protuberans, MDS, ALL Ph+
	Nilotinib	CML
	Ponatinib	CML (T315I mutant)
BRAF, MEK inhibitors	**Cobimetinib**	Melanoma
	Dabrafenib	Melanoma
	Trametinib	Melanoma
	Vemurafenib	Melanoma
BTK inhibitors	**Ibrutinib**	Mantle cell lymphoma, CLL, Waldenström's macroglobulinemia
Cyclin-dependent kinase (CDK) 4/6 inhibitors	**Palbociclib**	ER-positive, HER2-negative advanced breast cancer
Epidermal growth factor receptor (EGFR) inhibitors	**Afatinib**	Metastatic NSCLC
	Erlotinib	Locally advanced or metastatic NSCLC pancreatic cancer
	Gefitinib	Metastatic NSCLC
	Osimertinib	Epidermal growth factor receptor (EGFR) T790M mutation-positive NSCLC
Histone deacetylase (HDAC) inhibitors:	**Belinostat**	Relapsed or refractory peripheral T-cell lymphoma
	Panobinostat	Multiple myeloma
	Romidepsin	Cutaneous T-cell lymphoma (CTCL), peripheral T-cell lymphoma (PTCL)
	Vorinostat	Cutaneous T-cell lymphoma
Human epidermal growth factor receptor 2 (HER2) inhibitors	**Lapatinib**	Breast cancer
	Neratinib	Breast cancer
Janus-associated kinase (JAK) inhibitors	**Ruxolitinib**	Myelofibrosis, polycythemia vera
Mammalian target of rapamycin (mTOR) inhibitors	**Everolimus**	HER2-negative breast cancer, PNET, NET, RCC, renal angiomyolipoma
	Temsirolimus	Advanced renal cell carcinoma
Poly (ADP-ribose) polymerase (PARP) inhibitors	**Olaparib**	BRCA-mutated advanced ovarian cancer and breast cancer
	Rucaparib	BRCA-mutated advanced ovarian cancer and breast cancer
Phosphatidylinositol 3-kinase delta (PI3Kδ) inhibitors	**Idelalisib**	Relapsed CLL, in combination with rituximab, relapsed follicular B-cell NHL (FL), relapsed small lymphocytic lymphoma (SLL)
Proteasome inhibitors	**Bortezomib**	Multiple myeloma, mantle cell lymphoma
	Carfilzomib	Multiple myeloma
	Ixazomib	Multiple myeloma

Contd...

Contd...

Group	*Drug*	*Common indications*
Smoothened (SMO)/Hedgehog pathway inhibitors	**Sonidegib**	Locally advanced basal cell carcinoma (BCC)
	Vismodegib	Metastatic or locally advanced BCC
Vascular endothelial growth factor receptor (VEGFR) inhibitors	**Axitinib**	Advanced renal cell carcinoma
	Cabozantinib	Advanced renal cell carcinoma, medullary thyroid cancer
	Lenvatinib	Radioactive iodine refractory differentiated thyroid cancer; renal cell carcinoma
	Pazopanib	Advanced renal cell carcinoma, advanced soft tissue sarcoma
	Regorafenib	Metastatic colorectal cancer, metastatic GIST
	Sorafenib	Metastatic renal cell carcinoma; unresectable hepatocellular carcinoma
	Sunitinib	Metastatic renal cell carcinoma; GIST after progression on imatinib; progressive pancreatic neuroendocrine tumors

TABLE 14.30: Monoclonal antibodies.

Drug	*Target*	*Common indications*	*Adverse effects*
Ado-trastuzumab emtansine	HER2-targeted antibody-drug conjugate	Metastatic breast cancer	Hepatotoxicity, pneumonitis
Alemtuzumab	CD52	T-cell prolymphocytic leukemia; relapsed or refractory B-cell CLL	Significant immunosuppression
Atezolizumab	PD-L1	Urothelial carcinoma and nonsmall cell lung cancer	Immune-mediated adverse events such as pneumonitis, colitis, endocrinopathies, encephalitis, etc.
Bevacizumab	VEGF	Advanced colorectal cancer, nonsquamous NSCLC, glioblastoma, cervical cancer, ovarian cancer, fallopian tube cancer, primary peritoneal carcinoma	Thromboembolism Hypertension (severe in 15%), proteinuria, bleeding (especially epistaxis or GI)
Blinatumomab	Bispecific CD19-directed CD3 T-cell engager	Philadelphia chromosome-negative relapsed or refractory B-cell precursor ALL	Cytokine release syndrome
Brentuximab vedotin (Antibody-drug conjugate)	CD30-specific chimeric IgG1 antibody	Refractory Hodgkin's lymphoma and refractory systemic anaplastic large cell lymphoma	Myelosuppression Neuropathy
Cetuximab	EGFR (HER1, ErbB-1)	Metastatic colon cancer	Severe infusion reactions characterized by rapid onset of airway obstruction, hypotension, and/or cardiac arrest
Daratumumab	CD38	Multiple myeloma	Severe infusion reactions
Dinutuximab	Glycolipid GD2	Neuroblastoma	Severe infusion reactions, pain (severe neuropathic pain in the majority of patients; administer intravenous opioid prior to, during, and for 2 hours following completion of the infusion)
Elotuzumab	SLAMF7	Multiple myeloma	Severe infusion reactions
Ipilimumab	CTLA-4	Unresectable or metastatic melanoma	Immune-mediated adverse effects
Necitumumab	EGFR	NSCLC	Severe infusion reactions, hypomagnesemia
Nivolumab	PD-1	Unresectable or metastatic melanoma as a single agent or in combination with ipilimumab, metastatic NSCLC, advanced renal cell carcinoma, classical Hodgkin's lymphoma	Immune-mediated adverse events such as pneumonitis, colitis, endocrinopathies, encephalitis, hepatitis, nephritis
Obinutuzumab	CD20	CLL	Tumor lysis syndrome
Ofatumumab	CD20	CLL	Prolonged severe neutropenia
Panitumumab	EGFR	Metastatic colorectal cancer	Severe dermatologic toxicity
Pembrolizumab	PD-1	Metastatic melanoma, metastatic NSCLC	Immune-mediated adverse events such as pneumonitis, colitis, endocrinopathies, hepatitis, nephritis
Pertuzumab	HER2	HER2-positive metastatic breast cancer	Left ventricular dysfunction

Contd...

Contd...

Drug	***Target***	***Common indications***	***Adverse effects***
Ramucirumab	VEGFR2	Advanced gastric or gastroesophageal junction adenocarcinoma, metastatic NSCLC, metastatic colorectal cancer	Hemorrhage and GI perforation
Rituximab	CD20	CD20-positive, B-cell NHL, CLL, rheumatoid arthritis, microscopic polyangiitis, Wegener's granulomatosis	Severe mucocutaneous reactions, serious cardiac arrhythmias
Siltuximab	IL-6	Multicentric Castleman's disease (MCD)	Infections, pruritus, weight gain
Trastuzumab	HER2	Breast cancer, stomach cancer	Cardiomyopathy

The currently approved conjugated antibodies have been shown in **Box 14.1**.

Q. Write a short note on immunosuppressive drugs.

- These drugs inhibit cellular and/or humoral immunity response and have major role in organ transplantation and autoimmune diseases.
- List of immunosuppressive drugs useful in cancer management are enumerated in **Box 14.2**.

Box 14.1: Conjugated antibodies.

Conjugated antibodies currently approved

- Radio-conjugated antibodies
  - Tositumomab
  - Ibritumomab
  - Both used against refractory lymphomas
- Toxin-conjugated antibody
  - Gemtuzumab ozogamicin
  - Used against AML

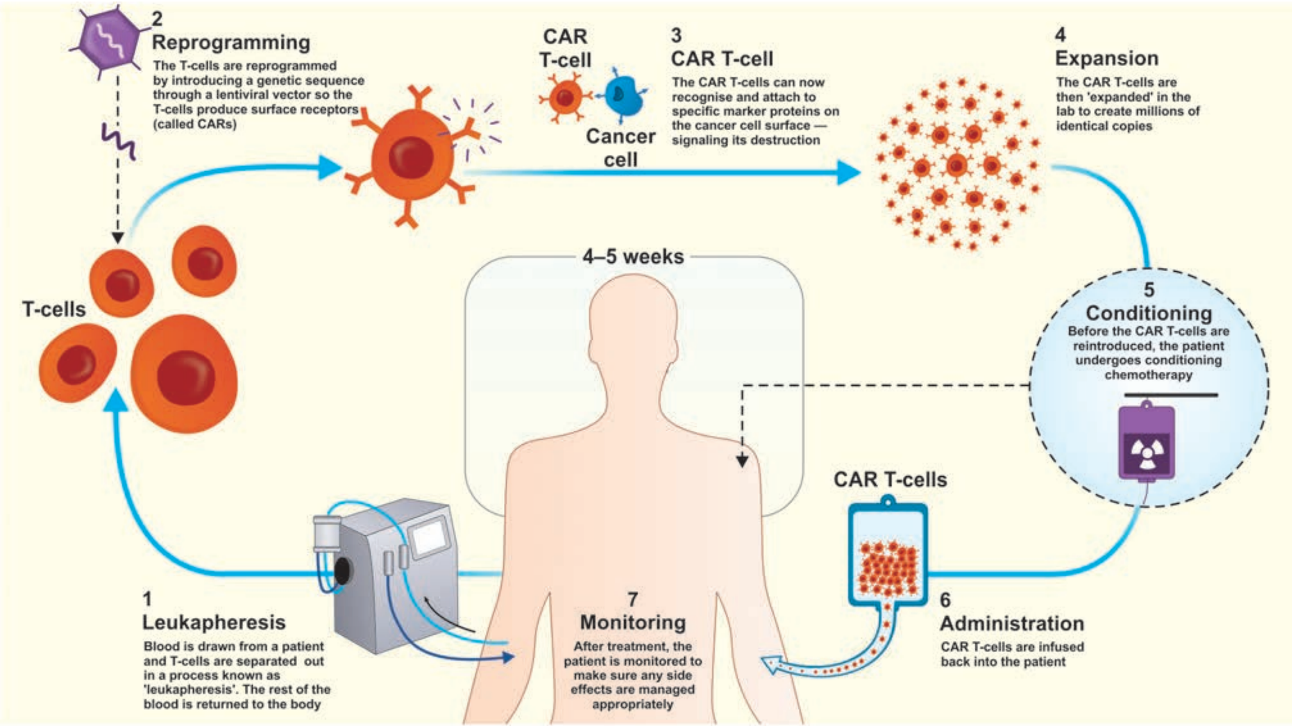
Box 14.2: Immunosuppressive drugs.

Immunosuppressive drugs

- Calcineurin inhibitors (specific R cell inhibitors): For example, cyclosporine, tacrolimus
- Antiproliferative drugs (cytotoxic drugs): Azathioprine, cyclophosphamide, methotrexate, chlorambucil, mycophenolate mofetil (MMF)
- Glucocorticoids: Prednisolone and others
- Antibodies: Muromonab CD3, antithymocyte globulin (ATG), Rho (D) immunoglobulin

Q. Write short notes on CAR-T Cell therapy.

- CAR T-cell therapy stands for chimeric antigen receptor T-cell therapy **(Fig. 14.6)**.
- It works by redirecting a patient's own immune cells (T-cells) in the laboratory, to directly identify and attack cancer cells. These modified T-cells are then returned to the patient where they can attack and destroy cancer cells.
- CAR T-cells have the potential to act as 'living drugs', providing long-term protection against relapse.



2
Reprogramming
The T-cells are reprogrammed by introducing a genetic sequence through a lentiviral vector so the T-cells produce surface receptors (called CARs)
CAR T-cell
Cancer cell
3
CAR T-cell
The CAR T-cells can now recognise and attach to specific marker proteins on the cancer cell surface — signaling its destruction
4
Expansion
The CAR T-cells are then 'expanded' in the lab to create millions of identical copies
T-cells
4–5 weeks
5
Conditioning
Before the CAR T-cells are reintroduced, the patient undergoes conditioning chemotherapy
CAR T-cells
1
Leukapheresis
Blood is drawn from a patient and T-cells are separated out in a process known as 'leukapheresis'. The rest of the blood is returned to the body
7
Monitoring
After treatment, the patient is monitored to make sure any side effects are managed appropriately
6
Administration
CAR T-cells are infused back into the patient

FIG. 14.6: CAR-T cell cancer therapy.

ONCOLOGIC EMERGENCIES

Q. Write short note on:

- **Emergency conditions related to tumors (Table 14.31).**
- **Clinical features and treatment of tumor lysis syndrome.**

Tumor Lysis Syndrome (TLS) (Fig. 14.7)

Tumor lysis syndrome (TLS) is treatment related complication. It can develop 1–5 days postchemotherapy treatment of leukemias and lymphomas.

- Metabolic triad of **hyperuricemia, hyperkalemia, hyperphosphatemia**.
- It can also lead to **renal failure and hypocalcemia** as secondary complications.
- It is due to release of the breakdown products of dying tumor cells. Chemotherapeutic agents cause cell lysis and cell death with release of intracellular components into the bloodstream.
- Breakdown of nucleic acid, catabolism of hypoxanthine and xanthine lead to elevated uric acid.
- Potassium and phosphate are present at high levels in cytoplasm.
- Risk factors are: Large tumor burden, high- growth fraction, increased pretreatment LDH or uric acid, or preexisting renal insufficiency.

TABLE 14.31: Oncologic emergencies.

Metabolic or hormonal problems	*Treatment related*	*Pressure or obstruction*
➢ Hypercalcemia ➢ Syndrome of inappropriate antidiuretic hormone secretion (SIADH) ➢ Lactic acidosis ➢ Hypoglycemia ➢ Adrenal insufficiency	➢ Tumor lysis syndrome ➢ Human antibody infusion reactions ➢ Febrile neutropenia ➢ Thrombocytopenia ➢ Pulmonary infiltrates ➢ Hemorrhagic cystitis ➢ Hyperviscosity syndrome ➢ Disseminated intravascular coagulation ➢ Hypersensitivity reactions to antineoplastic drugs	➢ Superior vena cava syndrome ➢ Epidural spinal cord compression ➢ Pericardial effusion/cardiac tamponade ➢ Intestinal obstruction ➢ Urinary obstruction

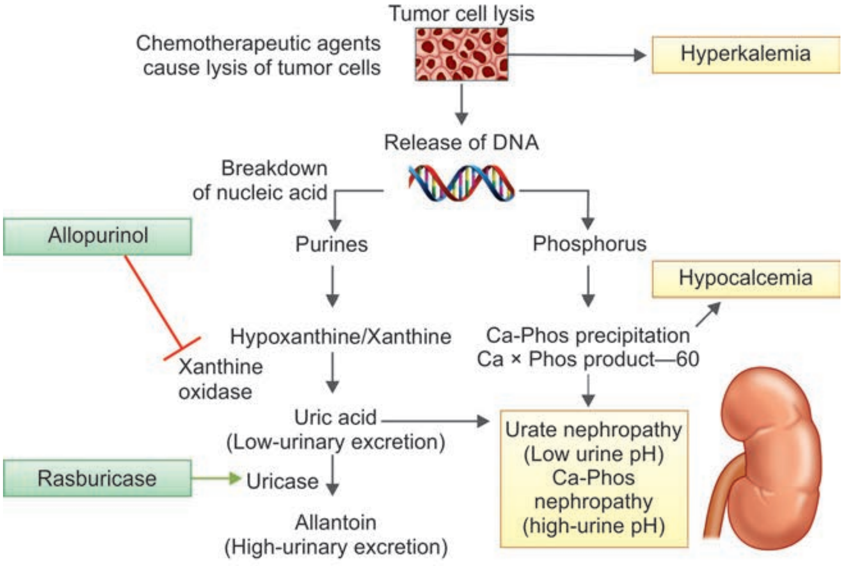
Clinical Features

Lysis of malignant cells causes several metabolic abnormalities/disturbances.

These include **hyperkalemia** (leads to cardiac arrhythmias), **hyperphosphatemia** (produces acute renal failure), **hyperuricemia** (produces acute renal failure), hyperuricosuria, **hypocalcemia** (results in seizures, muscle cramps, tetany, and arrhythmia), and consequent acute uric acid nephropathy and renal failure.

Prophylaxis

Patient at high risk: Leukemia, high-grade lymphoma, rapidly proliferating bulky solid tumor (e.g., small cell) must receive vigorous prehydration, allopurinol and careful metabolic monitoring.



Tumor cell lysis
Chemotherapeutic agents cause lysis of tumor cells
Hyperkalemia
Release of DNA
Breakdown of nucleic acid
Allopurinol
Purines
Phosphorus
Hypocalcemia
Hypoxanthine/Xanthine
Xanthine oxidase
Ca-Phos precipitation
Ca × Phos product—60
Uric acid
(Low-urinary excretion)
Urate nephropathy
(Low urine pH)
Ca-Phos nephropathy
(high-urine pH)
Rasburicase
Uricase
Allantoin
(High-urinary excretion)

FIG. 14.7: Mechanism of tumor lysis.

Febrile Neutropenia/Neutropenic Sepsis/Neutropenic Fever

Q. Write short essay/note on febrile neutropenia.

- Neutropenia (decrease of neutrophils below normal range) is a common complication of malignancy. It can occur secondary to chemotherapy, radiotherapy (if large amounts of bone marrow are irradiated) or as a component of pancytopenia due to infiltration of the bone marrow by malignancy.

Treatment: Intravenous hydration is of prime importance.

- **Rasburicase** (works for prevention and treatment)
  - Contraindicated in G6PD deficiency.
  - Rasburicase (recombinant urate oxidase) converts uric acid into allantoin, which is an inactive and soluble metabolite and is easily excreted by the kidneys.
- Alkalinization of urine to promote uric acid excretion is controversial (it may worsen hypocalemic tetany). Allopurinol can be used to decrease uric acid.
- Management of life-threatening hyperkalemia with antihyperkalemic measures.
- For hypocalcemia, infuse calcium gluconate under ECG monitoring. Hyperphosphatemia can be treated by giving aluminum hydroxide orally or hemodialysis.
- Early dialysis (hemodialysis is preferred) is required when uric acid >10 mg/dL, phosphorus >10 mg/dL or creatinine >10 mg/dL.

- Neutropenic fever is defined as a fever/pyrexia of 38.3°C for >1 hour in a patient with a neutrophil count <500/mm^3. The risk of sepsis is dependent on the severity and duration of neutropenia and the presence of other risk factors (e.g., intravenous or bladder catheters).

Clinical Features

- The typical presentation is with high fever. Neutropenic patients are prone to bacterial and fungal infection, most often from endogenous source (e.g., enteric bowel flora). Carefully examine for potential foci of infection. However, examination usually does not define the primary source of the infection. Signs and symptoms of infection may be minimal, particularly in patients receiving corticosteroids.
- Apart from fever, patients may also have nonspecific symptoms (e.g., nausea, diarrhea, drowsiness, breathlessness).
- Hypotension is a bad prognostic feature and may lead to systemic circulatory shutdown and organ failure.

Investigations

Full blood count, cultures (urine, sputum, stool depending on the case), chest X-ray, and swabs for culture (throat, central line, wound). Before antibiotic therapy, two sets of blood cultures from a peripheral vein and any indwelling venous catheters should be sent.

Treatment

Upon initial evaluation, each patient should be assessed for risk of complications from severe infection. Appropriate risk assessment may determine the type of empiric therapy (oral vs IV), duration of antibiotic therapy, and determination of inpatient versus outpatient management. Patients are classified into high-risk and low-risk groups. Multinational Association for Supportive Care in Cancer (MASCC) tool can also be used.

Low-risk group	*High-risk group*
➢ Anticipated brief (<7-day duration) period of neutropenia ➢ ANC >100/µL and absolute monocyte count >100/µL ➢ Normal findings on chest radiograph ➢ Outpatient status at the time of fever onset ➢ No associated acute comorbid illness ➢ No hepatic or renal insufficiency ➢ Early evidence of bone marrow recovery	➢ Anticipated, prolonged (>7-day duration), and profound neutropenia (ANC <100/µL) following cytotoxic chemotherapy ➢ Significant medical comorbidities, including hypotension, pneumonia, new-onset abdominal pain, or neurologic changes

- Antibiotics (**Flowchart 14.3**).
- **Antifungal:** If there is no response for antibiotics after 72–96 hours, treatment with amphotericin B or voriconazole should be given to cover fungal infection.
- **Growth factors:** G-CSF, GM-CSF are given to improve the blood counts.
- **Other supportive therapy:** Patients with signs of systemic illness, such as tachycardia, hypotension, oliguria require urgent admission and resuscitation with intravenous fluids to restore circulatory function. Other supportive therapy includes inotrope therapy, ventilation or hemofiltration.

Prophylactic fluoroquinolones

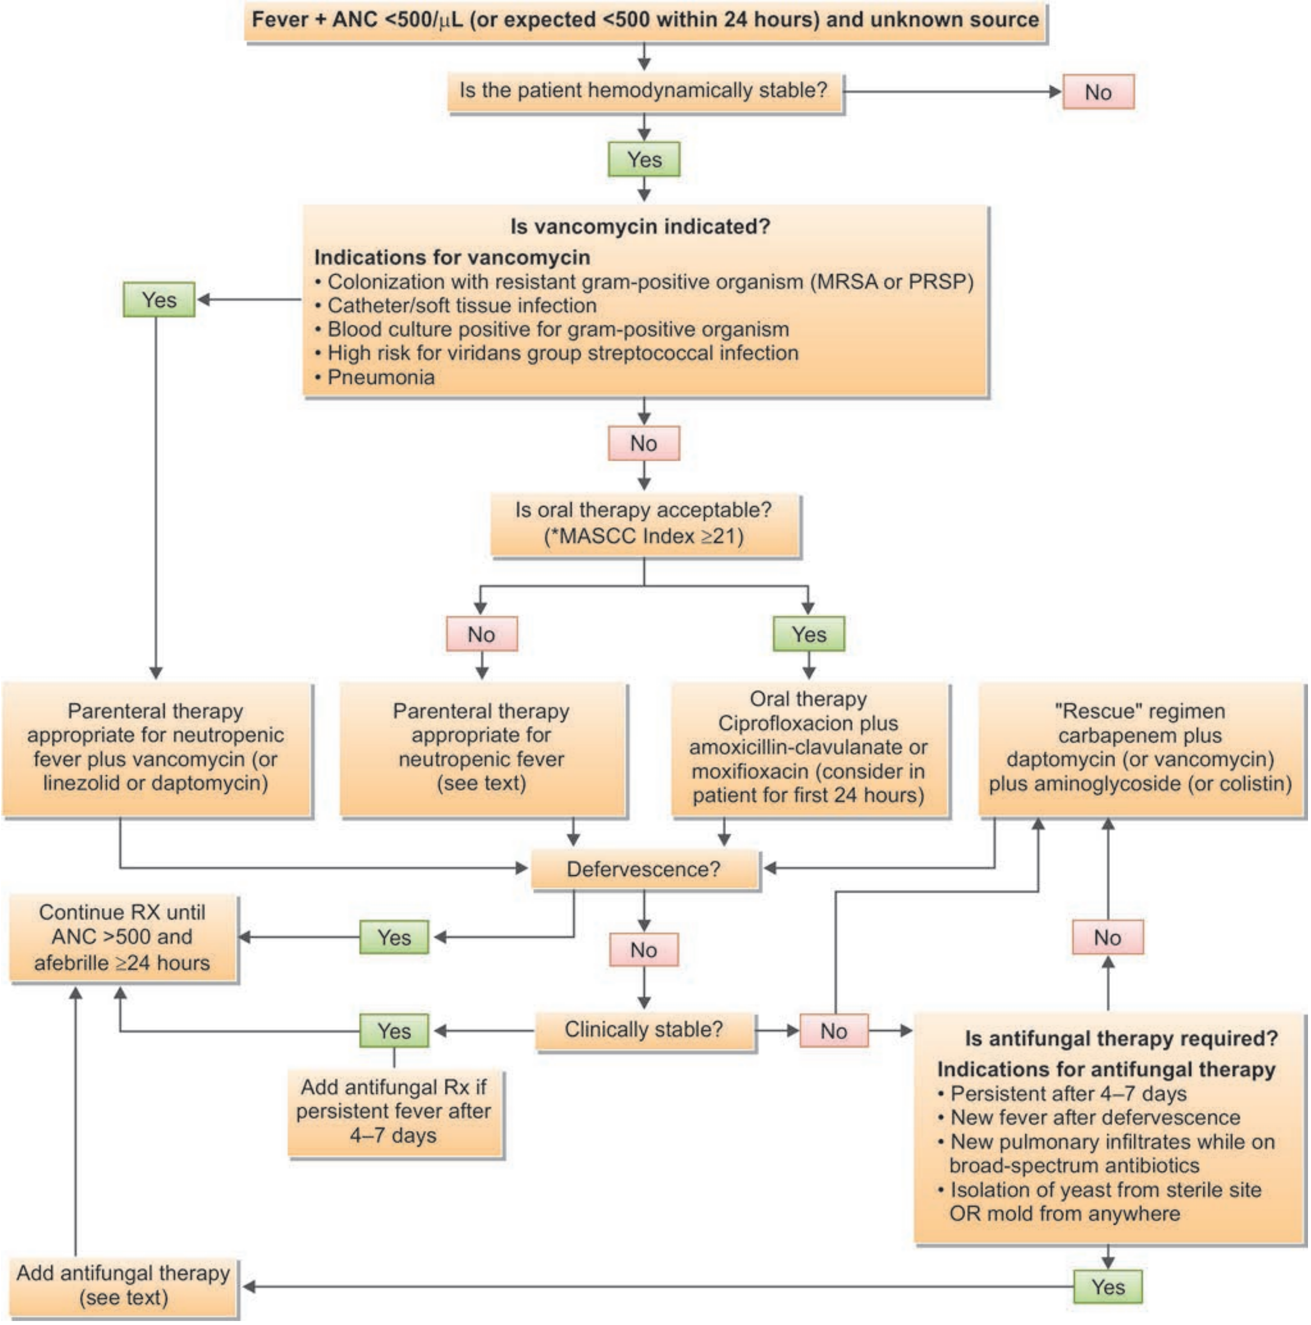
- It is given to high-risk and intermediate-risk groups (consists of patients receiving high-dose chemotherapy and those with hematological malignancy) in which the anticipated duration of neutropenia is >7 days.
- Prophylactic fluoroquinolones are not indicated in patients with solid tumors undergoing standard outpatient cyclical chemotherapy in which the anticipated duration of neutropenia is <7 days, because it may lead to microbial resistance.

PARANEOPLASTIC SYNDROMES

Q. Write a short essay/note on paraneoplastic syndromes.

Definition: Paraneoplastic syndromes are **symptom complexes in cancer patients** which are **not directly related to mass effects or invasion or metastasis or by the secretion of hormones indigenous to the tissue of origin**.

FLOWCHART 14.3: Algorithm for the antibiotic.



Fever + ANC <500/µL (or expected <500 within 24 hours) and unknown source
Is the patient hemodynamically stable?
No
Yes
Is vancomycin indicated?
Indications for vancomycin
• Colonization with resistant gram-positive organism (MRSA or PRSP)
• Catheter/soft tissue infection
• Blood culture positive for gram-positive organism
• High risk for viridans group streptococcal infection
• Pneumonia
Yes
No
Is oral therapy acceptable? (*MASCC Index ≥21)
No
Yes
Parenteral therapy appropriate for neutropenic fever plus vancomycin (or linezolid or daptomycin)
Parenteral therapy appropriate for neutropenic fever (see text)
Oral therapy Ciprofloxacion plus amoxicillin-clavulanate or moxifioxacin (consider in patient for first 24 hours)
"Rescue" regimen carbapenem plus daptomycin (or vancomycin) plus aminoglycoside (or colistin)
Defervescence?
Continue RX until ANC >500 and afebrille ≥24 hours
Yes
No
No
Clinically stable?
Yes
No
Add antifungal Rx if persistent fever after 4–7 days
Is antifungal therapy required?
Indications for antifungal therapy
• Persistent after 4–7 days
• New fever after defervescence
• New pulmonary infiltrates while on broad-spectrum antibiotics
• Isolation of yeast from sterile site OR mold from anywhere
Yes
Add antifungal therapy (see text)

*(MASCC: Multinational association for supportive care in cancer)

Frequency: Though they occur in 10–15% of patients, it is important because:

- **May be the first manifestation** of an occult neoplasm.
- **May be mistaken for metastatic disease** leading to inappropriate treatment.
- May present clinical problems which **may be fatal**.
- Certain tumor products causing paraneoplastic syndromes may be **useful in monitoring recurrence** in patients who had surgical resections or are undergoing chemotherapy or radiation therapy.

Some paraneoplastic syndromes, their mechanism, and common cancer causing them are listed in **Table 14.32**.

TABLE 14.32: Paraneoplastic syndromes.

Clinical syndromes	*Cause/mechanism*	*Associated cancer (example)*
	1. Endocrinopathies	
Cushing's syndrome	ACTH or ACTH-like substance	Small-cell carcinoma of lung (SCLC)
Syndrome due to inappropriate antidiuretic hormone secretion	Antidiuretic hormone or atrial natriuretic hormones	Small-cell carcinoma of lung
Hypercalcemia	Parathyroid hormone-related protein (PTHRP), TGF-α, TNF, IL-1	Squamous cell carcinoma of lung
		Renal carcinoma
Carcinoid syndrome	Serotonin, bradykinin	Bronchial carcinoid
Hypoglycemia	Insulin or insulin-like substance	Fibrosarcoma
Polycythemia	Erythropoietin	Renal carcinoma, hepatocellular carcinoma
	2. Neurologic (neuromyopathic) syndromes	
Cerebellar degeneration	Anti-Yo, Anti-Tr, Anti-Ri	Ovary, breast, uterus, Hodgkin's disease, SCLC
LEMS	Antivoltage-gated calcium channel	SCLC
Opsoclonus-myoclonus syndrome	Anti-Ri	Neuroblastoma, lung, breast
Sensory neuronopathy	Antineuronal nuclear antibody-3	SCLC
Stiff-man syndrome	Antiamphiphysin	Breast, SCLC
Retinal degeneration	Antirecoverin, antibipolar cells of the retina	SCLC, melanoma
Neuromyotonia	Antiamphiphysin	Thymoma
Limbic encephalitis	Anti-Ma proteins	SCLC
Encephalomyelitis	Anti-Hu	SCLC, testicular, breast
Dermatopolymyositis	—	SCLC, others
Multifocal encephalomyelitis/sensory neuronopathy	Anti-CV2/CRMP5	Lung, uterus, ovary
	3. Cutaneous syndromes	
Acanthosis nigricans	Immunological; secretion of epidermal growth factor	Carcinoma of stomach, lung, and uterus
Paraneoplastic pemphigus	Immunological	B-cell lymphoproliferative disorders (80%), CLL, Castleman, disease, thymoma
Dermatomyositis	Immunological	Bronchogenic, breast carcinoma
Sign of Leser-Trelat (Rapid increase in number and size of seborrheic keratosis)	Immunological	Adenocarcinoma (stomach, rectum, breast, lungs, colon)
Exfoliative dermatitis	Immunological	Lymphoma
Acquired diffuse palmoplantar keratoderma (Fig. 14.8)	Immunological	Cancers of breast, lung, stomach, and leukemia
Bazex syndrome (Acrokeratosis paraneoplastica) (Fig. 14.9)	Immunological	Squamous cell carcinoma of the upper aerodigestive tract
Pityriasis rotunda	Immunological	Hepatocellular, gastric and prostate cancer, leukemia, lymphoma
Paget's disease		Invasive breast carcinoma
Erythema gyratum repens	Immunological	Transitional carcinoma of the kidney and adenocarcinoma of lung, breast, and esophagus
Sweet's syndrome		Leukemia
Pyoderma gangrenosum		AML, CML, myeloma
Necrolytic migratory erythema		Glucagonoma
	4. Changes in osseous, articular, and soft tissue	
Hypertrophic osteoarthropathy and clubbing of the fingers	Not known	Bronchogenic carcinoma
	5. Vascular and hematologic syndromes	
Venous thrombosis (Trousseau's syndrome)	Tumor products like mucins which activate clotting	Pancreatic carcinoma
		Bronchogenic carcinoma

Contd...

Contd...

Clinical syndromes	*Cause/mechanism*	*Associated cancer (example)*
Disseminated intravascular coagulation	Procoagulant substance: Cytoplasmic granules (e.g., acute promyelocytic leukemia cells), or mucus (adenocarcinomas)	Acute promyelocytic leukemia, prostatic adenocarcinomas
Nonbacterial thrombotic endocarditis	Hypercoagulability	Advanced mucus-secreting adenocarcinomas
	6. Renal syndromes	
Nephrotic syndrome	Tumor antigens, immune complexes	Various cancers
	7. Amyloidosis	
Primary amyloidosis	Immunological (AL-amyloid light chain protein)	Multiple myeloma
Secondary amyloidosis	Amyloid associated (AA) protein	Renal cell carcinoma

(ACTH: Adrenocorticotropic hormone; IL: Interleukin; TGF: Transforming growth factor; TNF: Tumor necrosis factor)

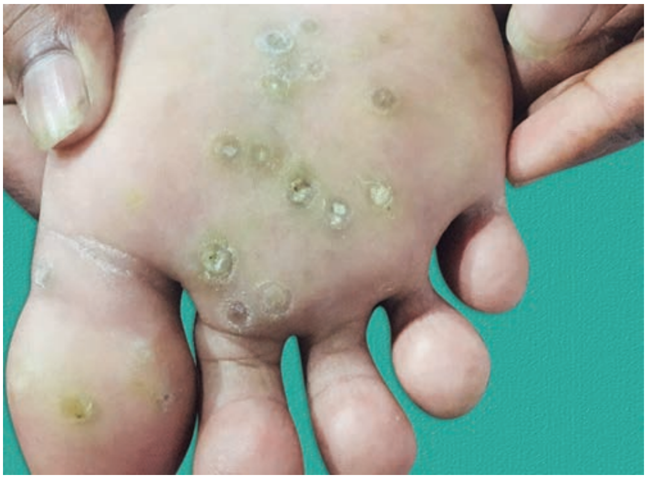


FIG. 14.8: Palmoplantar keratoderma.

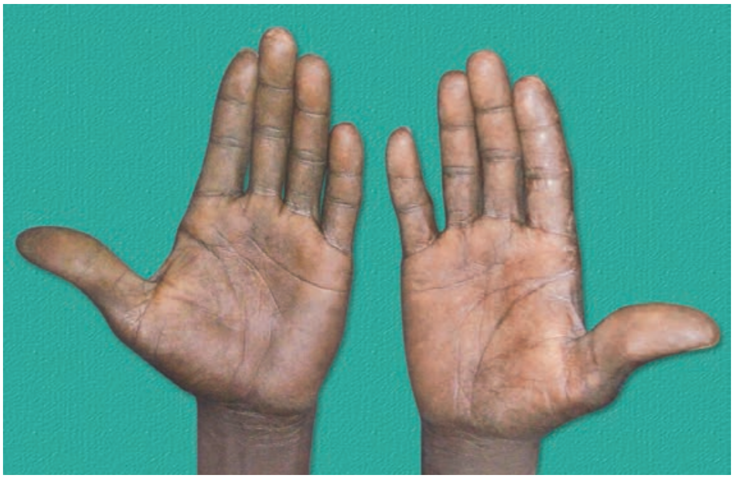

FIG. 14.9: Bazex syndrome.

Q. IM13.16 **Demonstrate an understanding and needs and preferences of patients when choosing curative and palliative therapy.**

Palliative Care

- *Palliative care* is a medical specialty, which does not aim for disease control, and will address the patient's physical and psychosocial symptoms and improve the quality of life **(Fig. 14.10)**.
- It is also appreciated that palliative care can be delivered concurrently with anticancer treatments, when there is scope to reduce the tumor burden and relieve distressing symptoms.
- Medical professionals should communicate this information and lay emphasis on securing effective palliation in relieving difficult symptoms, and helping patients maintain their dignity.
- Doctors should clearly convey to patients and families that inappropriate prolongation of treatment is undesirable.
- When a physician is of the opinion that cure is no longer an option, the decision of a patient to refuse further oncological treatment seems easier.

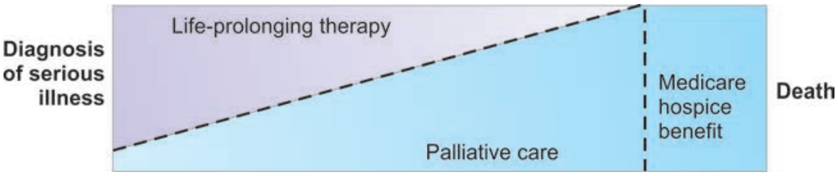

FIG. 14.10: Palliative care's place in the course of illness.

- The transition to palliative care becomes smooth when the doctors communicate the disease status and prognosis, the questions and emotions of patients and families are adequately answered, and a discussion about palliative care is done.
- For an improved patient-physician relationship, the values and wishes of a terminal-stage patient (and relatives) should be adequately evaluated by the medical team.

Overcoming the Barriers in Implementing a Transition

The shift in cancer care trajectory is not simple. The cancer patient does not always go through a conventional model of curative, palliative, and terminal phases of medical care. The boundaries are unclear in a clinical setting. It is difficult to find clear guidelines and it is noted that often there are no national standards for admission to palliative care. Hence, considerable delay occurs in referring a patient for palliative and end-of-life care.

There are several barriers to the medical community's effective implementation of a transition from curative to palliative care:
- Physician's inability to evaluate the futility of aggressive therapy
- Patient or relative does not want to stop anticancer treatment
- A reluctance to communicate the real situation of incurable stage
- Unavailability of palliative care facility and/or right drugs
- Cultural, linguistic and religious differences

Measures to overcome problem include:
- Cancer specialists and other health personnel dealing with chronic diseases should learn about the basics of palliative care
- Improve communication skills and enhance participation of patient/relative in medical decision-making
- Integrative model of healthcare system ranging from active treatment modalities to palliative care setup
- Identify medical, social, cultural, and geographic hurdles in developing palliative care.

In the Indian context, the socio-cultural aspects of a patient and family members become relevant while communicating the news about incurability, estimated prognosis and the shift of a medical goal from CDT to symptom alleviation and palliative care. Therefore, family members can receive the full medical information, whereas the patient receives information gradually and often partially, depending on their preferences.

Q. IM13.5 Describe the common issues encountered in patients at the end-of-life and principles of management.

Q. IM13.18 Describe and discuss the ethical and the medicolegal issues involved in end-of-life care.

Value of Medical Ethics

The four core values of medical ethics:
1. **Autonomy:** Patient has the right to choose or refuse the treatment
2. **Beneficence:** A doctor should act in the best interest of the patient
3. **Nonmaleficence:** First, do no harm
4. **Justice:** It concerns the distribution of health resources equitably.

Two more values of medical ethics are:
1. **Dignity:** The patient and the persons treating the patient have the right to dignity
2. **Truthfulness and honesty:** The concept of informed consent and truth telling.

CANCER PAIN

Q. IM13.17 Describe and enumerate the indications, use, side effects of narcotics in pain alleviation in patients with cancer.

Q. IM13.19 Describe the therapies used in alleviating suffering in patients at the end-of-life.

Definition

International Association for the Study of Pain, "An unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage":
- Clinical Assessment
- Careful history
- Evaluate psychological state
- Careful medical and neurologic examinations

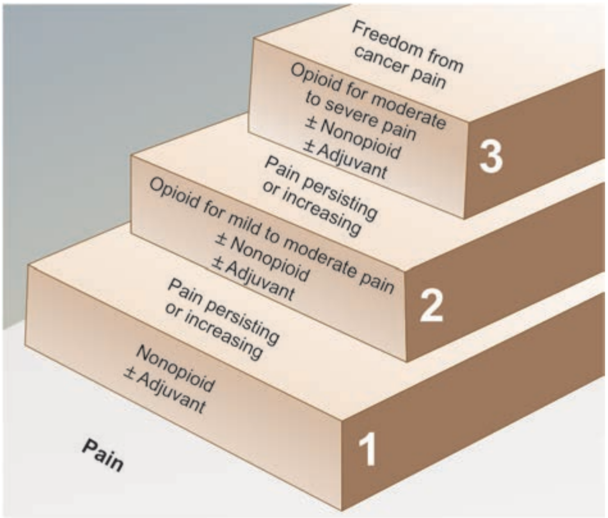
- Appropriate diagnostic studies
- Treat the pain
- Reassess response
- Discuss advance directives with the patient and family.

Types of Pain

Type	*Characters*	*Examples*	*Therapy*
Somatic	Well localized, constant, gnawing type	Bone metastasis	Anti-inflammatory agents, analgesics, tumor treatment (local radiation after feasibility assessment)
Visceral	Aching, associated with nausea	Pancreatic cancer	Nerve block
Neuropathic	Paroxysmal shock-like; burning/constricting	Plexopathy/postherpetic neuralgia	Analgesics, tumor treatment, nerve block
Sympathetic	Burning, squeezing with local edema	Reflex sympathetic dystrophy	Sympathetic blockade, physiotherapy, analgesics

Etiology

- Direct tumor involvement (70%): Invasion of bone, invasion or compression of neural structures, obstruction of hollow viscus or ductal system of solid viscus, vascular obstruction or invasion, mucous membrane ulceration or involvement.
- Cancer-induced syndromes (<10%): Paraneoplastic syndromes, pain associated with debility (e.g., bedsores, constipation, rectal or bladder spasms), other (e.g., postherpetic neuralgia)
- Diagnostic or therapeutic procedures (20%): Procedure-related pain (e.g., bone marrow aspiration or biopsy and lumbar puncture), acute postoperative pain or postsurgical syndromes (e.g., post-mastectomy, postthoracotomy), after radiation (e.g., injury to plexus or spinal cord, mucositis, and enteritis, after chemotherapy (e.g., mucositis, peripheral neuropathy).



Freedom from cancer pain
Opioid for moderate to severe pain ± Nonopioid ± Adjuvant
3
Pain persisting or increasing
Opioid for mild to moderate pain ± Nonopioid ± Adjuvant
2
Pain persisting or increasing
Nonopioid ± Adjuvant
1
Pain

FIG. 14.11: The ladder of cancer pain.

Comprehensive Assessment of Cancer Pain (Fig. 14.11)

- Detailed history of current pain problem
  - Catalogue of pain (number and locations)
  - Information for each pain:
    - Intensity (0–10)
    - Locations and radiation

      Assessment of characteristics of pain using , 'P Q R S T'

P: Provocative/palliative factors	What worsens the pain? What activities cause pain relief?
Q: Quality	How does it feel?
R: Radiation	Does it spread to any other part of the body?
S: Severity	How intense is the pain (measured using various pain rating scales), how does it affect your everyday activities?
T: Temporal factors	When is it present? Does it vary during the day and night?

    - Onset and changes over time
    - Temporal pattern (e.g., constant or intermittent) and quality (e.g., burning)
    - Exacerbating and relieving factors
    - Associated neurologic or vasomotor abnormalities
    - Other associated factors
    - How the pain interferes with the patient's life
    - Current therapeutic modalities (e.g., schedule, efficacy and adverse effects)
    - Prior therapeutic modalities (e.g., schedule, efficacy and adverse effects)
- Oncologic history:
  - Histologic type
  - Presentation: Date, stage, and sites of involvement

  - Antineoplastic therapies: Dates, types, doses, toxicities, and response to each therapy
  - Current sites of disease: Stable, responding, or progressive
  - Patient expectations and goals
- Medical history—may be affected by pain therapies:
  - Coexisting diseases
  - Medications and allergies
  - Substance abuse history
  - Other constitutional symptoms (e.g., anorexia, fatigue, sedation and other changes in mental status, nausea, vomiting, dysphagia, dyspnea, constipation, urinary and sexual function, depression, dry mouth, ability to take medications by mouth).
- Personal and social history:
  - Background: Age, education, employment, marital status, place of residence, religious affiliation, and cultural and ethnic background
  - Current status: Functional status, caregivers and their health and availability, support system
- Physical examination

Pain Scales

1. McGill pain questionnaire (MPQ)
2. Brief pain inventory (BPI)
3. Memorial pain assessment card (MPAC)
4. Memorial symptom assessment scale (MSAS)
5. Edmonton symptom assessment scale (ESAS)

Scaling of Pain (Wong-Baker FACES Pain Rating Scale) (Fig. 14.12)

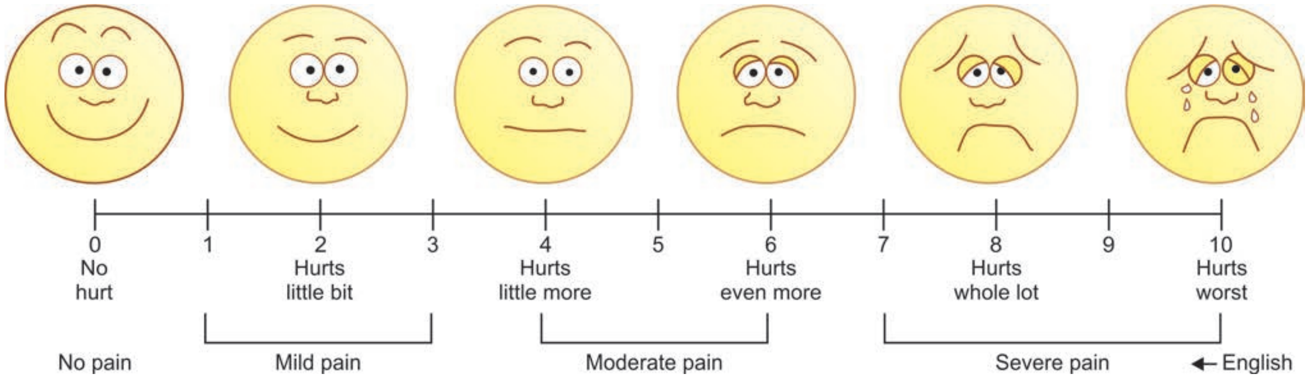


FIG. 14.12: Wong-Baker FACES pain rating scale.

Terminology

- **Physical dependence:** A normal physiologic response to chronic opioid administration characterized by development of the abstinence syndrome on abrupt withdrawal of opioids.
- **Tolerance:** A normal pharmacologic response to chronic opioid therapy characterized by the development of a relative resistance to analgesic and other effects of the drug overcome by increasing the dose administered.
- **Psychological dependence (addiction):** Abnormal behavior pattern characterized by an all-consuming desire to obtain opioids for reasons other than pain relief; this often occurs at the expense of the patient's physical, social, and environmental well-being.
- **Pseudoaddiction:** Seen in patients who are undertreated and in pain and are attempting to obtain appropriate analgesia.

TABLE 14.33: Levels of pain and management.

Level of pain	*Treatment recommended*	*Commonly used drugs*
Level 1 (mild pain)	Nonopioid ± adjuvant	Acetaminophen aspirin NSAIDs
Level 2 (mild to moderate pain)	Opioid ± nonopioid ± adjuvant	Opioids used are codeine, tramadol, etc.
Level 3 (moderate to severe pain)	Opioid ± nonopioid ± adjuvant	Opioid used are morphine, fentanyl, etc.

Cancer Pain Management (Table 14.33 and Fig. 14.13)

Pain is a highly prevalent symptom in patients with cancer. Adequate pain relief can be achieved in 90% of patients when treatment guidelines for cancer pain.

- Cancer pain is prevalent throughout the disease trajectory, yet undertreatment continues to be a significant problem.
- Clinical experience, research, and systematic reviews all demonstrate the efficacy of opioids in relieving cancer pain, particularly in the setting of advanced disease.
- Despite efficacy in relieving cancer pain, the long-term use of opioids is associated with previously unrecognized adverse effects, including endocrinopathy, neurotoxicity, sleep-disordered breathing, and, in some circumstances, misuse or abuse.
- In an aim to provide comfort, improve function, and limit adverse effects, multimodal interventions that include pharmacologic and nonpharmacologic therapies are needed to treat cancer pain.

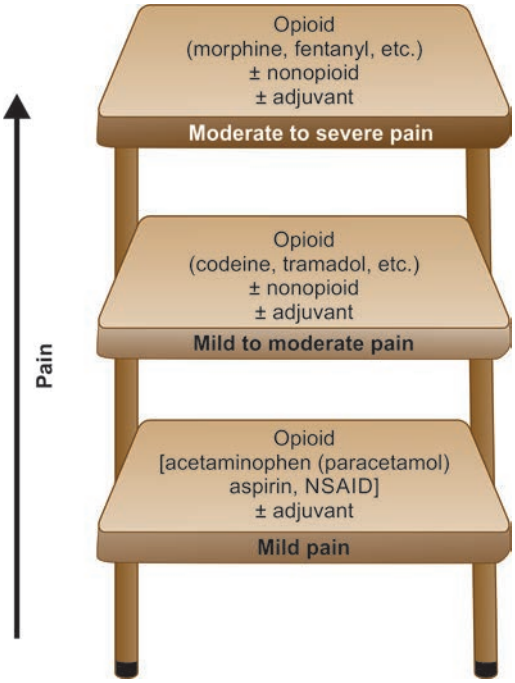

FIG.14.13: WHO pain ladder.

Before Opioids

1. NSAIDs:
    - Ibuprofen 200–800 mg Q6H
    - Naproxen 250–750 mg Q12H
    - Ketoprofen 50 mg Q6H
    - Oxaprozin 600–1,200 mg Q24H
    - Indomethacin 25–75 mg Q8H
    - Sulindac 150–200 mg Q12H
    - Diclofenac 50–75 mg Q8H
    - Piroxicam 10–20 mg Q24H
2. Selective COX-2 inhibitors:
    - Celecoxib 100–200 mg Q12H
    - Rofecoxib 50 mg Q24H
    - Meloxicam 7.5 mg Q24H
3. OPIODs:
    - Order opioids on a scheduled “around-the-clock” basis to optimize relief.
    - Order an as needed opioid to treat breakthrough or incidental pain.
    - Initiate a prophylactic bowel regimen at the same time opioids are prescribed. Patients usually require a combination of stool softeners and stimulant laxatives to treat opioid-induced constipation.
    - Treat opioid-induced nausea and vomiting with aggressive antiemetic management.
    - Once baseline opioid requirements are determined, sustained-release opioid preparations can be used to reduce the number of pills taken each day.
    - Teach the patient and family about the purpose and benefits of opioids to allay their fears about adverse effects and addiction.
    - Frequent assessment of pain relief is paramount during the opioid titration period.
    - Maximize the doses of one opioid before changing to another agent or route.

      For example, a patient taking 200 mg of controlled-release morphine every 12 hours and 200 mg of immediate-release morphine daily for breakthrough pain should have the dose of controlled-release morphine increased to 300 mg every 12 hours if he or she is not experiencing significant opioid adverse effects.
    - Avoid chronic administration of intramuscular or rectal opioids.

Opioid Drugs

Agent	Parenteral (IM, SC, IV) (mg)	Oral (mg)	Duration (h)	Half-life (h)	Comments
Morphine	10	30	3–6 (PO) 8–24 (SR) 3–4 (P) 4–5 (R)	2–4	Many formulations for individual patient needs Controlled-release formulations available with variable durations Caution with CrCl <30 mL/min because of accumulation of metabolite
Hydromorphone	1.5	7.5	3–4 (PO/P/R)	2–3	Good choice for subcutaneous administration because of potency Controlled-release formulation available

Contd...

Contd...

Agent	Parenteral (IM, SC, IV) (mg)	Oral (mg)	Duration (h)	Half-life (h)	Comments
Fentanyl	0.1	—	2–4 (TM) 0.5–4 (P) 48–72 (TD)	3–4	TD fentanyl 25 µg/h approximately equals 45 mg/day morphine (PO); TD has a slow onset and offset (12–24 hours); optimal dosing of TM products are found through titration and not through ATC dose of opioid Metabolized via CYP3A4
Oxycodone	—	20	3–4 (PO) 12 (SR) 4–6 (R)	2–3	No ceiling dose if given without nonopioid analgesics Metabolized to active metabolite, oxymorphone via CYP2D6 Multiple controlled-release formulations with various durations and additional agents (e.g., naloxone, acetaminophen)
Oxymorphone	1	10	4–6 (PO)	9–11	ER formulation with and without abuse deterrent technology available Food increases AUC; take on empty stomach
Levorphanol	—	2	4–8 (PO)	12–16	Inconsistent supply in recent years Accumulates with repeated administration, especially days 2–5
Methadone	5	10	6–8 (PO/P)	15–150	Despite a long half-life, duration of analgesia is not prolonged; however, drug accumulation can result in toxicities; caution is warranted when converting to methadone in patients with high opioid tolerance Metabolized via CYP3A4 and CYP2B6 Monitor Q-Tc
Hydrocodone	—	30	4–6	4	Available as fixed combination with acetaminophen or aspirin and single-agent controlled-release formulation
Codeine	100	200	3–4 (PO/P)	2–4	10% of the population lack the enzyme needed to metabolize codeine to its active metabolite morphine Metabolized via CYP2D6 Polymorphisms may increase toxicity
Tramadol	100	120			Prodrug Metabolized via CYP2D6; profound effect in rapid metabolizers Serotonin reuptake inhibition Controlled-release formulation available Maximum doses 400 mg/day IR; 300 mg/day ER Caution in patients with seizures Risk of serotonin syndrome
Tapentadol	—	100			Noradrenergic reuptake inhibition Controlled-release formulation available Maximum doses 700 mg day 1, then 600 mg/day IR; 500 mg/day ER Metabolized via CYP2D6, CYP2C19, CYP2C9 Caution with SSRIs Equianalgesic dosage not well studied
Partial agonist: buprenorphine	0.4	—		26–37	Partial mu agonist, weak kappa antagonist Available as once-weekly patch, single agent and in combination with naloxone formulations Metabolized via CYP3A4, UGT1A3 May precipitate withdrawal in patients receiving full mu agonists

Adverse Effects

Adverse effect	Specific agents
Constipation	Stool softeners Irritants Bulk laxatives Lubricants Enemas Peripheral mu antagonists ➢ Methylnaltrexone ➢ Naloxegol Lubiprostone
Nausea and vomiting	Promethazine Prochlorperazine Haloperidol Olanzapine 5-HT_3 antagonists Dronabinol Scopolamine

Nonpharmacological Management of Pain

Nonpharmacological methods are multimodal and are often used together with medications and other pain relieving methods. Some commonly used modalities are:

- **Physical therapy:** Specific exercise training helps to address fear avoidance and the severe deconditioning which is seen commonly in patients with chronic pain. Therapeutic exercise and stretching also serves to overcome long established fear avoidance behaviors.

- **Psychological therapy:**
    - *Cognitive behavior therapy (CBT)* is the best and most recommended of the psychological therapies for chronic pain management. CBT targets maladaptive behavioral responses to the pain, social and environmental factors.
    - *Mind-body techniques:* Several mindfulness techniques, structures exercise programs, deep relaxation techniques, Yoga and Tai Chi have been recommended for producing reduction in pain severity.
- **Acupuncture** has been used since several centuries for treatment of chronic pain and continues to be used. It has been recommended for use in chronic low back ache and chronic migraine.
- **Transcutaneous electrical nerve stimulation (TENS):** This is a surface applied neuromodulation system which is delivered by a trained physical therapist. It has been used in treatment of chronic pain despite lack of robust evidence of benefit.

END-OF-LIFE CARE

Q. IM13.18 Describe and discuss the ethical and the medicolegal issues involved in end- of -life care.

End-of-life care (EoLC) (is a subset of palliative care and refers to an approach to care whereby the focus is shifted towards comfort care, and away from curative intent therapies. During EoLC the patients may have <12 months to live and death is imminent. The focus of care is on comfort, dignity, good symptom control, quality of life and ***quality of dying.*** EoLC also includes bereavement support to the family for up to 13 months after the death.

The continuum of palliative care and end-of-life care in an illness trajectory is depicted in **Figure 14.14**.

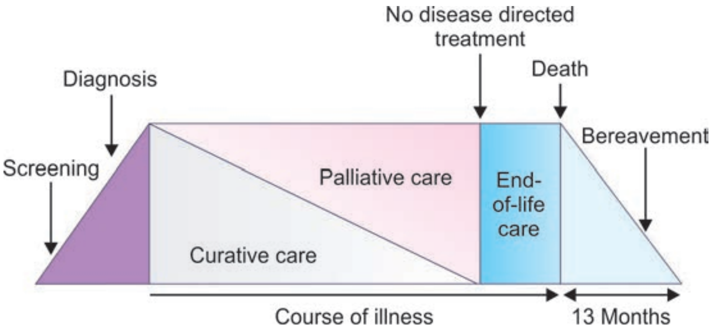

FIG. 14.14: Palliative Care Continuum as one-dimensional journey from screening and diagnosis to end-of-life care. Evidence is required to inform practice in all segments.

How to Identify that the Patient is Actively Dying?

The points given below are clinical aids to help the physician in ***recognizing the dying patient***. However, they are not definite clinical criteria and they may merely suggest poor prognosis and may not be indicative of a definite timeline for death. A patient who is sedated or on mechanical ventilation may not show any of these signs or symptoms.

The following clinical signs are usually present during the last 72 hours of a patient's life:

- Progressively falling blood pressure
- Tachycardia progressing to bradycardia and asystole
- Peripheral vasoconstriction—cold peripheries
- Altered breathing pattern (Cheynes—Stokes/irregular breathing)
- Change in skin color—duller/greyish blue/mottling—nails bluish
- Patient being increasingly bed bound/no spontaneous movements
- Patients stop verbalizing and have no response to questions
- Total detachment from surroundings/nil interest in food/water
- Bedridden patient with diminishing spontaneous movement
- Decreased passage of stools (Do not intervene unless there is significant discomfort from distension/impaction)
- Decreased urine output (Rule out bladder outlet obstruction)
- Comatose
- Severe cachexia
- Agitation/paranoia/terminal delirium

Clinical Features Indicative of <24 Hours Survival

- Loss of radial pulse
- Onset of jaw jerk with each breath

- Terminal delirium
- Terminal fever
- Death rattle

Symptom Management in EoLC

Symptom	Principles of management
Pain	➢ Route of drug administration may need to be changed ➢ Switch morphine PO to SC or SC infusion (or IV infusion)
Nausea and vomiting	➢ Use IV metoclopramide haloperidol or cyclizine
Terminal breathlessness	➢ Morphine/benzodiazepine and oxygen
Terminal agitation	➢ Haloperidol 10–30 mg/24 hr and/midazolam 10–60 mg/24 hr by continuous subcutaneous infusion
Care of skin and mucosa	➢ Positioning, care of pressure points ➢ Mouth care: Sponge tipped swabs can be used to moisten the mouth ➢ Eye care: Methylcellulose eye drops can be used
Death rattle	➢ Semiprone position to encourage postural drainage Pharmacological methods: Antisecretory drugs: ➢ Glycopyrronium ➢ Hyoscine hydrobromide ➢ Hyoscine butylbromide

CHAPTER
15

Nutrition

NUTRITIONAL ASSESSMENT

Q. IM23.1 Discuss and describe the methods of nutritional assessment in an adult and calculation of caloric requirements during illnesses.

Nutritional screening should include dynamic parameters rather than static ones, e.g., recent weight loss, current body mass index (BMI), recent food intake, and disease severity **(Table 15.1)**.

TABLE 15.1: Nutritional screening.

Indications for nutritional screening			
➢ If BMI of the patient <20.5 kg/m^2 ➢ Significant unintentional loss of weight in the past 3 months ➢ Decreased food intake in the past week ➢ Critically ill-patients			
Screening			
Nutritional status	*Score*	**Stress metabolism (severity of the disease)**	*Score*
None	0	*None*	0
Mild	1	*Mild stress metabolism*	1
Weight loss $>5\%$ in 3 months Or 50–75% of the normal food intake in the last week		Patient is mobile Increased protein requirement can be covered with oral nutrition *Hip fracture, chronic disease especially with complications, e.g., liver cirrhosis, chronic obstructive pulmonary disease (COPD), diabetes, cancer, chronic hemodialysis*	
Moderate	2	*Moderate stress metabolism*	2
Weight loss $>5\%$ in 2 months Or BMI 18.5–20.5 kg/m^2 and reduced general condition Or 25–50% of the normal food intake in the last week		Patient is bedridden due to illness Highly increased protein requirement may be covered with oral nutritional supplement (ONS) *Stroke, hematologic cancer, severe pneumonia, extended abdominal surgery*	
Severe	3	*Severe stress metabolism*	3
Weight loss $>5\%$ in 1 month Or BMI <18.5 kg/m^2 and reduced general condition Or 0–25% of the normal food intake in the last week		Patient is critically ill (intensive care unit) Very strongly increased protein requirement can only be achieved with (parenteral) enteral nutrition *APACHE-II >10, bone marrow transplantation, head traumas*	
Total (A)		Total (B)	
Age			
<70 years: 0 patient			
≥70 years: 1 patient			
TOTAL = (A) + (B) + Age			
≥3 points: Patient is at nutritional risk. Nutritional care plan should be set up *<3 points: Repeat screening weekly*			

Nutritional Anthropometry

- Body weight and BMI
- Skinfold measurements: Subcutaneous fat tissues (SFTs) normally account for half of the entire body fat mass, and the measurement of SFT gives information on the energy stores of the body, mainly fat stores (i.e., triglycerides). Biceps, triceps, subscapular, and suprailiac skin-fold thickness are measured.
- Mid-upper arm muscle circumference (MAMC) reflects the muscle mass, while the mid-arm muscle area (MAMA) gives information about the muscle protein stores, as half of the body's proteins are stored in the skeletal muscles. The MAMA is calculated from the MAMC and the triceps SFT [MAMA = MAMC – (0.314 × SFT)].
- Assessment of body composition: Body composition describes the body compartments, such as fat mass, fat-free mass, muscle mass, and bone mineral mass. The methods used are bioelectrical independence analysis, creatinine height index, dual energy X-ray absorptiometry, magnetic resonance imaging (MRI), computed tomography (CT), dilution method, and neutron activation.
- Laboratory investigations: Complete blood count, lipid profile, electrolytes, albumin, transferrin, prealbumin/transthyretin (TTR), retinol-binding protein (RBP), insulin-like growth factor-1 (IGF-1).

Signs and Symptoms of Micronutrient Deficiencies

Q. IM23.3 **Discuss and describe the etiology, causes, clinical manifestations, complications, diagnosis, and management of common vitamin deficiencies.**

Signs and symptoms of micronutrient deficiencies have been shown in **Table 15.2**.

TABLE 15.2: Signs and symptoms of micronutrient deficiencies.

Vitamin deficiency	*Manifestation*
	Fat-soluble vitamins
Vitamin A (Retinol)	Night blindness (nyctalopia), corneal xerosis, keratomalacia, xerophthalmia-Bitot's spots
Vitamin D (Ergocalciferol/ cholecalciferol)	➢ Rickets/osteomalacia ➢ Bone pain, costochondral beading ➢ Proximal myopathy
Vitamin E (Tocopherol)	Hemolysis, posterior column signs, ataxia, muscle wasting, retinitis pigmentosa-like changes, night blindness
Vitamin K (Phylloquinone and other menaquinones)	Dry bleeds (bruising, purpura) and wet bleeds (nose and GI bleeds)
	Water-soluble vitamin (B-complex and vitamin C)
B_1 (Thiamine)	➢ Wernicke/Korsakoff ➢ Beriberi ➢ Nystagmus ➢ Sixth cranial nerve palsy ➢ Ataxia ➢ Acidosis ➢ Dementia ➢ Paresthesia ➢ Neuropathy ➢ Cardiac failure ➢ Anemia
B_2 (Riboflavin)	➢ Ariboflavinosis ➢ Angular stomatitis, glossitis, magenta tongue
B_3 (Niacin)	Pellagra dermatitis of sun-exposed areas, dementia, poor appetite, difficulty sleeping, confusion, mouth sore
B_4 (Adenine)*	➢ Immune dysfunction ➢ Aging
B_5 (Pantothenic acid)	Nausea, abdominal pain, paresthesia, burning feet
B_6 (Pyridoxine)	Poor appetite, lassitude, oxaluria
B_7 (Biotin)	Dermatitis, depression, lassitude, muscle pains, electrocardiogram abnormalities, blepharitis
B_8 (Inositol)*	Depression and other psychiatric manifestations
B_9 (Folic acid)	Macrocytic anemia, thrombocytopenia and megaloblastic bone marrow
B_{10} (PABA)*	➢ Free radical damage ➢ Sun burns and skin rashes
B_{11} (Salicylic acid)*	Works in tandem with vitamin B_{12}
B_{12} (Cobalamin)	Subacute combined degeneration, macrocytic anemia, icterus, knuckle pigmentation

Contd...

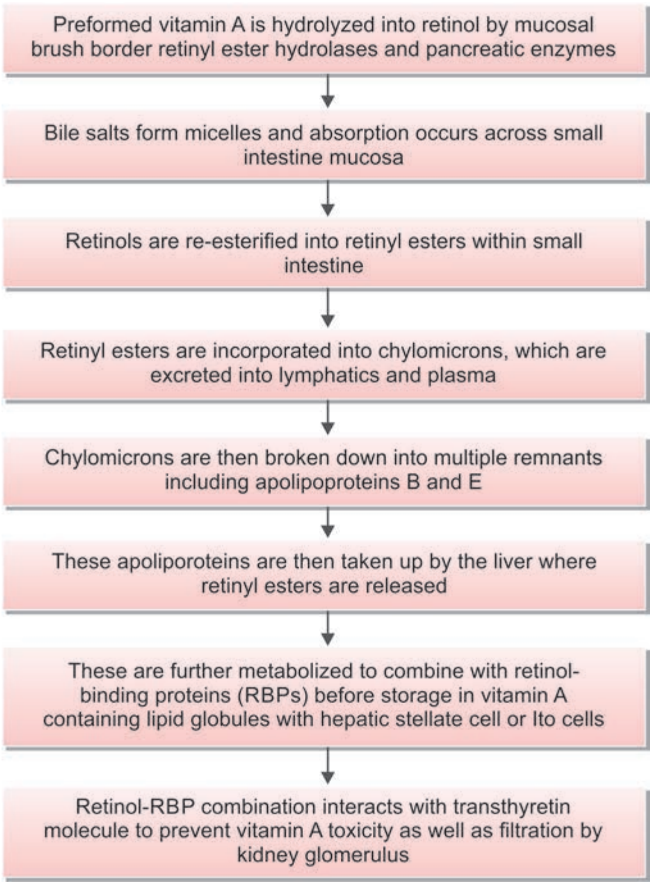
Contd...

Vitamin deficiency	***Manifestation***
Vitamin C (Ascorbic acid)	➢ Scurvy ➢ Poor wound healing, fatigue, limb pain, scorbutic rosary, difficulty sleeping, gingivitis, perifollicular purpura, hyperkeratosis
*** Note:** Vitamin B$_4$, B$_8$, B$_{10}$, and B$_{11}$ are no longer labeled as vitamins, as they do not fit the official definition of vitamin.	
Minerals	
Iron	➢ Koilonychia ➢ Smooth tongue ➢ Anemia ➢ Esophageal web
Copper	Microcytic hypochromic anemia, neutropenia, scurvy-like bone lesions, osteoporosis
Zinc	➢ Acrodermatitis enteropathica ➢ Peristomal/perinasal/perineal ➢ Erythema, thin hair, diarrhea, apathy, anorexia, growth failure, hypoglycemia ➢ Distorted or diminished taste (hypogeusia)
Chromium	Peripheral neuropathy, hyperglycemia
Selenium	Cardiomyopathy
Iodine	Goiter
Others	
Protein deficiency	➢ Pitting edema ➢ Hair: Thinning, easily pluckable with dyspigmentation or flag sign, and change in texture to silken, sparse hair ➢ Dermatosis with desquamation of the so-called flaky-paint type, with or without hyperpigmentation

VITAMIN A

Q. IM23.3 Discuss and describe the etiology, causes, clinical manifestations, complications, diagnosis and management of vitamin A deficiency.

- Vitamin A is the name given to a group of fat-soluble vitamins and includes **provitamin A carotenoids** and **preformed vitamin A.**
  - Provitamin A carotenoids—found in plants. For example, beta-carotene, alpha-carotene, and beta-cryptoxanthin. Sources—dark green and deeply colored fruits and vegetables.
  - Preformed vitamin A (retinol, retinal, retinoic acid, and retinyl esters) is the most active form of vitamin A; it is mostly found in animal sources of food and is also the form supplied by most supplements. Sources—liver, fish, milk, eggs, butter, cheese.
- **Vitamin A metabolism (Flowchart 15.1):**
  - Provitamin A (from plant sources) is cleaved to retinal before absorption. This step is subject to feedback regulation. Therefore, excessive intake of vitamin A from plant sources rarely causes toxicity.
  - Preformed vitamin A (from animal sources/ supplements): This step is highly efficient and is not subject to feedback regulation. Therefore, excessive intake of vitamin A from animal sources can cause toxicity.
  - About 50–85% of total body retinol is stored in the liver.
- **Functions of vitamin A:** Vitamin A has several metabolic roles. The main functions of vitamin A in humans are as follows:
  - **Maintenance of normal vision:** Vitamin A is essential for **dark adaptation** and its deficiency causes nyctalopia. Mainly controlled by retinaldehyde.



FLOWCHART 15.1: Vitamin A metabolism.
Preformed vitamin A is hydrolyzed into retinol by mucosal brush border retinyl ester hydrolases and pancreatic enzymes
Bile salts form micelles and absorption occurs across small intestine mucosa
Retinols are re-esterified into retinyl esters within small intestine
Retinyl esters are incorporated into chylomicrons, which are excreted into lymphatics and plasma
Chylomicrons are then broken down into multiple remnants including apolipoproteins B and E
These apoliporoteins are then taken up by the liver where retinyl esters are released
These are further metabolized to combine with retinol-binding proteins (RBPs) before storage in vitamin A containing lipid globules with hepatic stellate cell or Ito cells
Retinol-RBP combination interacts with transthyretin molecule to prevent vitamin A toxicity as well as filtration by kidney glomerulus

- **Host resistance to infections:** Vitamin A deficiency causes keratinization of mucous membranes and thereby increases the risk of infections. RBP is a **negative "acute phase protein"**.
- **Immune function:** Vitamin A has the ability to stimulate the immune system. Retinoids are required for normal growth, fetal development, fertility, hematopoiesis, and immune function.
- **Control of cell growth and differentiation:** Vitamin A is needed for the maintenance of the surface linings of the eyes, growth and repair of epithelial cells, and integrity of the epithelial cells of the respiratory, urinary, and intestinal tracts. In vitamin A deficiency, mucus-secreting cells are replaced by keratin-producing cells and this process is known as squamous metaplasia.
- **Regulation of lipid metabolism:** Fatty acid metabolism, including fatty acid oxidation in fat tissue and muscle, adipogenesis, and lipoprotein metabolism require vitamin A.
- **Antioxidant:** Retinoids, beta-carotene, and some related carotenoids act as photoprotective and act as antioxidants.
- **Other functions:** Vitamin A is involved in growth of bone, reproduction, embryonic development, and the regulation of adult genes.
- **Tretinoin**, i.e., all-trans retinoic acid (ATRA) is also used to treat acute promyelocytic leukemia (APL), **isotretinoin** is used to treat psoriasis and 13-cis-retinoic acid is used in the treatment of acne.

TABLE 15.3: Causes of vitamin A deficiency.

Primary causes	*Secondary causes*
➢ Prolonged dietary deprivation	➢ Sprue
➢ Vegetarians	➢ Cystic fibrosis
➢ Refugees	➢ Pancreatic insufficiency
➢ Chronic alcoholics	➢ Duodenal bypass
➢ Toddlers	➢ Chronic diarrhea
➢ Preschool children	➢ Bile duct obstruction
	➢ Giardiasis and cirrhosis

Vitamin A Deficiency (Table 15.3)

Clinical Features/Manifestations

- **Vision**
  - Xerophthalmia describes a spectrum of eye disease caused by vitamin A deficiency, which includes Bitot's spots, corneal xerosis and keratomalacia.
    - Bitot's spots **(Fig. 15.1)**: In young children with vitamin A deficiency, areas of abnormal squamous cell proliferation and keratinization of the conjunctiva known as Bitot's spots can be seen.
    - Corneal xerosis refers to dryness of cornea.
    - Keratomalacia: In advanced disease, the cornea becomes hazy and erosions can develop, finally leading to its destruction (keratomalacia).
  - Night blindness (nyctalopia) and retinopathy.
- **Nonspecific skin changes**
  - Xerosis of skin in vitamin A deficiency has been shown in **Figure 15.2**.
  - Hyperkeratosis
  - Phrynoderma (follicular hyperkeratosis)
- **Impairment of humoral and cell-mediated immunity** causing increased susceptibility to infections.
- **Other features:**
  - Fatigue
  - Anemia
  - Diarrhea
  - Decreased growth rate
  - Decreased bone development
  - Infertility.

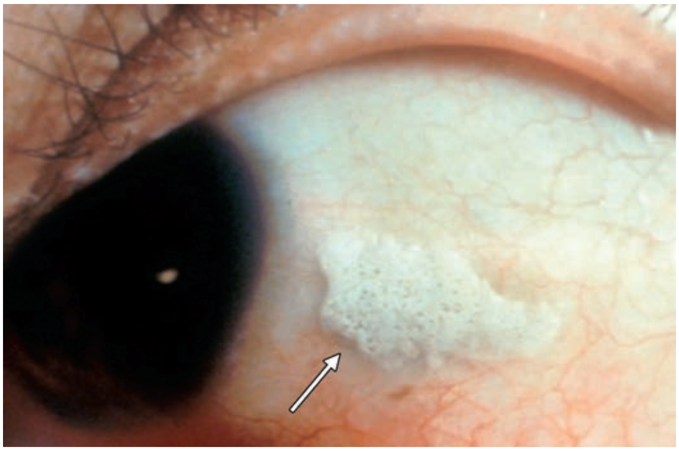


FIG. 15.1: Bitot's spot.

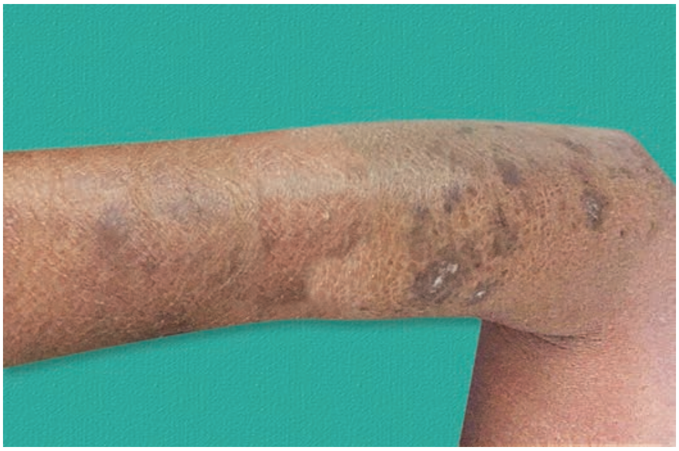

FIG. 15.2: Xerosis of skin in vitamin A deficiency.

Laboratory Investigations

- **Serum retinol level:** Normal range is 28–86 µg/dL (1–3 µmol/L). The level decreases in vitamin A deficiency.

- **Albumin levels** are indirect measures of vitamin A levels.
- **Complete blood count** (CBC) with differential count to be done, if there is a possibility of anemia, infection, or sepsis.

Diagnosis

- It is mainly on the basis of the **clinical features**. Response to replacement therapy is the best way for the diagnosis.
- Serum retinol levels <20 mg/dL suggest deficiency, or the ratio of retinol: RBP <0.8 suggests deficiency.

For populations in which vitamin A deficiency is endemic, the WHO recommends the following replacement approaches:

Universal periodic distribution: Periodic supplementation is recommended for populations endemic for vitamin A deficiency, at the following doses (where 1 microgram retinol = 3.3 international units).

- Infants 6 to 12 months of age: 100,000 international units orally (30 mg retinol equivalent)—one dose
- Children 12 to 59 months of age: 200,000 international units orally (60 mg retinol equivalent)—dose repeated every four to six months.
- Pregnant females living in endemic areas of vitamin A deficiency should receive vitamin A supplementation to prevent night blindness; supplements should be provided as frequent small doses not exceeding 10,000 IU/day or 25,000 IU/week minimum of 12 weeks during pregnancy until delivery. Replacement should be avoided in the first 60 days of gestation in view of possible teratogenicity.

Targeted supplementation for disease and xerophthalmia: Vitamin A is given in 3 doses at the age-specific doses.

1. Infants <6 months of age: 50,000 international units orally
2. Infants 6 to 12 months of age: 100,000 international units orally
3. Children >12 months: 200,000 international units orally

The first dose is given immediately upon diagnosis, the second on the following day, and the third dose at least two weeks later.

Therapeutic uses of Vitamin A

- Measles
- Dermatology—retinoic acid has been used for many hyperkeratotic and hyperproliferative disorders of skin
- Atherosclerosis—because carotenoids are antioxidants, they were investigated for possible prevention of cardiovascular disease. However not recommended.
- Acute promyelocytic leukemia—all-trans retinoic acid (ATRA, or tretinoin) is a synthetic oxidative metabolite of retinoic acid and has been used in acute promyelocytic leukemia.

Vitamin A Toxicity

Q. Write short essay/note on hypervitaminosis A and its signs.

- **Types of toxicity:** Vitamin A toxicity can be **acute—**acute toxicity occurs in adults when a single dose of >660,000 international units (>200,000 micrograms) of vitamin A is ingested or **chronic—**chronic toxicity occurs with long-term ingestion of vitamin A doses in amounts higher than 10 times the RDA [i.e., toxicity may occur with chronic ingestion of approximately 33,000 international units (10,000 micrograms) of retinol in adults].
- Both types of toxicity cause **headache and increased intracranial pressure (pseudotumor cerebri).**
  - **Acute** toxicity also produces nausea and vomiting, vertigo, diplopia, bulging fontanels, seizures, exfoliative dermatitis.
  - **Chronic** toxicity causes changes in skin, hair (loss), and nails; liver and bone damage; double vision, ataxia, hyperlipidemia and vomiting.
- **Retinol is teratogenic** and incidence of birth defects in infants is high with vitamin A intakes of >3 mg a day during pregnancy (**spontaneous abortions** and **fetal malformations**, including microcephaly and cardiac anomalies).
- **Diagnosis is usually clinical**.
- Unless birth defects are present, adjusting the dose almost always leads to complete recovery. Recommended dietary allowances (RDAs)/adequate intake of fat-soluble vitamins for individuals **(Table 15.4A)**.

TABLE 15.4A: Recommended dietary allowances (RDAs)/adequate intake of fat-soluble vitamins for different age group.

Age group	*Vitamin A (RAE*)*	*Vitamin D (μg/d)*	*Vitamin E (μg/d)*	*Vitamin K (μg/d)*
Infants	400–500	5	4–5	2–2.5
Children (1–13 yr)	300–600		6–11	30–60
>14 years				
➢ Males	900	5–15	15	75–120
➢ Females	600–700		11–15	75–90
Pregnancy	750–770	5	15	
Lactation	1200–1300		19	

*1 RAE (retinol activity equivalents) = 1 μg retinol, 12 μg β-carotene; 1 μg calciferol = 40 IU vitamin D.

TABLE 15.4B: Dietary reference intake (DRI) for water-soluble vitamins.

31–50 years	1.4	ND	1.6	ND	17	35	7	ND	2	100	35	ND	120	2,000

Dietary reference intakes (DRIs) include the following measures describing optimal nutrient intake:
Recommended dietary allowance (RDA): The level of dietary intake that is sufficient to meet the daily nutrient requirements of 97% of the individuals in a specific life stage group.
Adequate intake (AI): An approximation of the average nutrient intake that sustains a defined nutritional state, based on observed or experimentally determined values in a defined population.
Upper tolerable level (UL): The maximum level of daily nutrient intake that is likely to pose no risk of adverse health effects in almost all individuals in the specified life stage or gender group.
RDAs and AIs may both be used as goals for individual intake. The AI is used when there are insufficient data to determine the RDA for a given nutrient.

- **Carotenemia** is common among infants and toddlers who eat large amounts of carrots and green leafy vegetables. It can be confused with jaundice, but discoloration of skin spontaneously resolves once the intake of carotenoid rich food is reduced.

Dietary reference intake for water-soluble vitamins has been shown in **Table 15.4B**.

VITAMIN B COMPLEX

Thiamine (B_1)

Q. IM23.3 Discuss and describe the etiology, causes, clinical manifestations, complications, diagnosis and management of vitamin B_1 deficiency.

- **Functions:** Thiamine is an important **water-soluble** vitamin.
  - Involved in **carbohydrate, fat, amino acid, glucose, and alcohol metabolism**.
  - Vitamin B_1 is **essential** for the **coenzyme**, thiamine pyrophosphate (TPP). It is required for the following reactions:

  - Decarboxylation of pyruvate (glycolytic pathway) to acetyl CoA (Krebs cycle)
    - Transketolase in the hexose monophosphate (HMP/pentose) shunt pathway
    - Decarboxylation of alpha-ketoglutarate to succinate (Krebs cycle).
  - Has an additional role in neuronal conduction.
- **Sources:** These vitamins can be produced by plants and some microorganisms. However, animals cannot synthesize them. In humans, the source is diet, though small amounts may be synthesized by intestinal bacteria.
- **Dietary sources:** Good dietary sources of thiamine are **whole wheat flour, unpolished rice, cereals, grains, beans, nuts and yeast**. There is little or no thiamine in milled rice and grains. Thus, thiamine deficiency is more common in individuals who consume mainly a rice-based diet.
- It is also present in **liver, meat, and eggs**.
- **Requirement:** Up to 30 mg of thiamine can be stored in body tissues. Required daily allowance (RDA) is **0.5–0.9 mg daily for children, 1.2 mg daily for adult men, and 1.1 mg daily for nonpregnant adult women**.
- Requirement increases with increased carbohydrate intake, pregnancy and lactation, smoking, alcoholism, prolonged antibiotic intake, serious or prolonged illness.
- It causes of thiamine deficiency are listed in **Box 15.1** and clinical syndromes of thiamine deficiency are mentioned in **Box 15.2**.

Box 15.1: Causes of thiamine deficiency.

Lack of thiamine intake
- Starvation state
- Food items like milled rice, raw freshwater fish, raw shellfish, and ferns that have a high level of *thiaminase*
- Food high in *anti-thiamine factor,* such as tea, coffee, and betel nuts
- Alcoholic state

Increased consumption states
- Diets high in carbohydrate or saturated fat intake
- Pregnancy and lactation
- Hyperthyroidism
- Fever—severe infection
- Increased physical exercise

Decreased absorption
- Chronic intestinal disease
- Alcoholism
- Malnutrition
- Gastric bypass surgery
- Malabsorption syndrome—celiac and tropical sprue

Increased depletion
- Diarrhea
- Peritoneal dialysis, hemodialysis, diuretic therapies
- Hyperemesis gravidarum

Consequences of Thiamine Deficiency

- Consequence of thiamine deficiency is **impaired glucose oxidation.**
- Cells **cannot metabolize glucose** aerobically to generate energy as ATP.
- **Neuronal cells** are **most susceptible**, because they depend almost exclusively on glucose for energy requirements.
- Causes an **accumulation of pyruvic and lactic acids**. This in turn produces **vasodilatation** and **increased cardiac output.**

Beriberi (Box 15.2)

Q. Write short essay/note on clinical features of beriberi/vitamin B_1 (thiamine) deficiency.

1. **Wet (cardiovascular) beriberi:** Wet beriberi is the term used for the **cardiovascular involvement** of thiamine deficiency.
   - First effects are **vasodilatation, tachycardia**, a wide pulse pressure, sweating, warm skin, and lactic acidosis.
   - Later, **congestive heart failure** develops, causing orthopnea, and pulmonary and peripheral edema. Marked cardiomegaly is present.
   - **Infantile beriberi** occurs in infants (usually by age 3–4 weeks) who are breastfed by **thiamine-deficient mothers.** Heart failure can develop suddenly and presents with edema, aphonia, tachycardia, tachypnea, and absent deep tendon reflexes. If prompt treatment is not given, death occurs quickly.
     - **Shoshin beriberi:** A more rapid form of wet beriberi is termed **acute fulminant cardiovascular beriberi.**
2. **Dry beriberi:** Dry beriberi usually manifests insidiously with **symmetrical peripheral neuropathy.**
   - **Early symptoms***:* There is bilateral and roughly symmetrical heaviness and stiffness of the legs.
   - **Later symptoms***:* These include weakness, numbness, and pins and needles (occurring in a stocking-glove distribution).

Box 15.2: Clinical syndromes of thiamine deficiency.

- Wet beriberi—high cardiac output failure
- Dry beriberi—peripheral neuropathy
- Wernicke's encephalopathy
- Korsakoff's psychosis
- Leigh syndrome (progressive subacute necrotizing encephalomyopathy)

- **Distribution of neuropathy:** They affect predominantly the lower limbs. They begin with paresthesias in the toes, burning in the feet (severe at night), muscle cramps in the calves, pains in the legs, and plantar dysesthesias.
- **Physical signs**: Calf muscle tenderness, difficulty rising from a squatting position, and decreased vibratory sensation in the toes. The ankle jerk reflexes are lost.
- Deficiency may also cause **degeneration of thalamus, mammillary bodies, and cerebellum**.

Biochemical tests

- Measurement of thiamine, pyruvate, and lactate levels in blood or urine.
- Erythrocyte thiamine transketolase activity.

Q. Write short essay/note on management/treatment of beriberi/vitamin B_1 (thiamine) deficiency.

Management

- Complete bed rest.
- Treatment for beriberi in adults typically starts with parenteral administration of thiamine if the patient is critically ill (e.g., 100 to 200 mg three times daily for two to three days), followed by oral thiamine, 5 to 30 mg/day
- Parenteral thiamine produces marked diuresis (in wet beriberi), resulting in dramatic improvement in the symptoms.

Q. Write short essay/note on Wernicke's encephalopathy.

3. **Wernicke's encephalopathy:** It is an acute neuropsychiatric condition. Initially, it is reversible biochemical brain lesion caused by depletion of vitamin B_1 (thiamine). Its causes are listed in **Box 15.1.**

   Clinical features:

   - Wernicke's encephalopathy (WE) is a **triad of global confusion, ophthalmoplegia, and ataxia**, along with confusion. Impairment in the synthesis of one of the important enzymes of the **pentose phosphate pathway (erythrocyte transketolase)** may explain such a predisposition.
   - **Encephalopathy:** It is characterized by confusion, severe disorientation, indifference, and inattentiveness. There is also impaired memory and learning. If untreated patients will progress through stupor and coma to death.
   - **Oculomotor dysfunction:** Nystagmus, lateral rectus palsy, and lesions of the oculomotor, abducens, and vestibular nuclei resulting in conjugate gaze palsy.
   - **Gait ataxia:** Ataxia mainly involves stance and gait. It is probably due to a combination of polyneuropathy, cerebellar involvement, and vestibular dysfunction.

   Diagnosis: For confirmation of the diagnosis, measure the circulating thiamine concentration or transketolase activity in red cells using fresh heparinized blood. MRI may show **periventricular lesions** surrounding third ventricle, aqueduct and fourth ventricle with **petechial hemorrhages** in acute cases and atrophy of mammillary bodies in chronic cases.

Management

- Wernicke's disease is a medical emergency and requires immediate administration of thiamine.
- **Dosage:** 500 mg of thiamine intravenously, infused over 30 minutes, 3 times daily for 2 consecutive days and 250 mg intravenously or intramuscularly once daily for an additional 5 days, in combination with other B vitamins.
- Magnesium is often needed because it is a cofactor required for normal functioning of thiamine-dependent enzymes.
- Wernicke's encephalopathy may be precipitated by administration of intravenous glucose solutions to individuals with thiamine deficiency. In susceptible individuals, glucose administration should be preceded or accompanied by thiamine 100 mg IV.

4. **Korsakoff's psychosis/syndrome**

Q. Write a short note on Korsakoff's psychosis/syndrome.

- Korsakoff's psychosis is caused by **deficiency of thiamine** with **involvement of central nervous system.**
- **Memory disturbances:** It is predominantly associated with **defect in retentive memory** (severe defect in storing new information and learning). Thus, there are **disturbances of short-term memory.** There are also marked deficits in anterograde and retrograde memory.
- Other features include apathy, an intact sensorium and relative preservation of long-term memory and other cognitive skills.
- **Confabulation:** It is a memory disturbance, characterized by the production of fabricated, distorted or misinterpreted memories about oneself or the world, without the conscious intention to deceive. Attention and social behavior are relatively maintained. Affected individuals can perform conversation that may seem normal to an unsuspecting spectator.

- The syndrome is common in **chronic alcoholics**. It may also be seen with thiamine deficiency due to **gastric disorders** (e.g., carcinoma, chronic gastritis, or persistent vomiting).

Treatment: Parenteral thiamine (100 mg IM daily for 7 days).

Thiamine Metabolism Dysfunction Syndromes

- **Thiamine-responsive megaloblastic anemia**
  - Mutations in the *SLC19A2* gene (encodes thiamine transporter)
  - Syndrome of megaloblastic anemia, diabetes mellitus, and sensorineural deafness
  - Affects infants and adolescents.
- **Thiamine metabolism dysfunction syndrome type 2**
  - Mutations in the *SLC19A3* gene (encodes thiamine transporter)
  - Causes episodic encephalopathy
  - May be precipitated by a febrile episode.

Vitamin B_2 (Riboflavin)

Q. IM23.3 Discuss and describe the etiology, causes, clinical manifestations, complications, diagnosis and management of vitamin B_2 deficiency.

- **Source:** Milk and eggs, meats, fish, green vegetables, yeast, and enriched foods (fortified cereals and breads).
- **Actions:**
  - Essential component of co-enzymes involved in multiple cellular metabolic pathways like tricarboxylic acid (TCA) cycle and beta-oxidation of fatty acids.
  - Flavoproteins are involved in multiple redox reactions and function as electron transporters.

Deficiency

- **Diagnosis:**
  - **Erythrocyte glutathione reductase assay**—coefficient >1.4 indicates riboflavin deficiency.
  - Plasma, RBC or urine **riboflavin concentrations**.
- **Causes:**
  - Anorexia nervosa
  - Malabsorptive syndromes
  - Glutaric acidemia type 1
  - Multiple acyl-coenzyme A (CoA) dehydrogenase deficiency (MADD)
  - Brown-Vialetto-Van Laere syndrome (defect in riboflavin transporter)
  - Long-term use of barbiturates—can cause oxidation of riboflavin.
  - Lactose intolerance—because dairy products are a good source of riboflavin.
- **Features** of riboflavin deficiency include:
  - Cheilitis
  - Stomatitis
  - Glossitis
  - Normochromic anemia
  - Seborrheic dermatitis
- Pure deficiency of riboflavin is rare.
- **Therapeutic uses:**
  - Multiple CoA dehydrogenase deficiency
  - Lactic acidosis due to zidovudine/stavudine—responds to riboflavin
- **RDA:**
  - 1.3 mg daily for adult men
  - 1.1 mg daily for nonpregnant adult women

Vitamin B_3 (Niacin)

- **Sources:**
  - Yeast, meats (especially liver), grains, legumes, corn used in tortilla, and seeds.
  - Tryptophan can be converted to a niacin derivative in the liver. However, it requires approximately 60 mg of tryptophan to produce 1 mg of niacin, and this process requires vitamin B_6 (pyridoxine).

- **Actions:** NAD/NADP are co-factors for many enzymatic redox reactions.
- **RDA:** Dosed as a "niacin equivalent" (NE), in which 1 NE is equal to 1 mg of niacin, or 60 mg of dietary tryptophan. RDA is 16 mg for adult males, and 14 mg daily for nonpregnant adult females.

Pellagra

Q. IM23.3 Discuss and describe the etiology, causes, clinical manifestations, complications, diagnosis and management of niacin deficiency.

- **Vitamin B_3 niacin (nicotinamide) deficiency** causes a metabolic encephalopathy called **pellagra**. Causes of pellagra are listed in **Box 15.3**.
- It is found mostly in populations in which corn is the major source of energy in parts of China, Africa, and India. Pellagra means raw skin.

Box 15.3: Causes of pellagra.

- **Inadequate intake:** Maize or jowar (sorghum) diet, malnutrition, chronic alcoholism (who eat little), anorexia nervosa
- Generalized **malabsorption** (rare).
- **Drug-induced:**
  - Prolonged isoniazid therapy
  - Pyrazinamide
  - 6-mercaptopurine
  - 5-flouuracil
  - Azathioprine
  - Ethionamide
  - Carbamazepine
  - Phenytoin
  - Phenobarbitone.
- **Other disorders:**
  - **Hartnup's disease:** It is a rare genetic disorder, in which there is reduced absorption of basic amino acids including tryptophan by the gut.
  - **Carcinoid syndrome** and pheochromocytoma: In these conditions, tryptophan metabolism is diverted away from the formation of nicotinamide to form amine-producing pellagra-like symptoms.

Clinical Features

Pellagra has been easily remembered a disease of four **D**s namely: (1) **dermatitis;** (2) **diarrhea;** (3) **dementia (depression);** and (4) **death**. However, these features are not always observed and the mental changes are not a true dementia.

- **Skin manifestations:**
  - **Casal's necklace or collar rash:** Characteristic skin rash develops that is hyperpigmented and scaling that develops in skin areas exposed to sunlight. This rash forms a ring around the neck and is termed Casal's necklace **(Fig. 15.3)**.
  - **Dermatitis:** Lesions of the skin may progress to vesiculation, cracking (ulceration), exudation, and secondary infection. Symmetrical chronic thickening, dryness and pigmentation may be seen on the dorsal surfaces of the hands.
- **Gastrointestinal (GI) tract:**
  - **Diarrhea:** It may be in part due to proctitis and in part due to malabsorption. It is often a feature accompanied by anorexia, nausea, glossitis, and dysphagia indicating noninfective inflammation of the entire GI tract.
  - Other features include raw, painful, bright red tongue (glossitis), angular stomatitis, vaginitis, esophagitis, vertigo, and burning dysesthesias.

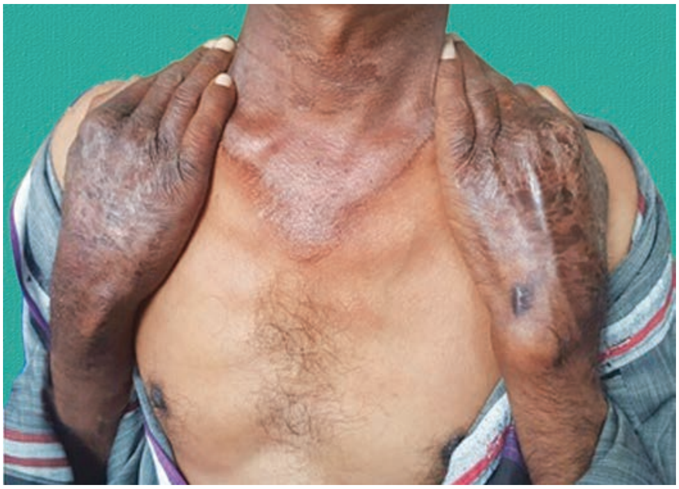

FIG. 15.3: Casal's necklace and dermatitis.

- **Dementia:**
  - This occurs in chronic severe deficiency and may also develop hallucinations and acute psychosis.
  - Milder deficiency may present with depression, apathy and sometimes thought disorders.
  - Other neurologic symptoms include insomnia, anxiety, disorientation, tremor, delusions, dementia, and encephalopathy.

Diagnosis

- Diagnosis in **endemic region** depends on the clinical features. Other vitamin deficiencies can also produce similar changes (e.g., angular stomatitis).
- **Dramatic improvement:** The response is usually rapid in the skin (within 24 hours), diarrhea and a striking improvement occurs in the patient's mental state **with nicotinamide** treatment.
- Niacin status can be assessed by measuring urinary N-methylnicotinamide, 2-pyridonenicotinamide or by measuring the erythrocyte NAD:NADP (ratio).

Management/Treatment

- **Nicotinamide:** 100–200 mg 3 times daily orally (approximately 300 mg daily) with a maintenance dose of 50 mg daily.
- **High-protein diet** with **adequate nutrients** and treatment of malnutrition.
- **Supplementation of other vitamin B** complex with **iron and folic acid** is also given, as other deficiencies are often likely to be present.
- In moderate-to-high doses (1–3 g/day), niacin is a well-established antihyperlipidemic agent.

Vitamin B_{12} and Folic Acid

Discussed in Chapter 9.

Vitamin B_5 (Pantothenic Acid)

- **Sources:**
  - Egg yolk, liver, kidney, broccoli, and milk
  - Pantothenic acid is also produced by **bacteria in the colon**
  - Main dietary source of pantothenic acid is in the form of **coenzyme A**.
- **Actions:** CoA is involved in **metabolism** of vitamins A, D, cholesterol, steroids, heme A, fatty acids, carbohydrates, amino acids, and proteins.
- **RDA:**
  - The recommended intake for pantothenic acid is expressed as **adequate intake (AI)** rather than recommended dietary allowance (RDA).
  - The AI is 2–4 mg daily for children and 5 mg daily for adult men and women.
- **Deficiency:** Pantothenic acid deficiency is very rare in humans.
- **Clinical manifestations:**
  - Paresthesias and dysesthesias, referred to as "**burning feet syndrome**"
  - Gastrointestinal disturbance, depression, muscle cramps, hypoglycemia, ataxia, etc.
- **Diagnosis:**
  - Blood, plasma, serum or urine pantothenic acid levels
  - **Urine levels** are most reliable indicator of dietary intake.

Management/Treatment: Oral pantothenic acid (vitamin B_5)—5 mg/day.

Vitamin B_6 (Pyridoxine)

Q. IM23.3 Discuss and describe the etiology, causes, clinical manifestations, complications, diagnosis and management of vitamin B_6 deficiency.

Vitamin B_6 consists of **pyridoxine, pyridoxamine, pyridoxal**, and the **phosphorylated derivatives** of each of these compounds.

- **Sources:**
  - Pyridoxine and pyridoxamine are predominantly found in plant foods.
  - Pyridoxal is most commonly derived from animal foods.
  - Meats, whole grains, vegetables, and nuts are the best sources.
- **Actions:**
  - Gluconeogenesis
  - Decarboxylation of amino acids
  - Conversion of tryptophan to niacin
  - Heme synthesis
  - Sphingolipid biosynthesis
  - Neurotransmitter synthesis
  - Steroid hormone modulation
  - Trans-sulfuration pathway by which homocysteine is converted into cystathionine and its subsequent conversion to cysteine.
- **RDA:**
  - 1.3 mg daily for young men and women
  - 1.7 mg daily for men older than 50 years
  - 1.5 mg daily for women older than 50 years

Deficiency

- Overt deficiency is rare.
- **Causes:**
  - **Drugs—**isoniazid, penicillamine, hydralazine, and levodopa/carbidopa
  - Associated with—asthma, diabetes, alcoholism, heart disease, pregnancy, breast cancer, Hodgkin's lymphoma, and sickle-cell anemia
- **Clinical manifestations:**
  - Nonspecific stomatitis, glossitis, cheilosis, irritability, confusion, and depression, and possibly peripheral neuropathy.
  - Severe deficiency is associated with **seborrheic dermatitis, microcytic anemia,** and **seizures**
  - A number of genetic syndromes affecting pyridoxal phosphate (PLP) dependent enzymes such as homocystinuria, cystathioninuria, and xanthurenic aciduria mimic vitamin B_6 deficiency.
  - An inborn error of pyridoxine metabolism is responsible for **pyridoxine-dependent epilepsy.**
  - Cystathionine synthase is a PLP-dependent enzyme, which produces cystathionine from serine and homocysteine. As a result, vitamin B_6 insufficiency can lead to elevations in plasma homocysteine concentrations, a risk factor for the development of atherosclerosis and venous thromboembolism.
- **Diagnosis:**
  - **PLP concentrations** >30 nmol/L (>7.4 ng/mL) are normal.
  - **Erythrocyte transaminase activity**, with and without PLP added.
  - Urinary 4-pyridoxic acid excretion >3.0 mmol/day
  - Urinary excretion of xanthurenic acid is normally <65 mmol/day following a 2 g tryptophan load**. Increased xanthurenic acid excretion** suggests vitamin B_6 deficiency due to abnormal tryptophan metabolism.
- **Toxicity:** Peripheral neuropathy, dermatoses, photosensitivity, dizziness, and nausea have been reported with pyridoxine of over 250 mg/day.

Treatment:
- 50 mg/day in regular deficiency
- In case of deficiency secondary to certain drugs—higher doses of 100–200 mg/day are given.

Biotin

- **Sources:** Liver, egg yolk, soybean products, and yeast
- **Actions: Essential cofactor** for several carboxylase enzyme complexes involved in carbohydrate, amino acid, and lipid **metabolism**.
- **RDA:** The AI is 8–12 mg daily for children and 30 mg daily for adults.

Deficiency

- Deficiency is rare.
- **Causes:**
  - Long-term **parenteral nutrition**
  - Consumption of **large amounts of raw egg whites** (which contain avidin, a substance that binds to biotin and prevents its absorption), can also lead to biotin deficiency.
  - Secondary biotin deficiency can occur due to **lack of a specific enzyme** (**biotinidase**), which is required for release of protein-bound biotin to make it bioavailable.
- **Clinical manifestations:**
  - **Dermatitis** around the eyes, nose and mouth, conjunctivitis, alopecia
  - **Neurologic symptoms**, including changes in mental status, lethargy, hallucinations, and paresthesias
  - Myalgia, anorexia, and nausea
  - Multiple carboxylase deficiency—inherited defects of biotin metabolism
  - The **infantile form** is caused by a **deficiency of holocarboxylase synthetase** and presents in the first week of life with lethargy, poor muscle tone, and vomiting.
  - A **later-onset form** is caused by **biotinidase deficiency** and is associated with a slow but progressive loss of biotin in the urine, leading to organic aciduria; it is characterized by ataxia, ketoacidosis, dermatitis, seizures, myoclonus, and nystagmus.

- **Diagnosis:**
  - **Decreased urine biotin** concentrations.
  - Increased urinary excretion of 3-hydroxyisovaleric acid after leucine challenge.
  - Decreased activity of biotin-dependent enzymes in lymphocytes.

Treatment: Biotin in the dose of 10 mg/day.

VITAMIN C

Q. IM23.3 Discuss and describe the etiology, causes, clinical manifestations, complications, diagnosis and management of vitamin C deficiency.

- Vitamin C (ascorbic acid) is a **water-soluble** vitamin.
- **Sources:**
  - Citrus fruits, tomatoes, potatoes, brussel sprouts, cauliflower, broccoli, strawberries, cabbage, and spinach
  - Breast milk provides an adequate source of ascorbic acid for newborns and infants.
- **Metabolism:**
  - Ascorbic acid is absorbed in the **distal small intestine**.
  - Usual dietary doses of up to 100 mg/day are almost completely absorbed. As dietary concentrations increase, a smaller fraction is absorbed.
  - Pharmacologic dosing (>1,000 mg/day) can result in absorption rates of <50%
  - **Blood concentrations** of ascorbic acid are **regulated by renal excretion**. Excess amounts are filtered by renal glomeruli and reabsorbed via the tubules to a predetermined threshold.
  - **Dehydroascorbic acid** is the preferred form for **erythrocytes and leukocytes.**
  - The greatest concentrations of ascorbic acid are found in the **pituitary, adrenal, brain, leukocytes, and the eye.**
- **Functions:** These include:
  - **Formation of collagen** from procollagen. It is essential for **wound healing** and facilitates recovery from burns. It is needed for hydroxylation of proline to hydroxyproline (in protocollagen) and lysine to hydroxylysine (in mature collagen).
  - **Antioxidant properties:** Ascorbic acid is the **most active powerful reducing agent** controlling the redox potential within cells.
  - It is involved in intracellular electron transfer and supports **immune function**.
  - Promotes **absorption of nonheme iron**.
  - It is needed for the **formation of carnitine, hormones, neurotransmitters, and amino acids**.
  - Formation of **intercellular cement substances** in connective tissues, bones, and dentin, when defective, resulting in weakened capillaries with subsequent hemorrhage and defects in bone and related structures.
- **RDA:**
  - 15–45 mg daily in children
  - 75 mg/day for adult women
  - 90 mg/day for men
  - Pregnant or lactating women and the elderly have requirements up to 120 mg/day.

Deficiency of Vitamin C—Scurvy

- **Scurvy** is caused by deficiency of vitamin C.
- **Causes of vitamin C deficiency:**
  - Infants fed only on boiled cow's milk during the first year of life are at risk.
  - Individuals who do not eat vegetables such as elderly, people who live alone (singly) and chronic alcoholics.
  - Pregnant and lactating women and those with thyrotoxicosis require more vitamin C because of increased utilization.
  - **Individuals at risk of deficiency**:
    - Anorexia nervosa or anorexia from other diseases such as AIDS or cancer
    - Type 1 diabetes requires increased vitamin C
    - Patients undergoing peritoneal dialysis and hemodialysis
    - Diseases of small intestine such as Crohn's, Whipple's, and celiac disease.
  - **Types of scurvy:** Adult scurvy and infantile scurvy.

  - **Adult scurvy:** Early symptoms may be nonspecific, with malaise, weakness, lethargy and muscle pain (myalgias may be due to reduced production of carnitine).
    - **Bone disease:** More common in growing children and manifests after 1–3 months. It is characterized by **deranged formation of osteoid matrix and *bone pain*. Fractures, dislocations**, and tenderness of bones are common in children.
    - **Hemorrhages:** Hemorrhaging is a **hallmark** feature of scurvy and can occur in any organ. Hair follicles are one of the common sites of cutaneous bleeding. Marked tendency to bleed into the skin (easy **bruising, petechiae, ecchymosis, perifollicular hemorrhages**), bleeding into muscles, joints and underneath peritoneum. Bruising and hemorrhage may be spontaneous. Most commonly on the **legs and buttocks** where hydrostatic pressure is the greatest.
    - **Delayed/poor wound healing** and breakdown of old scars.
    - **Anemia:** It may cause high-output heart failure.
    - **Gums:** Inflamed spongy gums (**gum swelling**) friability, bleeding and infection with loosening of teeth; mucosal petechiae are common.
    - **Skin changes:** Roughness, keratosis of hair follicles with 'corkscrew' hair, perifollicular hemorrhages.
    - **Nails:** Splinter hemorrhages.
    - **Other features:** Emotional changes, shortness of breath.
- **Infantile scurvy (Barlow's disease):**
  - **Subperiosteal hemorrhage** into shafts of long bones.
  - **Scorbutic rosary** denotes enlargement of costochondral junctions, which are tender.
  - May be associated with **pectus excavatum**.
  - Retrobulbar, subarachnoid, and intracerebral **hemorrhages.**
  - Painful limbs giving rise to **'pseudoparalysis'**.
- **Laboratory investigations and diagnosis:**
  - Diagnosis is usually made **clinically** in a patient who has skin or gingival signs and is at risk of vitamin C deficiency.
  - **Plasma and leukocyte vitamin C** levels can be measured.
    - Leukocyte vitamin C levels are more reliable as recent treatment will improve plasma levels but tissues will still be deficient in vitamin C.
    - **Plasma vitamin C level** of <11 μmol/L (0.2 mg/100 mL).
    - **Anemia:** It can be normochromic, normocytic (due to bleeding), megaloblastic (due to reduced erythropoiesis) or microcytic hypochromic anemia (due to impaired iron absorption and impaired heme synthesis).
    - **Hess' capillary fragility** test can be checked by inflating a blood pressure cuff and looking for petechiae on the forearm.
    - **Bleeding time, clotting time, and prothrombin time:** To rule out other bleeding disorders.
  - **Imaging studies:** The findings include:
    - Loss of trabeculae results in a ground-glass appearance
    - Thinning of cortex
    - A line of calcified, irregular cartilage **(white line of Frankel)** may be visible at the metaphysis.
    - The epiphysis may be compressed and circular calcification surrounding epiphyseal center of ossification **(Wimberger's ring sign) (Fig. 15.4).**
- **Toxicity:**
  - **Acute:** High doses >2 g of vitamin C— abdominal pain, diarrhea, nausea.
  - **Chronic:**
    - Increased prevalence of kidney stones.
    - Iron overload—can cause fatal arrhythmias.
    - Hemolysis in G6PD deficiency.
    - False-negative guaiac reactions and interference with tests for urinary glucose.
    - Interference with activity of certain drugs—such as bortezomib in myeloma.

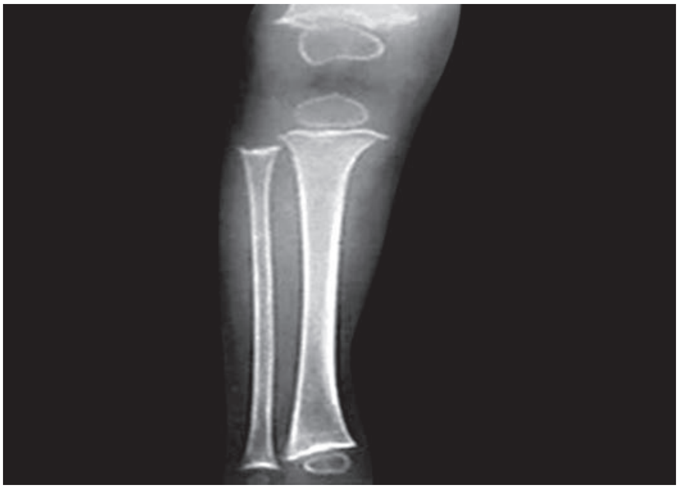

FIG. 15.4: X-ray of scurvy showing Frankel line and Wimberger's ring sign.

Management/Treatment

- **Ascorbic acid at 100 mg 3–5 times a day** until total of 4 g is reached, and then reduce the dose to 100 mg daily.
- **Encourage consumption of foods with high vitamin C**.
  - Citrus **fruits,** especially grapefruits and lemons.
  - **Vegetables**, including broccoli, green peppers, tomatoes, potatoes, and cabbage.
  - The recommended dose for adults is 120 mg daily, although a dose of 60 mg daily is all that is required to prevent scurvy.
  - Diets high in vitamin C may lower the incidence of certain cancers, particularly esophageal and gastric cancers.
  - Vitamin C supplementation can be useful in upper respiratory tract infections, Chediak-Higashi syndrome, and osteogenesis imperfecta.
  - There is inconclusive evidence of the protective role of vitamin C in the management of COVID-19 pneumonia.

VITAMIN D

Q. IM23.3 Discuss and describe the etiology, causes, clinical manifestations, complications, diagnosis and management of vitamin D deficiency.

- Vitamin D is a **fat-soluble secosteroid** responsible for enhancing **intestinal absorption of calcium, iron, magnesium, phosphate, and zinc.**
- **Physiology (Fig. 15.5)**
  - **Vitamin D$_3$ (cholecalciferol)**
    - Produced in skin with direct sunlight. Cod liver oil is a rich source.
    - Preferred form of supplementation
  - **Vitamin D$_2$ (ergocalciferol)**
    - Less effective as precursor to 1,25(OH)$_2$-vitamin D
    - Hepatic conversion of vitamin D$_3$ to 25-OH-vitamin D (calcitriol)
    - Conversion of 25-OH-vitamin D to 1,25(OH)$_2$-vitamin D (calcitriol)

• Induces differentiation
• Inhibits angiogenesis

FIG. 15.5: Physiology of vitamin D.

- **Functions:** Vitamin D exists in two activated sterol forms. Its functions include:
    - **Regulation of plasma levels of calcium and phosphorus:** The main functions of 1,25-dihydroxyvitamin D on calcium and phosphorus homeostasis are:
        - **Stimulates intestinal absorption of calcium:** 1,25-dihydroxyvitamin D stimulates intestinal absorption of calcium in the duodenum through the interaction of 1,25-dihydroxyvitamin D with nuclear vitamin D receptor.
        - **Stimulates calcium reabsorption in the kidney:** 1,25-dihydroxyvitamin D increases calcium influx in distal tubules of the kidney.
        - **Interaction with PTH in the regulation of blood calcium**.
        - **Mineralization of bone:** Vitamin D plays a role in the **mineralization of osteoid matrix** and **epiphyseal cartilage** in both flat and long bones. Vitamin D stimulates osteoblasts to produce the calcium-binding protein osteocalcin, which is involved in the **deposition of calcium** during development of bone.
    - **Antiproliferative effects:** The vitamin D receptor (VDR) is expressed in the parathyroid gland, and 1,25$(OH)_2$ D has an antiproliferative effect on parathyroid cells and it suppresses the transcription of the parathyroid hormone gene.
    - **Immunomodulatory:** Vitamin D is involved in the **innate and adaptive immune system**.

Vitamin D Deficiency

Q. PE12.7 Describe the causes, clinical features, diagnosis and management of deficiency/excess of vitamin D (rickets).

Causes of vitamin D deficiency are listed in **Box 15.4.** Diseases caused due to vitamin D deficiency are:

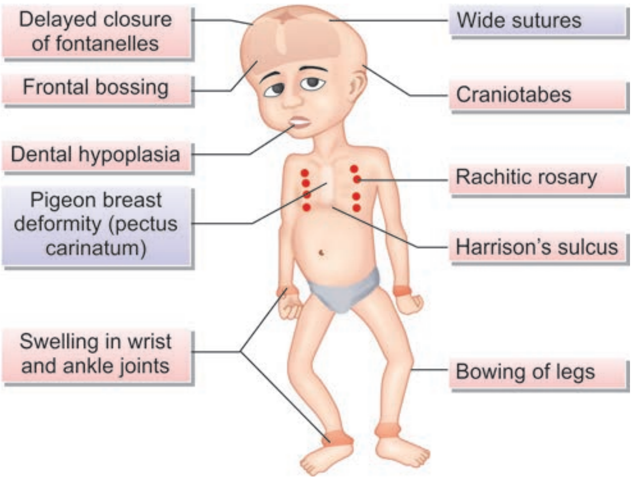
- **In children:** Deficiency of vitamin D in a growing child before the epiphyses has fused results in failure of growing bone to mineralize.
    - **Rickets:** Bone *softening* disease, deformity of *long bones* occurs.
- **In adults:**
    - **Osteomalacia:** Bone-thinning disorder, proximal muscle weakness, and bone fragility.
    - **Osteoporosis:** Decrease of bone mineralization and increased bone fragility.

Box 15.4: Causes of vitamin D deficiency.

- Impaired cutaneous production due to limited exposure to sunlight
- *Dietary absence*: Diets deficient in calcium and vitamin D
- Malabsorption
- Impaired hydroxylation by the liver to produce 25-hydroxyvitamin D
- Impaired hydroxylation by the kidneys to produce 1,25-dihydroxyvitamin D (vitamin D-dependent rickets type 1, chronic renal insufficiency)
- End-organ insensitivity to vitamin D metabolites [hereditary vitamin D-resistant rickets (HVDRR), vitamin D-dependent rickets type 2]

Rickets in Children (Fig. 15.6)

- In children, before the closure of epiphyses, vitamin D deficiency causes retardation of growth associated with an expansion of the growth plate known as **rickets.**
- **Gross skeletal changes in rickets** depend on the severity and duration of the vitamin D deficiency and also the stresses to which individual bones are subjected.
- **During the nonambulatory stage of infancy**
    - **Head:**
        - **Craniotabes:** The skull appears square and box-like, there is delayed closure of anterior fontanelle, frontal and parietal bossing.
        - **Frontal bossing:** Excess of osteoid produces frontal bossing and a squared appearance to the head.
        - Delayed eruption of primary teeth, enamel defects, and caries teeth.
    - **Chest:**
        - **Rachitic rosary:** Overgrowth of cartilage or osteoid tissue at the costochondral junction causes deformation of the chest producing the **'rachitic rosary'.**
        - **Pigeon breast/chest deformity:** The weakened metaphyseal areas of the ribs are subject to the pull of the respiratory muscles and thus bend inward. This creates anterior protrusion of the sternum producing **pigeon breast deformity** (pectus carinatum).



Delayed closure of fontanelles
Wide sutures
Frontal bossing
Craniotabes
Dental hypoplasia
Rachitic rosary
Pigeon breast deformity (pectus carinatum)
Harrison's sulcus
Swelling in wrist and ankle joints
Bowing of legs

FIG. 15.6: Features of rickets.

    - ♦ **Harrison's sulcus/groove:** It is due to the muscular pull of the diaphragmatic attachments to the lower ribs.
    - ♦ Respiratory infections and atelectasis.
- **During the ambulatory stage**
  - ▪ This occurs when an ambulating child develops rickets. It is characterized by deformities affecting the spine, pelvis, and tibia. Scoliosis, kyphosis, and lumbar lordosis are characteristic.
  - ▪ **Bowing of the legs:** Due to affection of tibia, knock knees, anterior curving of legs.
- **Extraskeletal manifestations**
  - ▪ **Seizures and tetany:** Secondary to hypocalcemia in vitamin D deficiency rickets.
  - ▪ **Hypotonia and delayed motor development:** In rickets developing during infancy.
  - ▪ Protuberant abdomen, bone pain, waddling gait, and fatigue.
- **Asymptomatic:** Detected on radiological evaluation.
- **Investigations**
  - ▪ **Wrist radiograph:** Findings include:
    - ♦ Lower ends of the shaft of radius and ulna become splayed.
    - ♦ Epiphyseal surfaces—fuzzy and ill-defined.
    - ♦ Unossified zone between shaft and radial epiphysis gets widened ('saucer' deformity).
- **Figure 15.7** shows a child with bow legs and X-ray **showing splaying, fraying and cupping of metaphysis**.
  - ▪ **Blood:**
    - ♦ **Serum calcium:** Low.
    - ♦ **Serum phosphate:** Low (due to associated secondary hyperparathyroidism).
    - ♦ **Serum alkaline phosphatase:** Increased due to increased osteoblast activity.
    - ♦ **Plasma 25-hydroxyvitamin D_3 level: Low** in most of the cases.

  Comparison of conditions involving bone metabolism is presented in **Table 15.5**.

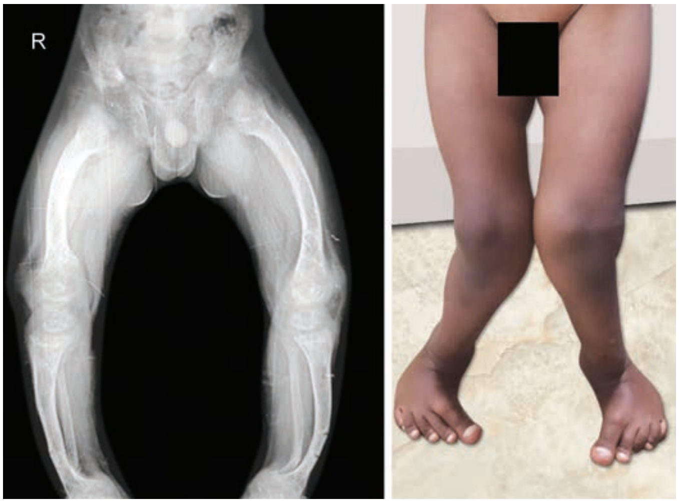


FIG. 15.7: X-ray of rickets showing splaying of epiphyses and bow legs.
